de W2NSD/1

The other day an amateur stopped by for a short visit to 73 headquarters and mentioned that he had been conducting an investigation of our bands and had discovered that many of the contacts that were going on seemed to be rather pointless. Frankly I have to admit that this is not the first time that I've heard rumors about this.

When something like this develops to the point where we become aware of it here at 73 we like to see what we can do to correct it before it turns into a trend and the ARRL requests the FCC to legislate against it.

The first step, obviously, was to conduct a survey and try to find out the extent of the incipient trouble. The entire 73 staff was pressed into service on an intensive investigation of our bands. I am happy to report that our figures show that only about 98.7% of the contacts on the amateur bands are dull and boring both to the participants and the non-participating listeners. This was an encouraging discovery since first estimates had placed the figure somewhere over 99.3%.

A well known amateur psychiatrist was consulted and he pointed out that even though the contacts are obviously almost totally without content that they fulfill a basic need to communicate and thus do serve to satisfy a subconscious need. He went on to say that the vacuity of the contacts seems to eventually become evident to the participants on some level of awareness and that this has a strong tendency to decrease their activity, eventually terminating their amateur activities completely. After a few years of freedom from the deadening dullness of the average radio contacts many amateurs, driven by the subconscious need to communicate, find themselves getting back into their old hobby. The pattern repeats itself.

Pressed for some explanation for the dullness of contacts, our psychiatrist friend revealed that this results from a common but little-noticed phenomenon: mike fright. In the case of the CW operator it might be called key fright. It is a manifestation of the broadcast radio obsession against having any dead air. The operator is so afraid that he will not be able to think of something to talk about that he is actually unable to think of something to talk about. To fill in the time he does the obvious thing, he recites a list of the equipment that he is using and discusses the weather. Then, with a great sigh of relief, he turns it over to the other fellow. The other chap does exactly the same, leaving operator number one with nothing whatever to comment on and the prospect of either sitting there with his transmitter on trying to think of something to talk about or else asking for a QSL and signing off.

The pattern, which apparently had its roots in the early days of amateur radio, may just possibly be broken. Perhaps it is worth a try. Actually the difficulty isn't all that different from the everyday efforts we make to communicate with people in our business and family worlds. Cocktail parties can be murder if you don't know some secrets for getting people to talk. Despite articles in the Reader's Digest and in many books telling us that the way to open any conversation is to merely get the other fellow to talk about himself, we seem to forget this basic rule. I've tried this on the air many times and it has seldom failed to open up an interesting QSO. I ask about the line of work and any other interests or hobbies . . . and the lid is off. Of course this means that you have to be good at listening. If you have a good set of your own interests the chances are that you will find a common subject that you can hash over with enjoyment. If not, then perhaps you can get your contact to tell you about somebody he knows that interests you.

Still, this is a hap-hazard system. Perhaps it can be developed a bit into something less chancy. Wouldn't it be nice if you could dial a frequency and find fellows there that share your interests? Ham pilots seem to enjoy swapping stories with other pilots when they chance to get together on the air. How about setting up a "net" frequency of pilots?

There are thousands of ham boaters, stinkpot and windy types. Some like houseboats, some water ski, some skin dive, some race.

The Suppressor Compressor

The Neglected Grid

Allan S. Joffe W3KBM
531 E. Durham St.
Phila., Penna. 19119

We hams, just like most people, are prone to be creatures of habit. To illustrate my own personal groove, consider the pentode, a tube with three lovely grids plus other assorted parts. All my life I have fed a signal into the control grid, tied the screen to some B plus point and consigned the suppressor to ground or the top of the cathode bias resistor. There came the day when the painful process of thinking turned me out from my rut of indifference with interesting results. I knew from past tinkering that the screen was useful to control low frequency response in modulators and the like via the selective bypassing route. This in itself was perhaps the beginning of shrugging off old devil habit as the approach was a change from bypassing the screen and forgetting it. I decided to explore the personality of the suppressor and thereby hangs the tale.

The junk box supplied a small chassis with three octal sockets, to serve as a breadboard. The tube locker provided a 6SJ7 as the available pentode with the suppressor coming out to its own pin rather than being internally connected to some other element. As a jumping off point, I wired up the tube with average parts values for the tube used as an audio voltage amplifier as shown in **Fig. 1.**

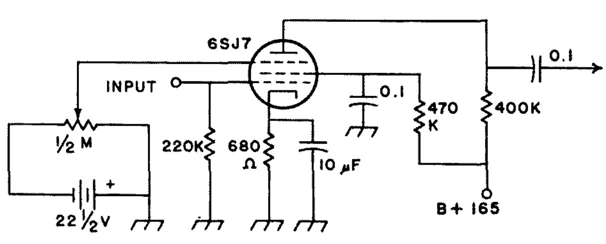

Fig. 1. Basic circuit of the Compressor, showing how a DC control voltage is applied to the suppressor *grid to control tube gain.*

Naturally the 22½ volt battery and the pot across it are not what you expect to find the well dressed voltage amplifier wearing but they were necessary to get some idea of what the suppressor characteristics would be. Increasing negative voltage on the suppressor brought to light one of those self evident truths "we all know". As the suppressor went more negative the plate voltage rose and the screen voltage fell. A little cogitating on the location of the suppressor, between the screen and the plate explains the foregoing. As the negative suppressor shuts off the electron stream to the plate, the screen becomes the dominant attractor, its current goes up and the voltage drop through the screen resistor goes up. Ergo! Since the project now showed promise of improving my education I forged on. The next addition was to be a triode amplifier following the pentode stage so that I could get enough voltage, signal wise, to use my db meter. With the addition of a 6J5 triode the circuit now looked like **Fig. 2.**

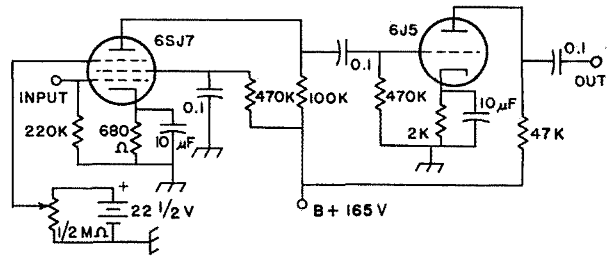

Fig. 2. This arrangement would be appropriate for remote control of audio gain. It has an effective control range of better than 20 *db.*

Feeding a 1 kHz signal into the input, the output was set at ten volts. If we can believe the attenuator of my audio generator it took about 8 millivolts input to produce the ten volts output which seems about reasonable from past experience. This overall gain figure was produced with the 6SJ7 suppressor at ground potential. The negative potential on the suppressor was now increased in two volt steps and the effect on the output was noted and recorded for posterity in **Fig. 3**

At this juncture in the proceedings it was about time to decide what I was building and where it was going. An electronic

Fig. 3. Control characteristics of the circuit of Fig. 2. Remember to include a switch in the battery circuit to increase battery life.

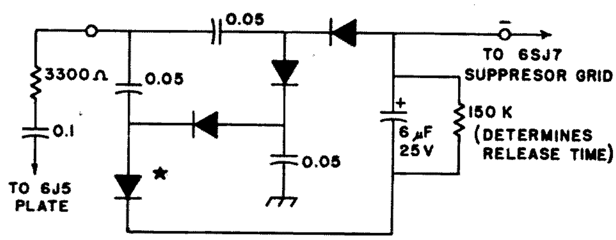

Fig. 4. An audio voltage-quadrupler circuit to develop the fedback control voltage in voltage compressor applications. It will offer a fast attack and slow decay.

primitive giving birth to a brain child can swing in many directions but the vine I grabbed led down the road marked "Audio Compressor". To quote from the Good Book, "You can derive a voltage from the audio signal and apply it to a suitable electrode in such a manner that the output signal will stay within proscribed limits when the input signal varies within reasonable limits". I felt that the suppressor grid would be a great "control electrode" and now all I had to do was derive a control voltage from the audio signal. If all the ideas I rejected to derive the control signal were detailed this article would rival *Gone Wih The Wind* in length. Naturally I realized the control signal needed would have to be dc in nature for simplicity and to avoid phase shift and feedback troubles associated with ac control signals. This led to the implication that I would need some sort of rectifier circuit but one with gain, if you please. The philosophy (a term meaning knowledge gained through hindsight) behind this decision was reached upon concluding the following.

A—the unit already had two tubes, and I am fond of even numbers.

B—I planned to pad the output of the little wonder down so it would feed proper level into existing mike gain stages, so high level signal voltages would not be available to me without tapping into the high level audio stages that followed the regular mike inputs. This was too cumbersome an approach so the control voltage had to be derived from the circuit as it now stood.

C—Referring to the chart of Suppressor Bias versus Audio output (**Fig. 3**) indicated a need for up to 20 volts of control signal.

Since the 6J5 very easily provided in excess of ten clean volts of signal, I decided to use one of the standard voltage multiplying rectifier circuits, winding up finally with a voltage quadrupler as shown in **Fig. 4**. The choice of the quadrupler was made so that the voltage needed could be obtained at the same time that a reasonable amount of isolation could be put between the 6J5 plate circuit and the rectifier circuit to avoid lousing up the audio because of varying loading produced by the rectifier over the ac cycle and to avoid feeding any generated audio harmonics produced by the rectifiers presence to the following aduio stages. The 3300 ohm resistor and the 0.1 mF blocking condenser feeding the audio from the 6J5 plate to the voltage quadrupler was determined experimentally to be a fair compromise between isolation as discussed and attaining the needed control voltage.

Fig. 4 shows the interesting fact that three of the voltage multipler condensers are small (0.05 mF) but that the output condenser is, by comparison, a fair sized electrolytic (6 mF) These values were chosen so that the quadrupler would quadruple, but the output voltage rate of decay would be rather completely under the control of the 150 K resistor shunted across the 6 mF output condenser.

Regretably, no epic dealing with an aduio compressor can fully bypass a small discussion of attack time (the speed at which the unit takes hold and compresses) and release or decay time (the time interval required to restore steady state circuit conditions when a good sized peak has become history). I candidly admit that I don't know the attack time of this little gem but blandly state that whatever it is, I must be doing

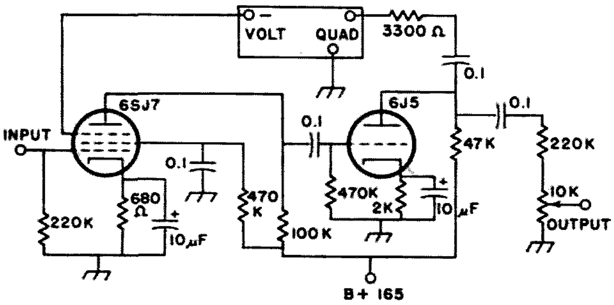

Fig. 5. The complete compressor circuit, with the quadrupler circuit replaced by the three-terminal box labeled "quad."

something right from the way it sounds in use.

The release time is easier to come by as you can readily time the decay of the control voltage by monitoring same with a VTVM and clocking the time of fall after hitting the input with a heavy "woof". The specified values give a release time of about 2½ seconds which works out well in practice for voice communication.

Fig. 5 gathers up all the pieces into the finished schematic of the practical functioning unit. For my own personal use (to feed my Gonset G-50) I used the output control circuit shown. There is no input gain control as the microphone used gives about 30 millivolts on close talking peaks. (a 100 millivolt signal will not overload the compressor or cause distortion). The audio to the G-50 is set by the output control on the compressor, which means that in normal use the compressor input is running wide open.

The Tabular data in **Fig. 6** is quite interesting. It shows the relationship between specific values of input signal, the resulting audio developed across the 6J5 plate load and the corresponding values of dc control voltage developed for application to the suppressor grid.

Notice that a change in input signal of 20 db (the range from 1 millivolt to 10 millivolts) gives an output change of about 13 db or a compression of about 7 db. If we push the input signal up to 30 millivolts (about 29.5 db over the reference 1 millivolt) then there is an effective compression of about 13 db. A 100 millivolt signal was applied experimentally with a recorded compression of some 21 db. The output as viewed on a scope was as clean as the signal produced by a 10 millivolt input signal.

Some parting thoughts in retrospect. Like most hams, my shack is not loaded with expensive test gear. The measuring equipment used was a Heath Audio VTVM, a standard 20,000 ohms per volt multimeter and an RCA Jr. Voltohmyst plus an ordinary 5 inch service type scope. Halfway through the first set of measurements I had the inspiration to see if the three meters involved agreed one with the other. Needless to say they did not and the work was stopped cold until they were shaped up. (How do your meters stack up for agreement?) Since my mill is an old one constructed before superlatives were invented I have nowhere stated that the subject of this article was "the best" or the living end.

As a matter of fact, after this project came to a satisfactory conclusion subsequent mental modifications suggested themselves and just beg for somebody to try them out. The thought was that the 6J5 could be replaced with a dual triode. One half would be nothing but the audio channel and the other half just the amplifier for the control voltage section. This would eliminate the RC isolation network across the present audio plate load and a point of possible distortion. A pot could be placed in the grid of the control amplifier triode to give easy control of compression if this were desired.

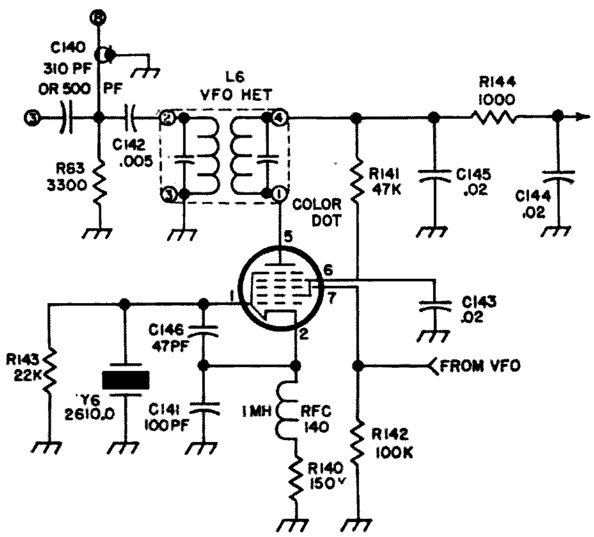
Putting the HW-12 on 160 Meters

Dean W. Manley W8FGB
P.O. Box 217
Escanaba, Michigan 49829



Carrier oscillator and heterodyne oscillator mixer

The SSB signal in the HW-12 is generated at 2.3 MHz and mixes with the 1.5-1.7 MHz VFO signal to get 3.8-4.0 MHz. After changing the VFO cathode follower, V14-6BE6 to a heterodyne oscillator mixer, the 1.5-1.7 MHz VFO mixes with the 2.6 MHz crystal oscillator. The output of the V14 Mixer is 4.1-4.3 MHz. When transmitting, the 2.3 MHz SSB signal is mixed with the 4.1-4.3 MHz in the V4-6AU6 xmtr mixer producing 1.8-2.0 MHz. When receiving, the incoming 1.8-2.0 MHz mixes with the 4.1-4.3 MHz from the V14 stage producing the *if* of 2.3 MHz. This conversion to 160 meters inverts the SSB signal. If we didn't change the crystal in the V11B-½12AT7 carrier oscillator stage, the converted HW-12 would respond only to upper sideband signals. This is easily remedied by changing the V11B stage crystal from 2306.7 kHz to 2303.3 kHz and the modified unit will respond to lower sideband (LSB) signals, both transmitting and receiving.

Transmitter driver and receiver rf

Modification of this part of the HW-12 only involves changing the L2-DRIVER GRID and L3-DRIVER PLATE coils. These coils also serve as *rf* stage coils in the receive mode. The coils are removed and modified, and then re-installed.

Transmitter pi-net

This portion of the modification affects only the transmitter section. The Pi-network tank variable C65, capacitors C66 and C67 (68 pf each), tank coil L4, and loading capacitor C77 are removed and their 160 meter equivalents are installed.

Whether you obtained your HW-12 new or used, the 160 meter modification should not be undertaken without reference to the Assembly Manual supplied with the kit. Not only is the manual helpful during the process of the modification, but it should be used to check the performance and alignment of the HW-12.

It is strongly suggested that time be taken before modification to measure and make a written record of voltages. Reference is particularly made to Figure 12 on page 52 and Figure 13 on page 53 of the HW-12 manual. Before the actual modification is started, make sure that the HW-12 performs normally on 3.8-4.0 MHz. This could very well save time and headaches later.

Parts needed for 160 meter modification

Besides the HW-12 and it's power supply, the following lists of parts is required for the 160 meter modification: (One of each required, unless otherwise specified)

2303.3 kHz crystal, Heath 404-196
80 Meter Driver Grid Coil, Heath 40-516
33 pF mica or ceramic capacitor
47 pF disc capacitor
56 pF, 4kv disc capacitor
100 pF disc capacitor

220 pF, 4kv disc capacitor
2000 pF (.002 mF), 500 volt mica capacitor
.02 mF disc capacitor
150-ohm, ½ watt, 10% resistor
1000-ohm, ½ watt, 10% resistor
22K, ½ watt, 10% resistor
1 mH *rf* choke
B&W Miniductor 3019 (see text)
Hammarlund MC-140-S transmitting variable
2610.0 kHz crystal, JAN Crystals (HC6/U holder)

Also, a small quantity of small size wire suitable for rewinding coils L2 and L3 is required. Sizes between #30 and #36 is suggested. The winding from an old 2.5 mH *rf* choke or a broadcast oscillator coil may be used. If it is decided that total coverage of the 160 meter band will not be used for transmitting, then the new 140 pF variable capacitor will not be required. The present final tank capacitor C65, 50-50 pF will cover at least one 25 kHz segment of the band. In this case, experimentation may be required for the exact values of the capacitors in parallel with the final tank variable to cover the desired 25 kHz segment of the 160 meter band.

It should be noted here that the new 80 meter Driver Grid Coil will be used for the Heterodyne Oscillator Mixer Coil L6 for 160 meter operation.

Modification

Carrier oscillator and heterodyne mixer

Remove the present carrier oscillator crystal Y1-2306.7 kHz and install the new crystal 2303.3 kHz. Remove the following parts from the V14-6BE6 VFO cathode follower: R140-1000, C141-310 pF, RFC-140-15 μH, and the jumper wire connecting V14-Pin 1 and Pin 7. Remove R141-47k and temporarily set aside for later installation.

Locate the new 80 meter driver grid coil (Heath 40-516) to be modified for use as L6 heterodyne oscillator mixer. Remove the coil from the shield can and then remove the 390 pF capacitor. Remove one end of the 100 pF capacitor and coil lead from pin 2. Remove the coil lead from pin 4 and solder it to pin 2. Now solder the free end of the 100 pF capacitor and the remaining coil lead to pin 4. Install a 33 pF capacitor between pin 2 and pin 3. Re-install the coil in the can and the install the completed L6 on the printed board between V13 and V14. Pin 1 of L6 goes to V14-pin 5.

See **Fig.** 1 for the installation of the parts in the het osc mixer. Double check to be sure of the proper location of each part before installing the part. Then install the part and check again for possible errors! It is easy to make errors, especially if you're not familiar with printed boards.

Locate C142-.005 on the printed board and remove the lead going to V14-pin 2. Connect this free end to L6- pin 2. Now locate C140-310 pF and remove the lead nearest V14. Connect the free end of coaxial cable, and R83-3300. Install the following parts: R140-150, R141-47K, R144-this capacitor to the junction of C142.005, 1000, R143-22k, C141-100 pF, C146-47 pF, C145.02, RFC140-1mH, and Y6-2610.0 kHz.

Driver coils L2 and L3

Remove L2 from the printed board and remove the shield can. Carefully add approximately 35 turns "Scramble-wound" to each winding. Wind over the present winding and away from the adjacent winding. Do not wind in the space between the primary and secondary windings. Check the windings with an ohmmeter and then re-install in the shield can noting the position of the color dot. Re-install L2 on the printed board.

Remove L3 from the printed board and remove the coil from it's can. Remove the windings, noting the pin connections. Wind a 6-turn link to pin 2 and pin 3 in the same location on the form as the original winding. Now wind approximately 85 turns over the link using the "scramble-winding" method and connect to pin 1 and pin 4. Check with an ohmmeter and then re-install in the shield can noting the color dot. Install L3 on the printed board.

Transmitter pi-net

Remove the following parts from the HW-12: 80 meter tank coil L4; final tank capacitors C65-Variable, C66-68 pF, C67-68 pF; and the loading capacitor C77-1000 pF.

Install the new C77-2000 pF capacitor in place of the old C77. Install the entire B&W 3019 Miniductor or wind 36½ turns of No. 16 enamel closewound on a 1¼-inch

diameter form 3-inches long. The winding will take up about 2-inches. Install the variable capacitor at the final tune location on the front panel. Install the fixed capacitors from the hot side of the variable capacitor to ground. The fixed capacitors are 220 pF and 56 pF at 4kv. Solder a lead from the top of coil L4 to the hot side of the tank capacitor combination C65-C66-C67.

Alignment

Follow the procedure outlined in the HW-12 manual for the alignment of the VFO dial calibration, bias setting, *if* amplifier adjustment, and balanced modulator adjustment.

Het OSC mixer alignment

1. With the VFO dial set to 1.8 (3.8), turn the function switch to the tune position and the meter switch to tune operate.

2. Adjust the upper slug of coil L6 for maximum output.

3. Set the VFO dial for 2.0 (4.) and adjust the bottom slug of L6 for maximum output.

4. Repeat steps 1, 2, and 3. If results are not satisfactory, try adjusting the upper slug at 2.0 and the bottom slug at 1.8

Driver alignment

1. Adjust the upper slug of driver grid coil L2 for maximum output at 1.8.

2. Adjust the bottom slug of L2 for maximum output at 2.0.

3. Adjust the slug of Driver plate coil L3 for maximum output at 1.9.

4. Repeat the steps as necessary for the desired results. If flat response across the entire band is not obtainable, then try for response across the desired 100 kHz portion of the band. For example: adjust one slug of L2 at 1.8, the other slug of L2 at 1.9. Adjust L3 at 1.85.

Now go back to L6 and adjust if necessary for response across the desired portion of the band.

Gratifying reports were received on 160 meters saying that the rig sound every bit as good as an unmodified unit on 75 meters.

Tuning a Parasitic Beam

Kayla Bloom W1EMV
P.O. Box 224
Dublin, N.H. 03444

Most antenna construction articles don't go into much detail on making tuning adjustments. If you are not familiar with the tuning details, it can take twice as long to tune the beam as it took to build it.

In spite of all the elaborate antenna designs which have been developed in recent years, the old grounded "Plumber's Delight" parasitic beam remains one of the most popular antennas for HF and VHF bands. Reasonable gain can be achieved with two or three element beams using .1 to .15 spacing of elements. Construction is easy and materials for building such a beam are readily available almost anywhere. It can be made rugged to withstand weather conditions and normally won't require any servicing once it is properly tuned and installed. Finally, with few exceptions, it provides much more satisfactory performance than antennas made of wire elements.

Among other advantages, we should also add that it is really easy to tune, both for forward gain and front to back, if you know the procedure.

We won't deal with construction details here, since those are available in handbooks, antenna handbooks, and in numerous articles which have appeared in ham magazines over the past years. Typically, these articles devote much time to construction of the beam itself, including the usual Gamma matching section, but only passing mention is made of the details of tuning adjusting for maximum performance.

To the experienced antenna builder, this article will be of little value. However, for the Novice or new ham, tuning a beam can be a frustrating experience which requires an inordinate amount of time, sweat, and even tears. Many a beam building project has been abandoned at this point, or has simply been put into service with less than optimum performance. I repeat . . . . tuning a beam is easy.

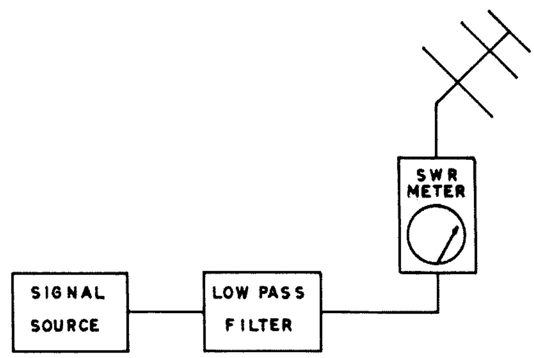

Fig. 1. Equipment diagram for driven element matching adjustments.

This article will deal with the single band, Gamma matched beam, and will show you how the beam can be tuned easily and quickly, to give you the best performance. After all, you are going to devote a good deal of time to constructing the beam, now, let's get the most out of it. Don't rush! There are certain pieces of equipment you will need to do a first class job. If you don't own them, borrow them. It is also helpful to have one other person to assist, but it can be done alone.

First, let me make one point clear. It is virtually impossible to achieve maximum forward gain and maximum front to back ratio on the same beam. The forward gain is determined primarily by the element spacing and the efficiency of the driven element. The front to back is determined by the length of directors and reflectors, although both are important in the case of forward gain. In nearly all cases a compromise must be reached if one factor is not to be sacrificed. However, the following procedures will usually give the best results without losing too much on either forward gain or front to back.

Test setup for matching adjustments

Once the beam has been constructed ac-

cording to the dimensions outlined in an article or antenna manual, the next step is to adjust the matching section on the driven element of the beam for correct matching to the transmission line. It is desirable to make these adjustments with the beam in its final location, but since this is usually a physical impossibility, the idea is to get it as far above ground as is possible. Keep it as far away from obstructions, especially large metal surfaces, as you can. For HF beams, a tall stepladder will suffice.

Correct matching conditions are indicated by obtaining the lowest SWR reading possible on the coax transmission line. As shown in **Fig. 1.**, the SWR meter should be located as close as possible to the antenna end, not the transmitter end of the transmission line. There are two reasons for this. First of all, if the transmission line has any appreciable losses, a false reading will occur at the transmitter site and usually will appear better than the actual situation at the feed point of the antenna. Secondly, you will want to be in a position to observe the readings on the SWR meter as you are making the adjustments in the matching device. Therefore, you will need a SWR indicator of one type or another. This can vary from a simple home-brew "Monimatch" which will cost pennies to construct, to an elaborate commercial Wattmeter which will cost more than pennies. Since we are concerned with the power getting to the antenna and the amount being reflected back to the transmitter, any reliable SWR indicator is acceptable.

An absolute minimum of connectors should be used in the coax line, including those used at the SWR meter. While new connectors usually don't introduce significant loss, each one is a potential source of future problems due to corrosion, etc. There rarely is a need for a connector at the antenna feed point, and a soldered (not twisted) pigtail connection is best. Soldered pigtail connections should definitely be used during adjustments.

The transmitter, or other signal source, must first be properly matched to the transmission line. A dummy load at the antenna end, with the SWR bridge at the transmitter end will confirm this match. Once the transmitter is tuned up with the dummy load, these adjustments should not be changed throughout the entire tuning procedure. **Fig. 1.** shows a low pass filter at the transmitter end because harmonics fed to the antenna will cause false readings. Most present day transmitters have harmonic content low enough to prevent any problems, but some harmonics are always present and unless you use an expensive signal generator as the power source, the use of a low pass filter is a necessity. Most of the less expensive signal generators have, at best, a broadly tuned output circuit and the harmonic content can be high.

Now what about the accuracy of the SWR bridge? If you were able to achieve close to a 1:1 ratio with the Dummy load at the antenna and the SWR indicator at the transmitter, it is reasonable to assume it is correctly calibrated.

Adjusting the matching section

Most beam of this type use the Gamma matching section shown in **Fig. 2A,** although the Delta match shown in **Fig. 2B** does have some advantages, and is still used in some construction. There are several ways to explain the action of the Gamma match. One concept is that the loop 1-2-3-4 induces a voltage in antenna section 1-2 which is then coupled to the rest of the driven element. Since the loop 1-2-3-4 is not large enough to be resonant, its inductive reactance must be cancelled out by the series capacitor in leg 3-4. As long as legs 1-2 and 3-4 are reasonably closely spaced, they act similar to a transmission line, and no radiation occurs from the matching section.

Generally the dimensions chosen for the

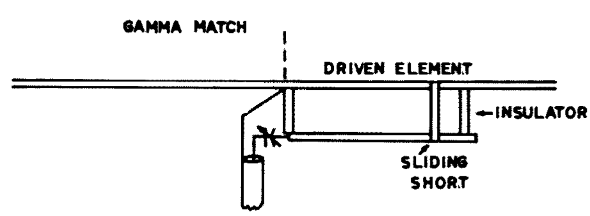

Fig. 2. (A) Basic form of Gamma match and (B) Delta match.

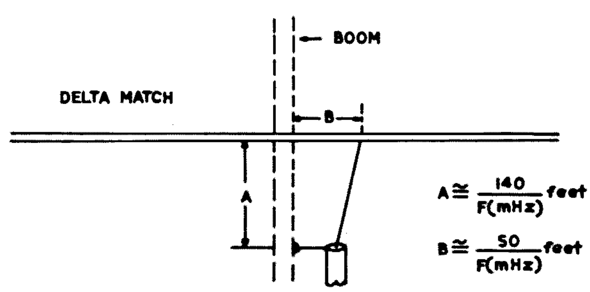

Gamma section are such that its length is from 1/10 to 1/16 of a wavelength and the spacing between sections is 1/30 to 1/60 of a wavelength with the maximum value of the series capacitor in pF being 7 times the wavelength in meters.

The adjustment now depends upon whether you have built the beam from the dimensions given in a construction article in a magazine or manual, or whether it is an individual creation. In the first case, assuming a series capacitor has been used in the Gamma match, the procedure is as follows.

1. Using a transmitter or rf signal generator, excite the antenna with sufficient power to obtain a reasonable indication on the SWR meter.
2. Adjust the sliding short for minimum SWR, or at least a decrease in SWR reading.
3. Adjust the series capacitor for minimum SWR reading.
4. Go back and forth between steps 2 and 3 to get minimum SWR indication. The SWR *must* go through a rise-dip-rise-dip sequence.
5. After the minimum possible SWR indication has been obtained, adjust the driven element length (try lengthening first for a further reduction in SWR indication. This is fairly critical and on a HF beam should not be more than a few inches in length. Remember, at this point the reflector and director(s) should not be adjusted.
6. Finally, double check the final SWR reading by going through the calibrate procedures for the type of SWR meter used.

In the case of an individually designed beam, where we assume dimensions are pretty close to "text book" specifications, (both spacing and element lengths) it is a good idea to check the frequency resonance of the driven element first. Where there is a difference in element diameter, the resonant frequency of the driven element may be far from the expected value. The Gamma match section may be connected in some temporary way and the signal source frequency varied to check to see that a broad SWR dip occurs near the desired frequency. Here we find a grid-dip meter to be an invaluable aid. With the feedline disconnected and a few inches of wire attached to the feed point of the driven element and loosely coiled around the grid-dip meter coil, a pronounced dip will occur at the resonant frequency of the driven element. Be careful here, because other minor dips may occur. There is no point in continuing with the matching section adjustments until the resonant frequency of the driven element is established. Once this has been determined, the same steps should be followed as outlined for the other version.

If you want to eliminate the difficulties usually encountered by the use of a series capacitor in the Gamma leg, this too can be accomplished simply. Instead of using step 3 in the sequence, vary either the spacing between the Gamma section and the driven element, or vary the diameter of the Gamma section. This requires the patience of a Saint, and the SWR may never reach the desired 1:1. However, if you get close (1.2 or 1.3:1) it is worthwhile to accept the adjustment and gain the advantage of not having another component, way up there on the tower or mast, which could ultimately break down and cause problems.

The Delta match is appealing because of its simplicity, but it can prove more difficult to adjust. It is possible to simply use the center conductor of the transmission line on the Delta match leg. The dimensions shown in **Fig. 2B** should be considered to be approximate and merely as a crude starting point. Once the driven element has been adjusted for resonant frequency, the adjustment of the Delta match follows much the same procedure as that for the Gamma match. Instead of adjusting matching section length and spacing, however, dimension A and B of **Fig. 2B** are adjusted for minimum SWR. The procedure is time consuming and tedious, however, and spare coaxial cable should be allowed in the event that, on the first try, too much of the center conductor is cut away. On the other hand, the end result is an extremely simple, highly reliable feed system.

Adjusting the parasitic elements

These adjustments don't necessarily have to be made. Most beams, when cut to "text book" dimensions, will perform well. However, there is always the goal of producing the last db of possible performance from a beam. If properly constructed in the same manner, and of the same materials, there is every likelihood that the proper frequency relationship will be retained. The reflector should be 5% longer than the driven ele-

ment, and the director should be 4% shorter. Each additional director should be made successively 4% shorter until the third director element when the length remains constant for any additional elements.

Here we get into the compromise situation between forward gain and front to back ratio. This, of course, depends on the individual's wishes in the matter. In some areas of the country the front to back is less important than in others. Forward gain is the prime factor. In others, the curtain of signals coming in from the back of the beam, may make the difference in hearing a DX station and not hearing him. Having lived in Hawaii, Colorado, and now the East Coast, there are three sets of circumstances and my beam tuning has changed with the circumstances.

In Hawaii, there was little QRM from the West, but an iron curtain of Western U.S. stations to the East. There, forward gain was important. In Colorado, where QRM came from both East and West, front to back ratio was important if I wanted to hear the incoming signals. Here in the East, I find a compromise situation must be achieved. The individual will have to make his own decision as to this approach to efficiency. In many cases, the loss of a db or two in forward gain is worth the added attentuation of signals coming in off the back of the beam.

Tuning for maximum forward gain

A field strength meter is placed at least two full wavelengths directly in front of the director's path. A short horizontal dipole connected to the field strength meter is best, but a vertical antenna will work reasonably well in these measurements. The beam is excited and a reading taken. Here is where the second person can be utilized to take the readings. However, I have found good results using a pair of good binoculars or even a telescope to make the readings alone. A telescope allows readings from a greater distance, but at two wavelengths, binoculars will do well. The meter should be isolated from reflecting surfaces and should not be held by another person. After an initial setting is obtained, the meter adjustments should not be changed. The beam's reflector and/or directors should slowly be changed in length for maximum indication on the meter. These adjustments will be

broad, but should show a definite rise and fall in the meter reading with changes in length. Continue this process until maximum field strength readings are obtained.

Tuning for maximum front to back ratio

To achieve maximum front to back ratio, follow the same procedures described for forward gain, but have the reflector element facing the field strength meter. The reflector element should be adjusted for a minimum dip on the field strength meter. This dip should be quite sharp as small changes are made on the reflector length. The director should be then adjusted for a null on the field strength indicator. This adjustment will be much broader than that of the reflector.

A compromise between forward gain and front to back ratio can only be made with a three element (or larger) beam, and requires a combination of the previous procedures. Basically, the directors are first adjusted for maximum forward gain (first adjusting the director nearest the driven element) then the beam is turned 180° and the reflector is adjusted for minimum field strength reading. The director(s) is not readjusted.

In all these adjustments, low power should be used not only to reduce the physical problem of *rf* "tingles" and/or possible burns, but to reduce the QRM radiated on the given band. Use only the amount of power required to produce adequate readings. If working alone, it would be wise to locate the transmitter or signal source where it can be kept under control at all times.

After all these adjustments have been made, it is a good idea to check the driven element SWR again, especially if the transmission line has been removed from the beam at any time. Unless the parasitic elements have been changed drastically, there should be no significant change in SWR. It may have improved somewhat in the process. However, a final check is in order before removing the test equipment and permanently installing the beam at the top of the tower.

One final word. I have found it to be more successful in the tuning of the driven element to remove it from the beam and isolate it for the initial tuning. Make believe you have a dipole antenna and tune it as if it were the only antenna you were going to use. Then reassemble it on the boom and make the other tests. This is minor, I assure you, but if you are looking for that last db of efficiency, it can mean a JND (just noticeable difference).

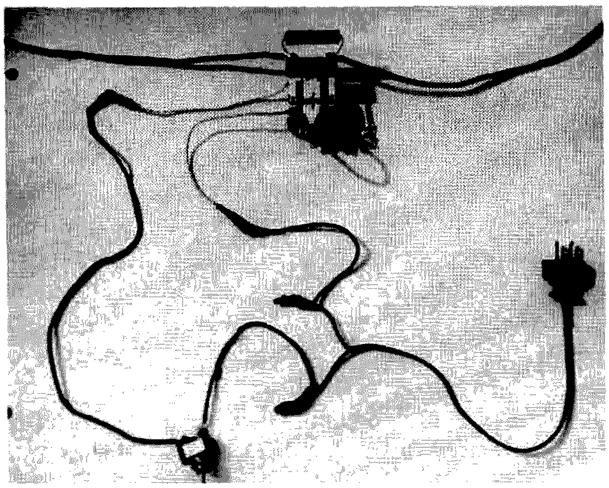
Does Your Linear Need Help?



Mockup of the modification. Plate supply ground return contains a 5000 ohm resistor, shunted by the normally closed relay contacts.

Has your linear started blowing fuses when you turn the plate switch on to tune up? Or maybe the mercury-vapor tubes inside are frequently flashing a bright bluish-purple? Could be you have heard a disturbing "thump" from the power transformer as well!

You may know about a cold pill to cure wheezing, sneezing, and assorted miseries, but would you believe one simple modification to your rig can end fuse blowing, tube flashing, and transformer thumping all at once?

These troubles may start as you turn on the plate switch of the linear if the sine wave of the alternating supply is almost to a peak. This causes the rectifiers to send an enormous inrush of direct current to the starved filter capacitors. Even if a fuse doesn't blow, this surge won't do the mercury vapor tubes a bit of good. And the jarring thump of the transformer may shake you up so much that you miss that choice DX station who just called CQ on the frequency where you're listening.

The filter in my factory-built linear consisted of six 100 μF capacitors in series with equalizing resistors across each one. I merely opened the low potential lead from the grounded center-tap of the plate transformer and inserted a 5000 ohm, 20 watt resistor in series. Then I connected a relay with normally-closed contacts in parallel with the resistor with a jumper to short circuit it. The primary coil of the relay is operated by a toggle switch mounted on the front panel. The 120 volts ac for this is picked up where the line enters the cabinet and is protected by the unit fuse, of course. The 5000 ohm resistor is permanently wired in the circuit. Whether the relay is energized or not, there is no time when the center-tap of the plate power transformer is open. Be sure your relay is wired in this manner.

When the fialment switch is closed, the mercury vapors heat; then, the modification switch is closed, and the relay removes the short circuit from the 5000 ohm resistor. When plate power is turned on, this extra resistance allows the filter capacitors to charge more slowly. You will notice a momentary brightening of the mercury vapor tubes but no flash, no thump, and no blown fuse.

After opening the modification switch, you're all set to call and work that DX station, so get after it!

. . .W9VEY

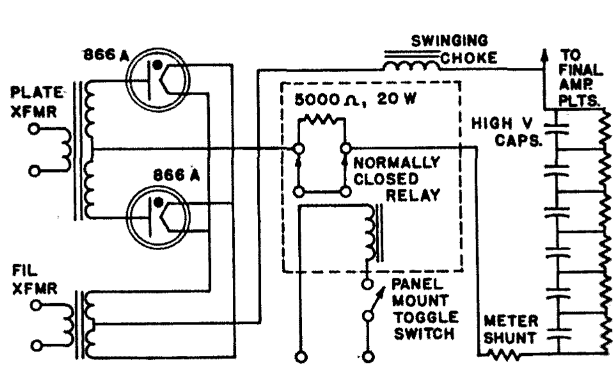


Fig. 1. Modification shown within dashed lines prevents quick inrush of charging current to capacitors. This reduces strain on fuses and mercury vapor rectifiers. Also good for semi-conductor rectifiers.

Some Thoughts on Voltage Control

Murray Ronald VE4RE
Box 974
Brandon, Manitoba
Canada

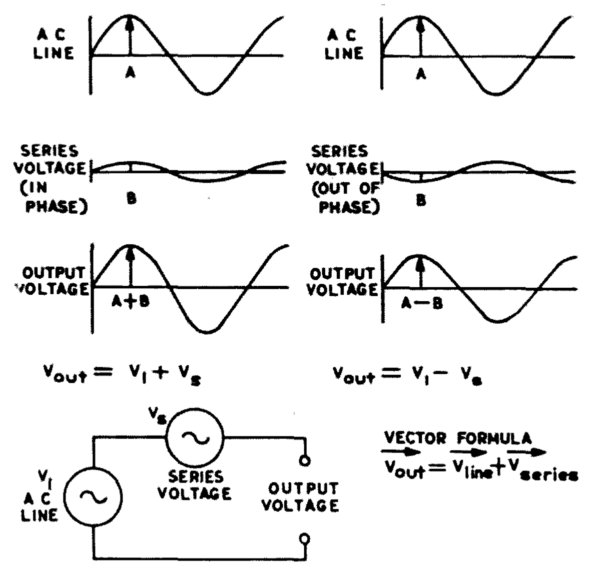

Fig. 1 Boost/Buck system of voltage control. V1 and Vs must be of same frequency sine-wave output to preserve.

An earlier article[1] by Jim Kyle, concerning adjustment of an ac line voltage by the "Boost/Buck" system, prompted some further thought and experimentation along a similar line. Although the underlying theory of the system described by Kyle simply involves vectorial addition of two ac voltages of the same frequency, there is some tendency to confuse it with the system of **Fig. 2.** The boost-buck system explained in **Fig. 1** is often used in small line voltage regulators for field day use, the series voltage being derived from a step-down transformer whose primary is paralleled with the ac line voltage. **Fig. 3** shows such a system. Since the phase shift across the transformer is 180 degrees (or nearly so) the series voltage can be made to boost or to buck the input voltage with a reversal of either the primary or secondary transformer leads. For the in-phase case the vectorial addition of **Fig. 1** becomes simple addition; and for the out-of-phase case the resultant voltage is the difference of the other two.

The system illustrated in **Fig. 2** involves changes in the magnetic flux densities of the transformer core. This method may be used to vary the output voltage of a dc supply of the transformer type. Basically then, if a secondary winding is connected with the transformer primary in "series-aiding" the flux density due to the primary current tends to be greater. This translates into increased voltage induced in any other windings. Conversely, the flux density would decrease should the two windings be connected in a "series-opposing" fashion. **Fig. 5** diagrams a dc power supply which employs this technique.

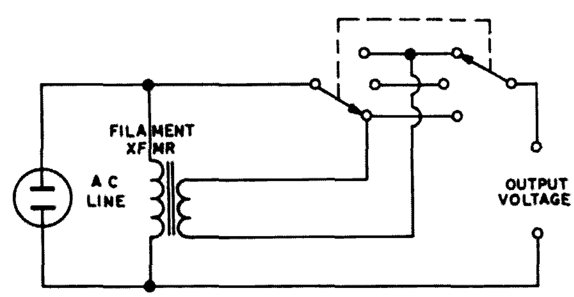

Fig. 3. Practical "Boost/Buck" manual voltage controller.

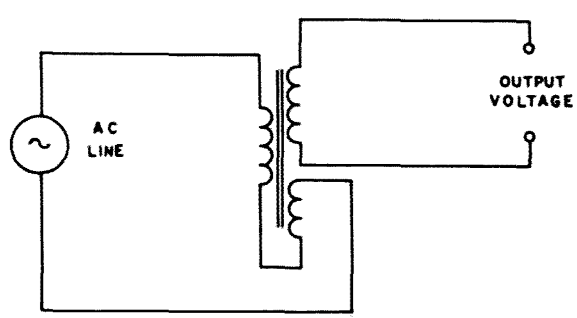

Fig. 2. The "Series-Aiding/Series-Opposing" system.

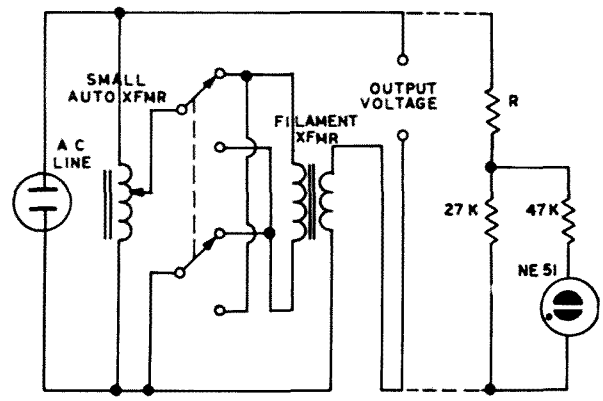

Fig. 4. Variable "Boost/Buck" system with neon bulb indicator. Adjust R so that bulb fires at desired voltage setting.

These methods of voltage control are very desirable in cases where load requirements are variable. They are much preferable to a series dropping resistor since, not only can they adjust up or down, they consume very little real power and only slightly affect voltage regulation.

Solid State Monitoring

Or . . . Here's Looking at You!

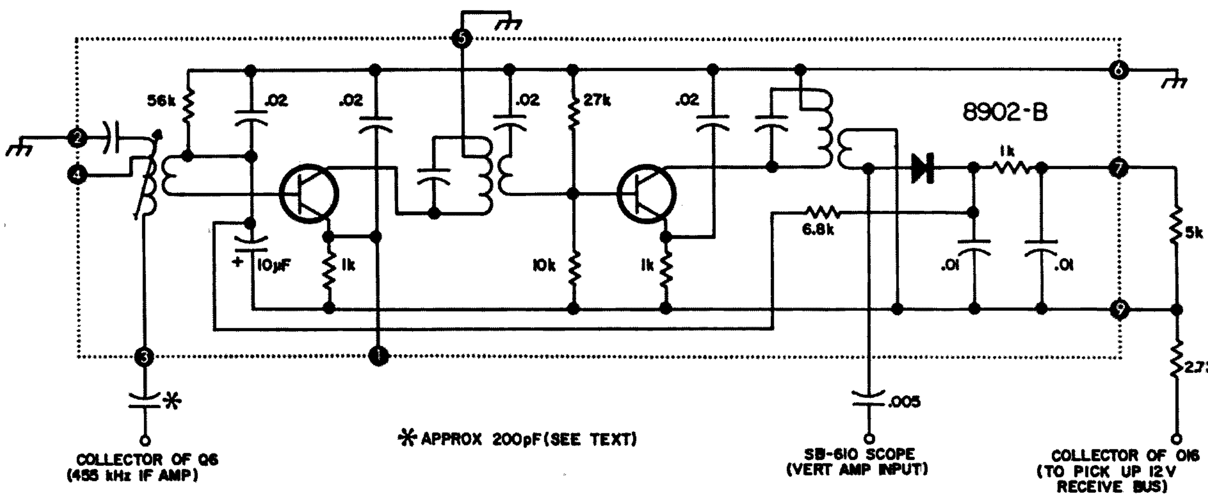

Fig. 1. The pre-wired circuit of The module.

The Heathkit Model SB-610 Monitor Scope is a convenient instrument for use with an amateur radio station to monitor "on-the-air" signals. It can also be used to monitor radio signals from other stations when used in conjunction with a receiver . . . or so says the Heath instrument manual. And the statement is certainly true; also, as easily accomplished as the manual indicates when the application is to a vacuum tube receiver's *if* strip. Try it with a solid state receiver or transceiver, and the cheese gets a little more binding, as they say!

Conventionally, receiver monitoring connections are made to either the grid or plate circuit of the last *if* stage in the receiver, using the smallest value of coupling capacitor that will give adequate pattern height. In this manner a portion of the signal is sampled and coupled through the vertical input jack of the scope to the vertical amplifier. In the cost of the SB-610 this is a vacuum tube stage employing a 6EW6. The input resistance is 100k ohms.

When the application is to a transistorized *if* stage with its lower signal level and lower impedance, the resultant picture on the scope is totally unsatisfactory. If the attempted pick up is at 455 kHz *if*, a very simple and inexpensive solution lies at hand . . . a tiny transistorized *if* module known as the 8902-B, put out by the Miller coil people. For only $3.75 this little gem will provide 55 dB gain. Bandwidth is 8kHz at 6 dB; dc requirements only 2 mils at 6 volts.

With various manufacturers hinting at new solid state receivers or transceivers on the horizon, the 8902-B may be a very handy gadget to know about. Right now any owner of an SBE 34 or 33 transceiver who has ever attempted to monitor received signals on an SB-610 has quickly found out it just won't work . . . at least, not without modification. But the Miller 8902-B module provides a made to order solution.

Fig. I illustrates the pre-wired circuit of the module and a typical application between a transistorized *if* stage and the Heath Monitor Scope, using the SB-34 as an example. The small size of the 8902-B lends itself beautifully to mounting under the circuit board at the left rear corner of the chassis. (See **Fig 2** for a simple method of mounting via a lightweight metal mount-

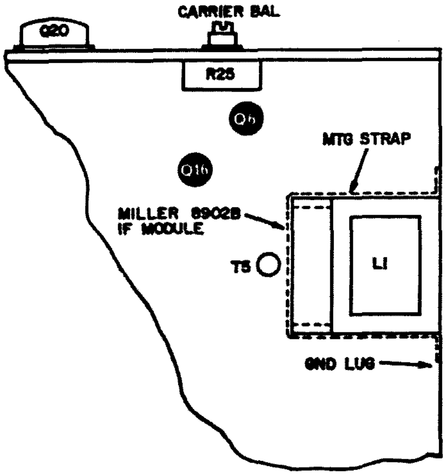

Fig. 2. Simple Mounting Method.

ing strap clamped under the existing screwed in mounting feet for audio choke L-1) This will place the module in colse proximity to the pick-up point for *if* input as well as for dc power.

Coupling to the receiver circuit is accomplished at a point under the circuit board where the collector of the 456 kHz *if* amplifier Q-6 is connected to the high side of the receive path input winding of 456 kHz if coupling transformer T-2. Fairly heavy coupling (200 $\mu\mu$F or so) is required if maximum picture height is desired. It is possible to obtain this however, and compenusate for the detuning eect by retuning the slug of T-2 for maximum audio signal by ear . . . on a received monitored signal . . . or maximum transmitter output on a two tone test. When you're all through make sure any retuning of T-2 has not upset the corret setting of the carrier balance pot.

Many of today's transceivers (whether solid state or not) make use of bilateral stages that must do double duty, functioning on both receive and transmit path. This must be taken into consideration when attempting to use the Heathkit Monitor Scope. A bilateral *if* stage would continue to provide a signal on transmit. This would be applied to the vertical amplifier of the SB-610, superimposing a signal on top of the energy being picked up from your own transmitter for the monitoring of your own *rf* output.

Here again the 8902-B strip provides an easy does it out when applied to any transceiver with a keyed voltage bus on receive. The solid state switching of an SBE-33 or 34 does this by providing a plus 12 volt bus from the collector of switching transistor Q-16 in the receive mode. The same point is at ground potential during transit, effectively killing the passage of a 456 kHz *if* signal through the little Miller module.

Terminal 7 of the 8902-B normally suplis audio output where required in receiver building block type applications. For the monitoring application described in this article the unit is easily modified as indicated by the *rf* output lead shown in **Fig. 2.** A new terminal is created for this lead by bringing out a small wire from the input side of the diode. This may be threaded through a small vacant hole that exists in the phenolic baseboard of the module between active terminals 7 and 9.

Go ahead . . . try it. You'll add new meaning to the words, "Here's looking at you"!

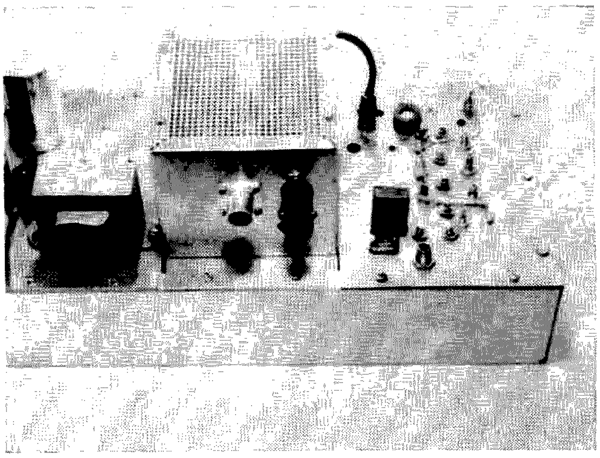
The 2 Meter Transistor Transmitter Plus One

With the present popularity of both 6M and 2M FM, the cry for more up to date equipment has been heard. Here, in part, is the answer to that cry—a transistor 2 meter FM transmitter which meets all the desired requirements: narrow band, size, efficiency, power, and most of all reliability.

The basic circuit was more or less a copy of the 250 mw transmitter circuit which appeared in the T. I. Dalcom Booklet. Unfortunately, 250 mw is not of much use, that is unless you want a walkie talkie. With the addition of the 2N3866, a power of 2.5 watts can be obtained without too much trouble. The 2.5 watts can be used to drive most any tube circuits in the 100 watts range.



The circuit

Basically the circuit is an oscillator followed by a phase modulator, 3 triplers and 4 class C amplifier stages. The power supplies are simple series regulators from a common source and a standard full wave rectifier for the high voltage.

The oscillator Q1 is a Pierce with L1 tuned to the oscillator frequency. The 33 pF capacitor from the base to ground can be variable for frequency adjustment. Some frequency pulling was noted in tuning LI.

The phase modulator is fairly straight forward. Here an ordinary AM signal is combined with a somewhat larger unmodulated carrier which is shifted in phase by 90° from the phase of the carrier in the AM signal. The resultant signal then varies in phase with the modulation. The 6.8 pF capacitor produces the required 90° phase shift while Q2 acts as the control device. The two signals are added vectorially at the collector of Q2. About 2.0 volts RMS is all that is required to give ± 5 KHz deviation at 144 MHz.

The next three stages of Q3, Q4, and Q5 are triplers which are tuned to 16 MHz, 48 MHz, and 144 MHz respectively. Q5 has an output of only a few mW which is then coupled into Q6. The output of Q6, which is a class C amplifier, is coupled by way of a 15 pF capacitor and the two 270 ohm resistors 1000 pF capacitors to Q7 and Q8. These stages have separate bias resistor and emitter resistor to help compensate for any unbalance in the dc and beta between the two units. The output here is around 250 mW to 300 mW which is coupled through the 25 pF variable capacitor to the base of the 2N3866. The 2N3866 is tuned by way of the 30 pF variable, L7, the six inches of RG-58 and L 8.

The final is a 6146 which like the other stages is operated class C. Neutralization is accomplished by use of the modified Z235. Series tuned circuits are used in the grid and the plate circuits for maximum efficiency. The output is around 35 watts with 400 volts on the plate.

The power supply shown in **Fig. 2** for the transistor stage is full wave bridge and a simple series regulator using surplus 2N1050's or any other NPN med. power transistor. The plus 28 volts supply used

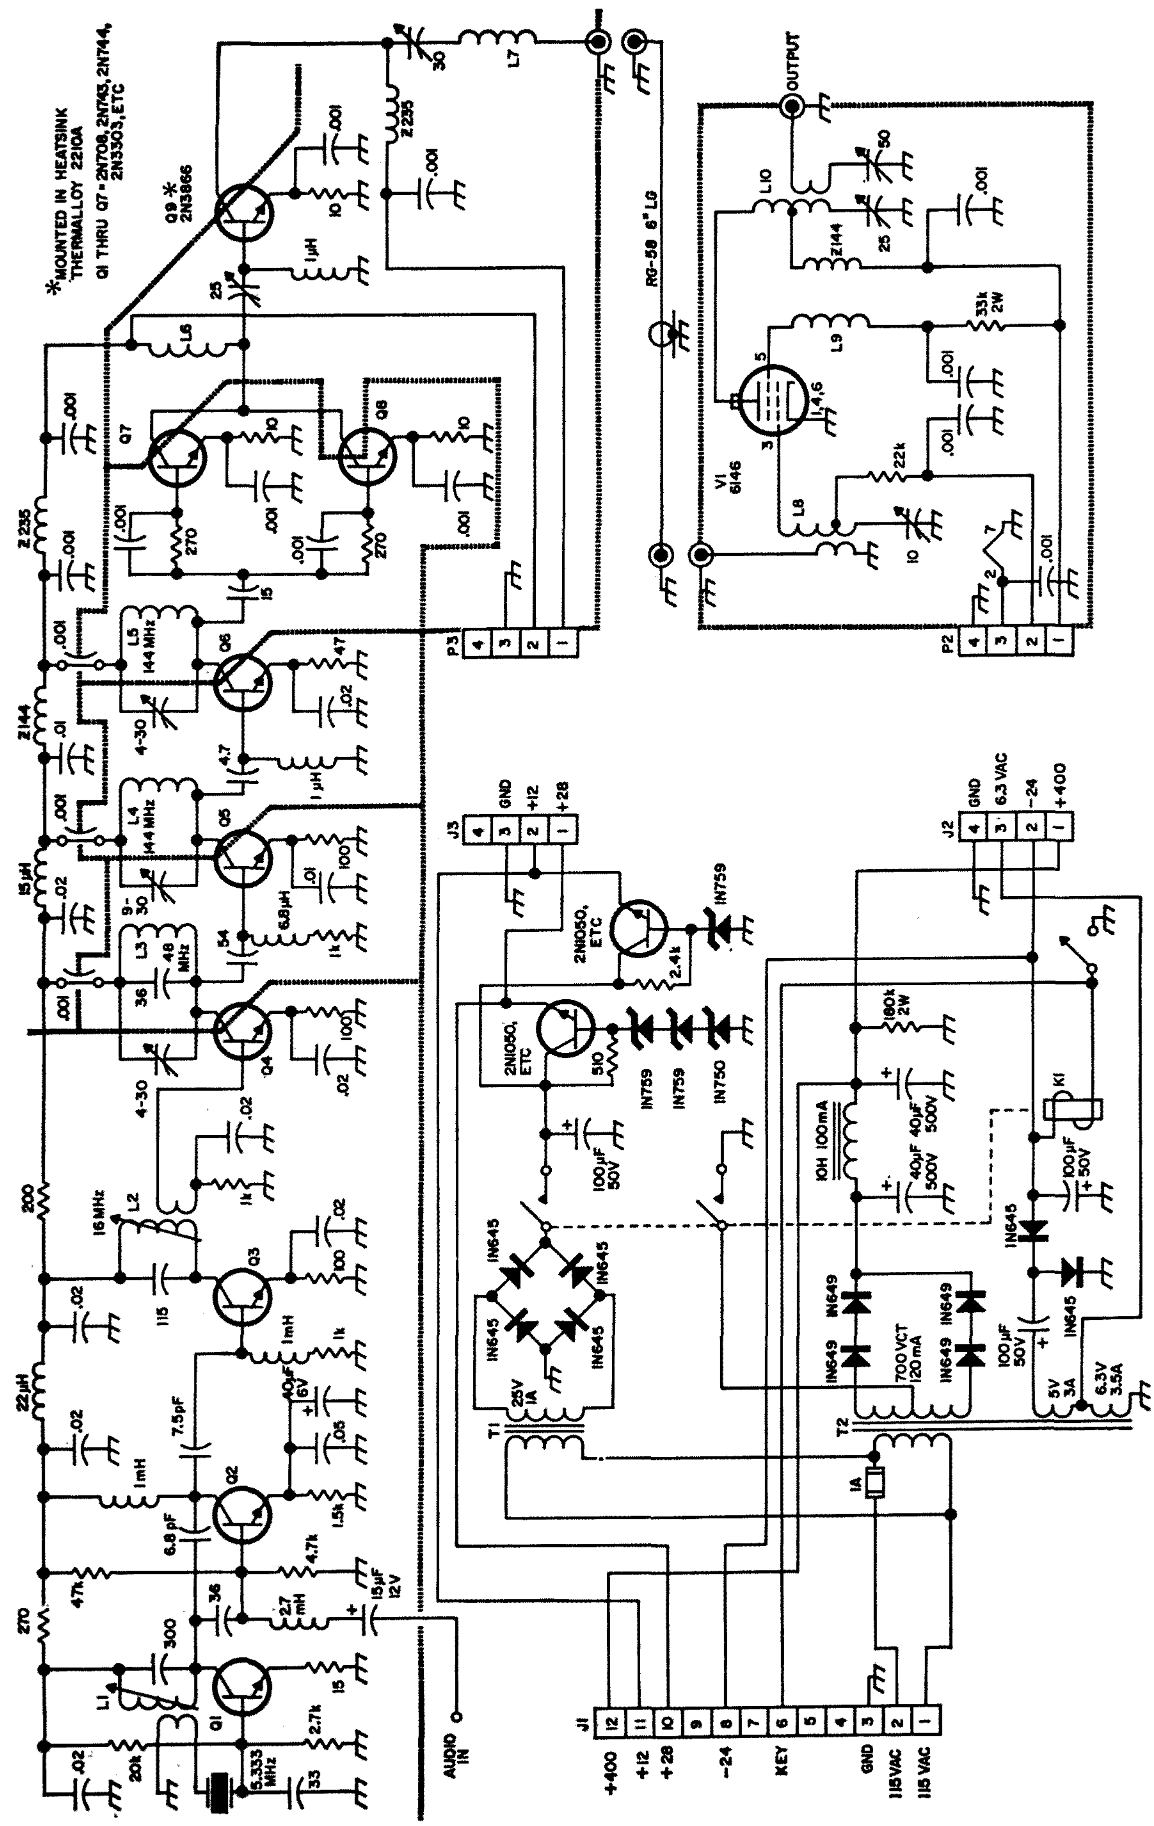


Fig. 1. Schematic diagram for the "Two meter transmitter plus one" with power supply for the transistor stage.

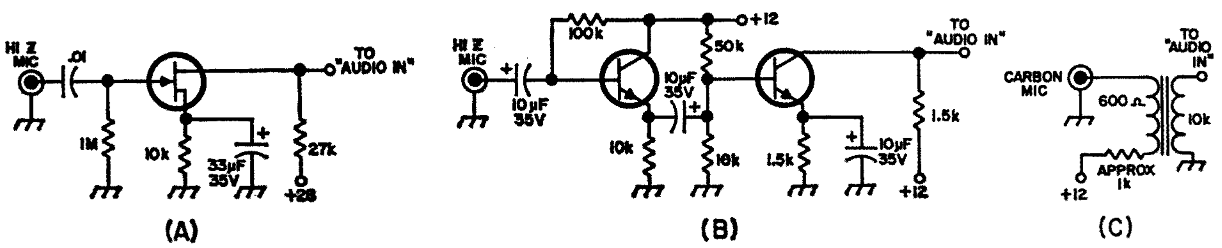

Fig. 2. Three audio preamp methods depending on the type of mike used. C is for a carbon mike, and either A or B may be used for a crystal mike.

three zeners in series for a reference but one 28 volt zener could be used. The output voltage is: zener voltage–0.6 volt. The supply for the 6146 is a standard full wave with a π filter using two 40 mfd capacitors and a 10 Henry choke. The relay voltage and the bias is obtained putting the 5 and 6 volt winding on the transformer and half wave voltage doubler in series. The fixed bias is not really high enough to hold the tube but is better than none at all. The relay K1 is used to key both the high voltage and low voltage to the transmitter.

Construction

As can be seen in the photo, no effort was made to make the transmitter in any way compact. In fact, as a general rule, the layout has quite a bit of room. The transmitter exciter is constructed on a 5 x 7 inch sheet of brass. The reason for using brass is mainly because it is easy to work with in mounting components and in making the shields. Each stage, with the exception of the oscillator, phase modulator, and the first tripler, is constructed in its own compartment. The use of ¼ watt resistor, miniature chokes, and tantalum capacitor make the construction fairly roomy.

As a general rule, no parts are critical, except in the last few stages and here only the chokes and the coupling capacitor values, but I guess that doesn't leave much! The shields are used not only as shields but also to give locations to make *good short ground* connectons. Johnson miniature variables capacitors (160-130) were used throughout except in the base and collector of Q9. Here the base and collector capacitors are midget mica trimmers (ARCO 422 40 pF to 4 pF). The output is coupled by way of a six inch piece of RG-58. Here, and only here, is the only critical point in the construction of the unit. If the coax is longer, the ARCO Trimmer in the collector of Q9 may have to be a bit larger or L7 smaller. If the final is not going to be used, the circuit shown in **Fig. 4** can be used to match a 50 ohm load. As stated before the 33 pF capacitor from the base of Q1 to ground can be variable so that the frequency can be moved somewhat. The audio is fed into the transmitter by way of a phone jack. There is no audio preamp shown on the circuit in **Fig. 1** because it was unknown what type of mike would be used. There are three methods shown in **Fig. 2A, B,** and **C** any of which will work equally well. As to the transistors used, the 2N708 were used here, but others were tried and worked about as well. The 2N708 can be bought surplus for 2/$1 from Poly Paks or new for only $1.32. The "silect" version of the 2N708 is the TIS45 which sells for around $.60 new. The best transistor tried was the 2N2369 costing $2.40.

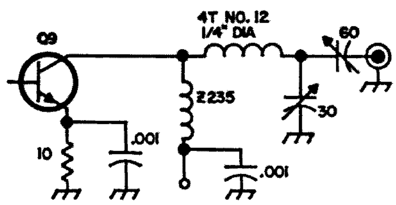

Fig. 3. If the final is not going to be used, this circuit can be used to match a 50 ohm load.

But the "silect" TIS48 costs only $.64. All things being equal the 2N708/TIS45 seems to be the best for my money. The 2N3866 is made by RCA and, to the best of my knowledge, it can not be bought surplus but is only $5.00 new. As for the transistors used in the audio preamplifier in **Fig. 3B** most any NPN would work with little or no difference at all. The FET amplifier in **Fig. 3A** has some advantage and may be preferred, here again most of the bargain FET's will work fine.

The 6146 final is constructed on a 4 x 7 inch plate and the 6146 is enclosed in a 4 x 4 inch box. The capacitor used in the

grid circuit is a Johnson Miniature (160-104). The grid coil is series tuned with the link tightly wound over the grid coil. The plate circuit is also tuned with the one turn link in the center of the coil. The transistor exciter and the 6146 final both have 4 pin male Jones connectors mounted on them so each can be removed with ease.

The power supply is mounted on an 8 x 7 inch plate. The low voltage regulator is constructed on a 3 x 2 inch piece of Vector Board. The transistor used in the low voltage regulator is any NPN medium power transistor with collector to emitter breakdown voltage of 50 volts or more. A 2N1050 was used here but any of the 2N1048, 49, 50 can be bought for a dollar or so surplus. The three units are mounted on a 7 x 17 inch chassis and a 12 pin male Jones connector is used for voltage output and keying.

Tune up

With the use of a GDO and rf indicator, such as a wattmeter, or wavemeter, the tune up is pretty simple. *Never operate the transistor exciter without a load.* If it is operated without a load the 2N3866 will be damaged. First tune L1 until the oscillator starts and shows maximum output on a wavemeter or a receiver. Next tune L2 through L9 for max rf output into the wattmeter or load. These will have to be repeaked a couple of times. The bias to the 6146 can be *removed* and a 0-5 mA meter can be used from the 22K resistor to ground to indicate grid current. With all stages peaked the grid current should be around 2.5 to 3.0 mA. The plate current should be around 150 mA at 400 volts. The screen voltage should be approximately 190 volts. The 28 volt current is around 125 mA; the 12 volt current is around 100 mA. The output was measured to be 36 watts but will vary somewhat. No provisions were made for an audio preamplifier. If a carbon mike is used, use **Fig 3C**; and **Fig. 3A** or **B** for a crystal or ceramic mike. The unit here is being used on 143.950 MHz MARS.

. . . K5WOR

The Yasme World-Wide DX-peditions

The YASME Foundation
P.O. Box 2025
Castro Valley, California

YASME II, symbolically displaying "DX - 73" on its main sail.

The YASME World-Wide DX-peditions have given many a ham his first contact with a rare country during the last decade and a half of amateur radio. To some amateurs YASME means a ship; to others it stands for a mysterious group of rich amateurs; but to the majority of the amateurs of the world, it stands for DX. Everyone who has had anything to do with YASME has been interested in DX—that special activity within the wide scope of amateur radio which consists basically of holding two-way communication with as many different "countries" as possible. At this time, the top DX amateurs of the world have held two-way communication with some 345 different such countries. Some of the areas thus classified as countries consist of remote uninhabited islands and reefs; others are small countries with only one or two radio amateurs. A DX-pedition to such areas is the only way of permitting large numbers of hams to contact them. In addition, the DX-pedition serves the useful purpose of increasing interest and understanding of amateur radio in such remote areas and establishes approved licensing procedures.

From the beginning of ham radio, some radio amateur or group of amateurs have traveled to remote places specifically to set up a radio station so that other hams would have their first contact with that place. Until 1954, however, these trips or "DX-peditions" consisted of hams who made these trips for a weekend or at the most for a fairly limited period of time. The YASME DX-peditions are the first DX-peditions in the world to make such trips on a regular, continuing basis.

In 1954, a young Englishman, Danny Weil, built a small sailing boat in which he hoped to sail around the world. He named his boat "YASME" from a Japanese word meaning good luck. He had no previous sailing experience. He was not a radio amateur. He had only a small boat and a burning desire to conquer the world by sailing around it. After many difficulties, he finally sailed into St. Thomas, Virgin Islands, where he met Dick Spenceley, KV4AA. Dick talked Danny into becoming a ham and suggested to Danny that he go on a world-wide DX-pedition in his small boat and, at each rare spot visited, Danny go ashore and operate his amateur station. This is just what Danny did for the next nine years. All told,

he worked from 27 rare countries. During that period, Danny wrecked YASME I and YASME II and had innumerable exciting experiences—many of which he was lucky to come out of alive.

Danny married in 1960 and after a relatively short period of sailing together, Danny's wife told him that he must choose the DX-pedition or her. Danny chose married life and stopped his travels. Danny wrote a 1,000,000-word book on his many hundreds of thrilling incidents such as the following, written by Danny describing the disaster of YASME II which occurred immediately after he departed from St. Vincent Islands where he had operated around the clock for several days as VP2SW.

"The first grinding crash awoke me instantly. Massive seas broke over the stern, sweeping into the cockpit. For seconds nothing could be seen as the spray blinded me. The grinding and crashing of YASME on solid rock left me under no illusions as to what had happened. Jumping out of the cockpit, I threw the engine astern, opening the throttle wide. A mad rush along the decks to release the sails. As they tumbled onto the deck, I dashed back to the cockpit.

The wind was dead astern, forcing YASME further and further onto the rocks. For seconds she would be afloat; then would come the heartrending crash as the mountainous seas picked her up and crashed her down on the unyielding rocks. How long she would accept this treatment was doubtful. I cast an anxious eye below, but saw no signs of water. Suspecting the worst, I stuck the engine bilge pump on, hoping I wouldn't need it.

The moon, where it had so recently shown peace and magnificence, now showed desolation and horror. Vicious black rocks appeared to surround YASME, as she founght for her life. Dead ahead rose a sheer cliff towering into the sky, acting as sentinel to its myrmidons of small fry. For those brief seconds I thought I had landed into a nightmare.

YASME trembled as the spinning propeller fought with the sea and wind to drag her clear. The interminable crashing and grating as nature strove to destroy her almost drove me insane. All my hopes were tied up in the engine.

Danny Weil operated from G7DW/mm, VP2VB, KZ5WD, FO8AN, VR1B, VK9TW, VR4AA, CR1OAB, YVØAB, VP2KF, VP2AY, VP2MX, VP2KFA, VP2DW, VP2LW, VP2SW, VP2GDW, VP4DW, VP7VB, VP5VB, HKØAA, HC8VB, ZK1BY, ZM6AW, VR2EO, FW8DW.

I kept looking at the rocks alongside. With each rise and fall of the seas, YASME moved an infinitesimal amount astern. Could it be possible she would get off under her own power? My body dripped sweat. I trembled like a leaf as I stood at the wheel leaning astern as though that alone would assist the creaming engine.

The first rock slid out of sight into the seething spray. For those few moments, my hopes rose. She was coming off slowly but surely. Something was amiss. An undercurrent of fear pushed itself up into my feelings of elation. I glanced quickly astern. A mountainous sea was roaring in. Its high breaking crest appeared as jagged white teeth as it swept in to engulf YASME in its maw. Petrified with fear, I gripped the steering wheel, unable to take my eyes from this monster.

Suddenly it struck. YASME rose into the air as though she were a matchbox. As it receded, she came down with her thirty tons dead weight. The wheel jerked itself from my hand. A demoniacal scream came from below as the gear box tore itself apart; then, the engine stopped.

The rudder had been smashed and jammed the propeller. A deathly silence pervaded, broken only by the breaking seas as YASME was swept back onto the rocks. Without power or steerage, she was helpless and I knew her time was limited.

With a superhuman effort, I threw the dinghy over the side. I wanted to get a

rope and anchor out astern to stop her slewing around broadside. As the dinghy struck the water, it was immediately swamped. Attempts to bail it out were futile. Several times I attempted to get into it, but the seas swept it from me. Within a few minutes, it started to fall apart, then it was gone. Only the painter tied to the rail and a small piece of timber hanging from the end proved there was actually a dinghy there at one time. As the oars floated away in the surf, my hopes vanished with them.

I ran below and fired up the rig. I had done my best to save YASME and now it was time to save me. Hanging onto the lurching cabin door, I anxiously awaited the warm-up period . . . . the seconds seemed like hours. It was tuned on 7 MHz and the band was wide open. I snatched up the mike and almost passed out. The entire rig was alive with 110 volts and I was standing in a foot of water. YASME was holed.

I had a choice. Drowning or electrocution. YASME was taking water fast. I stood there fascinated. I could hear many of my friends talking. Any one of them could have organized aid in a few seconds. The transmitter was working and I couldn't even switch it on. What an ironical position to be in!

I hated the thought, but had to accept the fact that YASME was finished. I cursed myself for being all sorts of a fool,

Dick McKercher, WØMLY, operated from WØMLY/TJ8, /TL8, /TN8, /TZ8, /TR8, TY2MY, 5V4MY.

Lloyd Colvin, W6KG, and Iris Colvin, W6DOD, operated from KG6SZ, W6KG/KG6, KC6SZ, KG6SZ/KC6, KX6SZ, VR1Z, GD5ACH/W6KG, GD5ACI/WB6QEP, GC5ACI/WB6QEP, GC5ACH/W6KG, ZB2AX, CT3AU, CT2YA, 6W8CD, 5T5KG, ZD3I, 9L1KG, 5L2KG, TY2KG, 5V1KG, 9G1KG, TU2CA. (photo by EL2NA).

but realized that recriminations wouldn't help. I had to act. I had to do something . . . but what?

I clambered out on deck and watched YASME being forced high onto the rocks. Every crash bit deep into my body like a knife being inserted and twisted. I wanted to scream and pray to God. I wanted to jump overboard and pull her off with my bare hands. To stand there and do nothing drove me frantic and made me feel life just wasn't worth living. I thought of all the work, worry and effort that had made the expedition. All of it wasted through my utter stupidity.

I was ready to give up. It seemed pointless to save even a tube. Without YASME, I was finished, and yet, it seemed so utterly crazy to let all that gear be lost. The old brain box started clicking into high gear, and I thought hard and fast. Moving along the lurching deck to the bow, it appeared I could get ashore with slight difficulty. There were many large rocks partially covered which might be used as stepping stones to the beach. I swung

over the bow, my feet fumbling for a foothold. With the jerking and swaying of the boat, coupled with surging seas, it proved an impossible task. I tried to pull myself up. My body hanging full length was too heavy. My strength was gone. I had little alternative but to drop into the water and hope for the best. It was a rough decision to make but there was no choice. With a prayer on my lips, I let go. I tried to time the drop to coincide with a receding sea, but nature played one of her dirty tricks on me and a double wave came in when it should have been going out and picked me up like a matchstick. For a few seconds, I was completely submerged as I rolled in with the wave. I expected to feel the cruel bite of the rocks any moment and knew my chances were 99 to 1 against survival in that maelstrom of angry water. Strangely enough, I felt nothing. My head broke water and I struck out shoreward, wondering all the time if I was doing the right thing. Guess I was going to have to meet up with those rocks sometime and it may as well be now, as I was pretty weak and couldn't hold out much longer.

Seems we all get that little extra strength in times of need. I found myself a big rock and, swimming to its lea, managed to climb its rough sides with little damage other than minor abrasions. From this vantage point, I was able to make a complete survey. The actual shore was twenty feet from me. Timing my dive right, I did reach the shore O.K. My prayers were surely answered, and I thanked God to be on dry land and safe."

To help obtain funds to get another boat and new radio equipment for Danny after experiences such as just described, a group of influential hams interested in DX founded the YASME FOUNDATION in 1960. This is a nonprofit foundation and qualifies as an organization to which tax-deductable donations may be made.

In 1962 the YASME Foundation also sponsored a highly successful DX-pedition by Dick McKercher, WØMLY, to seven rare countries in Africa.

The YASME DX-peditions so far mentioned were conducted on the basis that amateurs worked were urged to make a small contribution with their QSLs to help defray a portion of the costs. This was, and still is, a highly controversial subject. Some amateurs feel no one in amateur radio should ever send money to help a DX-pedition, while others feel a small donation is more than justified. In any case, the Directors of YASME found that in order to keep DX-peditions such as Danny Weil's going they had to put a lot of their own money into the Foundation. This became a discouraging and expensive procedure and the Directors decided to let the YASME Foundation become dormant unless someone wanted to pay their own way on a DX-pedition and let the YASME Foundation help in other ways than direct financial responsibility.

In 1965, Lloyd Colvin, W6KG, and Iris Colvin, W6DOD, retired from business and went on a sustained DX-pedition under sponsorship of the YASME Foundation. All travel and equipment expenses were paid by Lloyd and Iris, with the YASME Foundation taking care of QSLing and publicity.

During 1965, 1966, and 1967, Lloyd and Iris traveled around the world, primarily by commercial aircraft, and worked from 22 rare countries.

Lloyd and Iris, after some two and one-half years of continuous travel, have decided to stop doing it on a full-time basis. They may, however, make occasional short-period DX-peditions under YASME sponsorship.

During the DX-peditions made by Lloyd and Iris, some donations have been received by the YASME Foundation. About half of the money so received has been used on QSLing expenses. The balance is held by the YASME Foundation which wishes to announce to the radio amateurs of the world that their donations will be spent for equipment in accordance with the following resolution passed by the Board of Directors of YASME:

"IT IS RESOLVED that the Treasurer be authorized to purchase radio equipment from cash on hand and that said equipment will be loaned to amateurs approved by the Foundation who are going on DX-peditions, and who agree that the confirmation cards, or QSLs issued for contacts with said DX-peditions will give printed acknowledgment to YASME FOUNDATION for supplying the equipment used, and further providing that said amateurs using said equipment will first sign a written agreement to return

said equipment immediately upon completion of the DX-pedition in good condition, reasonable wear and tear excepted."

Anyone desiring to use such equipment for a DX-pedition, under the sponsorship of the YASME Foundation, is invited to write to the Foundation.

This article would not be complete without paying tribute to the Directors of the YASME Foundation, most of whom have been associated with it since the early DX-peditions made by Danny Weil, and all of whom have devoted much time, energy and money to further DX. The present Directors are Danny Weil (now a U.S. citizen, living in Texas); Bob Vallio, W6RGG (QSL manager and the hardest working man in the organization); Tom Taermina, WA5LES (publicity director and Editor of the West Gulf DX Bulletin); Ed Peck, W6LDD; Charles Biddle, W6GN; Golden Fuller, W8EWS; Hal Sears, K5JLQ; Jack Drudge-Coates, G2DC; and Dick Spenceley, KV4AA.

SAMS Books

People working in the electronics field appreciate its very great complexity, and usually spend some time learning more about the fundamentals and the technology. And the field is changing all the time, so that what is basic one year may be outdated the next.

Good study material is always valuable and may serve as a very useful advancement tool, also. Here is an example. Sams has just published a four volume set of books on transistor fundamentals. Their set covers the whole range from basic ideas (which should be reviewed, and not too rarely), through special circuits.

The four books are titled *Basic Semiconductors and Circuit Principles, Basic Transistor Circuits, Electronic Equipment Circuits,* and finally *Digital and Special Circuits.* This arrangement is something like a large novel in four volumes, in which you must start at the beginning to understand what it's all about.

Look for these and other SAMS books in your local amateur radio or other electronics oriented store. Or you can get them direct from SAMS at $4.50 each or $15.95 for the set.

The LC Power Reducer

John Schultz W2EEY/1
40 Rossie St.
Mystic, Conn. 06355

Reducing the power output of a transmitter or exciter while still having it work into the same load conditions as under full power output is usually accomplished by means of relatively expensive resistor T networks. This article presents a simple LC network which will much more economically accomplish the same purpose. Its operation has been proved by extensive usage in the broadcast field for high-power transmitters.

There are many reasons why one may wish to reduce the power output of a transmitter or exciter: for test purposes, to provide the proper drive level for high-power linears, to reduce QRM by using only the power required for a QSO, etc. The circuit described in this article affords a simple method to provide almost any desired degree of power reduction on any single amateur band. Perhaps the most outstanding feature of the circuit is that it uses only one resistor—a 50 ohm unit (for 50 ohm coaxial lines) which may, in fact, be the regular station dummy load. Therefore, no special high-wattage, non-inductive resistors of odd values are necessary as with conventional resistor-network power reducers. Not only are such resistors generally expensive and difficult to find, but they allow only one fixed value of power reduction. Certainly, they represent a very expensive item when a power reducer is desired only for occasional test purposes.

The circuit described in this article is certainly not new and no claims are made in that direction. Broadcasters will recognize the circuit as one which has frequently been used to reduce the output of high-power broadcast transmitters. It has not, however, received any usage by radio amateurs, probably because it was developed before the advent of high-gain, high-power linears required many amateurs to reduce the output and load conditions of the final stage as though the exciter were operating at full power output.

Basic Circuit

Fig. 1 shows the basic circuit of the power reducer. The two reactances form a power divider and the ratio of their values determines how much of the input power flows into the dummy load and how much power flows into the output load. When the dummy load and the output load are both 50 ohms, the input impedance will remain a constant 50 ohms regardless of which power reduction ratio the reactive elements are set up to accomplish. If the circuit is redrawn, as in **Fig. 2**, its operation may be clearer. At any particular frequency, the circuit is that of a simple voltage divider network. Note that since both the dummy load and actual load resistances are equal, they can actually be interchanged. This feature will be found of value, as explained later, when reactance values which are also physically possible must be determined.

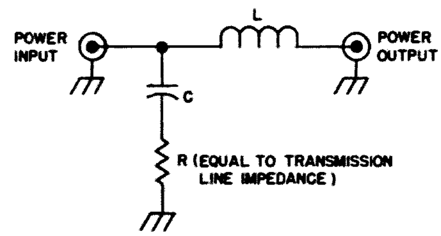

Fig. 1 Basic circuit of the LC power reducer.

Circuit Value Calculation

The value of the dummy load resistor is simply equal to the value of the transmission line impedance being used, usually 50 or 70 ohms. The power rating of the resistor is simply determined by the power reduction the whole circuit is desgined to achieve. If the output of a 500 watt transmitter is desired to be reduced to 50 watts, for example, the dummy load resistor must, naturally, handle the surplus 450 watts.

The value of the reactive elements is determined from the following formulae (substitute 70 for the 50 values shown if a 70 ohm coaxial system is used instead of a 50 ohm system).

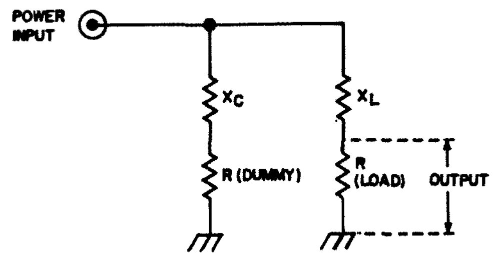

Fig. 2 The equivalent of Fig. 1 at any particular frequency is a simple divider network. Both resistances are the same value.

X (in series with dummy load)

$$= \frac{50}{\sqrt{\frac{P_{IN}}{P_{OUT}}}} \text{ ohms}$$

X (in series with output load)

$$= \sqrt{\frac{P_{IN}}{P_{OUT}}} \text{ x } 50 \text{ ohms}$$

Note that no signs are shown for the reactive values. The only criteria is that they be of opposite values but which one is capacitive and which is inductive is not theoretically important. An example should make this point clear.

Suppose it is desired to reduce the output of a transmitter from 500 to 50 watts, operating at 4 MHz and using 50 ohm transmission line. Then,

$$\text{X (dummy)} = \frac{50}{\sqrt{\frac{500}{50}}} = 15 \text{ ohms}$$

$$\text{X (output)} = \sqrt{\frac{500}{50}} \text{ x } 50 = 165 \text{ ohms}$$

If it is desired to use a capacitive reactance in the dummy load leg, one looks up from a handbook graph the value of capacitance producing 15 ohms at 4 MHz (or calculated from the formula ($\text{pF} = \frac{1590 \text{ x } 10^8}{\text{f(Mc) X}}$) which is 3,000 pF. The output leg must then contain an inductive reactance of 165 ohms at 4 MHz which is 5.4 μH.

$$\text{L}\mu\text{H} = \frac{159000\text{X}}{\text{f(MHz)}}).$$

If one were to reverse the reactances, their values have to be determined again (the actual capacitor and inductor cannot be simply exchanged). An inductor in the dummy load leg would have 15 ohms reactance and a value of 0.6 μH. The capacitor in the output leg would have 165 ohms reactance and a value of 250 pF. The two circuits which result from these calculations and which perform exactly the same degree of power reduction are shown in **Fig. 3.**

If the reader wants to check the calculation of the reactive values, another example would be the reduction of the power output of a 100 watt transmitter to 10 watts at 30 MHz. If a capacitor is used in the dummy load leg and an inductor in the output leg, the circuit values are 360 pF and 0.9 μH. If an inductor is used in the dummy load leg and a capacitor in the output leg, the values are .08 μH and 30 pF.

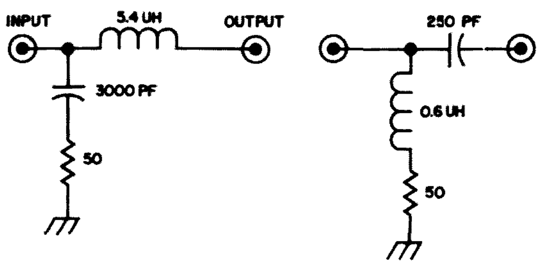

Fig. 3 Both circuits shown achieve a 10 to 1 power reduction ratio at 4 MHz. The method of determining the inductor and capacitor values is explained in the text.

Construction

Before a unit is constructed the reactive values necessary for both circuit options should be calculated in order to check which option fits parts on hand or is easier or cheaper to construct. For instance, if using new parts, the circuit of **Fig. 3(B)** would certainly be less expensive than that of **Fig. 3(A).** In the 30 MHz example given, the circuit option which produced an 0.9μH inductor would certainly be less critical to construct than that producing an 0.08 μH inductor.

No special construction methods are necessary and the components can be enclosed in a standard minibox. If the inductor is in the output leg, its wire size need only be appropriate for the amount of current produced by the output power in a 50 ohm line and results in a relatively inexpensive

inductor if a large amount of input power is being reduced to a low value. The capacitor should be a mica transmitting type and its minimum voltage rating can be determined by finding the current flowing because of the power dissipated in the leg in which it is used and then simply determining I^2Xc. Normally, the voltage rating will be quite low for even high powers but the current (rf) rating of the capacitor should also be checked with the manufacturer's rating.

Summary

The LC power reducer can be built and used in a number of versatile ways. Since it uses a standard dummy load resistor, it can be built as part of a dummy load. A tapped coil and variable or switched capacitor can be used if multi-band operation is desired. Or a variety of power reduction levels for one band, while maintaining constant transmitter loading, can be achieved using a variable inductor and capacitor. To achieve the same flexibility with purely resistor networks would require a very elaborate and expensive collection of switches and resistors indeed. . . . W2EEY

Amphenol's Color Commander Generator

Service oriented amateurs will be interested in Amphenol's new color bar generator. Priced at $139.50, it generates a set of nine assorted patterns for adjustment of centering, convergence, and other service controls of any color TV set.

Patterns consist of a single vertical or a single horizontal crossbar or the two combined; a single center-screen dot, three color bars, several horizontal and vertical patterns, and square or dot patterns for dynamic proportioning and convergence adjustments.

The Amphenol Color Commander contains an internal rf generator whose output is applied to the receiver's antenna terminals. Color sync and other circuits may be checked because the Color Commander uses a crystal oscillator with unijunction transistor countdown circuits for accuracy and stability. Operates from batteries or from an ac supply in the battery compartment.

For additional information on their Model 860 Color Commander, contact Amphenol Distributor Division, the Bunker-Ramo Corporation, 2875 South 25th Ave., Broadview, Ill. 60153.

Why Ham RTTY

James L. Turrin WA8DCE
P.O. Box 245
New Philadelphia,
Ohio 44663

The symbol "F-1" on authorized emission charts in FCC regulations may not mean much to some amateurs. To others it is an open door to an entirely different concept of communications. It signifies a technology which is challenging enough for the most learned engineer, yet basically simple enough for the greenest neophyte. This symbol "F-1", along with the symbols "A-1" and "A-2" authorizes amateur radio-teletype (commonly called RTTY) on all bands except 160 meters.

The word "Teletype" is actually the trademark of the leading manufacturer of teleprinter machines, the Teletype Corp. Over the years "teletype" has come to be a term used synonymously with "teleprinter" which is the actual descriptive name of the machine.

"Why Ham RTTY?", you ask, when we have CW, AM and SSB available to communicate with other amateurs in most countries throughout the world. The answer is simple. Amateur radio, by international agreement is designed as a service dedicated to furthering communications technology all over the world. It is a means of bringing together people from all walks of life, all races, creeds and religions who share a common interest, i.e. to communicate ideas and thoughts to each other. Amateur radio is also dedicated to furthering technical knowledge of many different means of communication by encouraging experimenting in these areas. This is commonly called "advancing the 'State of the Art'".

Amateur radio is made up of thousands of hardy individuals who are looking for a challenge or project just a little bit more difficult than the one they have just been involved in. These are your "experimenters" and "builders". These people, although not forsaking the old tried and proven ideas and modes of communication, are interested in new and different means of communicating. It is these people who look to the different areas of amateur activity such as Amateur Television. Facsimile, Slow Scan TV, FM, narrow band FM and Amateur RTTY for their enjoyment.

For many years, commercial telephone and telegraph companies have used teletype to transmit and receive printed messages from point to point in the U.S. and other countries. Teletype is a means of transmitting signals through wires from one teletype machine to another by the switching on and off of a dc voltage in a code pattern which the machine understands and converts to mechanical motion causing a type character to strike a sheet of paper thereby printing the message in directly readable form.

Amateur radio operators saw the opportunity to utilize another communication media when these machines came into use. The first problem they had to overcome was how to get the pulsing code signals from one machine to another. After trying various methods which worked crudely and only at times, these pioneers developed the process now called "Frequency Shift Keying" (FSK) or F-1 as termed by the FCC.

The FSK transmitting process is basically this: The transmitter is on the air and transmitting steadily at a given frequency called the "mark" frequency. When the desired character key on the teletype keyboard is depressed, a motor driven mechanism produces a switching off and on, in a code group assigned to the desired character, of a dc voltage. This voltage then activates an electronic unit which either directly or indirectly causes a reaction in the transmitter's frequency generating section which shifts the transmitted frequency very slightly for a period of about 22 milliseconds. It is this short period of frequency shift, when transmitted in code groups of the proper pattern, carries the teletype signal over the air. The frequency shift may be any value up to 900 Hz as allowed by FCC regulations. The most commonly used shift is 850 Hz although shifts as low as 170 Hz and 160 Hz are being used occasionally. This shifted frequency (generating the mark frequency minus 850 Hz) is called the "space" frequency.

A variation of the FSK which is authorized on high bands only (6 meters & up) is AFSK which means Audio Frequency Shift Keying. This method utilizes the constant carrier on action of either AM or FM but instead of a voice signal being transmitted, an audio tone of 2125 Hz is generated in an audio signal generator and shifted by the teletype machine 850 Hz to a tone of 2975 Hz. This audio signal is impressed upon the carrier frequency in the same manner that a normal voice signal would be transmitted. This system does not involve changing of the basic transmitting frequency as does the FSK system.

The receiving of RTTY signals requires receiving equipment of reasonable stability and selectivity. The incoming FSK signal is treated the same as a CW signal in that it is detected and changed to an audio signal by the BFO control on the receiver. The audio output to the speaker is tapped and some of this signal is fed to the RTTY converter. The converter amplifies these signals slightly and feeds the complete audio signal through two audio filters which only allow audio tones of a certain frequency to pass through them. These filters do not allow any other audio frequency to pass except the frequencies the filters are designed for. Usually these two audio frequencies are 2125 Hz and 2975 Hz. The BFO on the receiver is tuned until the steady audio tone coming from the receiver is 2975 Hz (mark freq.). This audio tone will pass through the "mark" filter. The frequency shift of 850 Hz will change the audio tone to 2125 Hz (the "space" freq.). This tone will pass through the "space" filter on the converter. These two audio tones are then amplified further and one or the other becomes the triggering pulse for an electronic switch which switches off and on the dc voltage in the proper sequence necessary to operate the teletype printing mechanism. The proper combination of off-on pulses of the dc voltage being fed to the printing unit then sets up the mechanical reaction necessary to print the proper character on the paper.

The equipment involved need not be expensive. In fact, by using an existing AM/CW transmitter (either crystal or VFO controlled) and the station receiver you already have, you can be on the air on RTTY for less than the cost of most SSB transmitters on the market today. The teletype machine itself will probably be the most expensive investment, costing anywhere from $20.00 and up, depending upon your source of supply. The RTTY converter can be either purchased commercially or home brewed from your junk box (or your buddy's) according to many schematics available today. The cost of this unit could run anywhere from $15.00 and up for a home brewed unit, to nearly $200.00 for an exotic commercially built version. The FSK unit generally must be designed and built to match whatever transmitter you are planning on using.

There are several good publications available today which carry schematics and construction details of converters, FSK units and other handy RTTY gear. These can be found listed in catalogs published by most electronic suppliers.

Ham RTTY is a service of high value in message handling and net activities. It is also a tremendously fascinating field which, as I stated before, can be challenging enough for the most experienced engineer yet basically simple enough that the newest ham can understand it.

This article was written, not to make RTTY experts of any of its readers, but, mainly to whet the readers' appetite to want to learn more about this fascinating phase of amateur radio. Amateur RTTY has its problems and frustrations just like the other modes but that is the real test of an amateur's dedication and zeal towards the goal he pursues; which is to advance the 'State of the Art'.

Panadaptor or Spectrum Analyzer

Definition

A panadaptor, or radio-frequency spectrum analyzer, is a device which provides a panoramic display of the signal distribution in a selected portion of the radio-frequency band. The display takes the form of a plot of amplitude versus frequency, usually on the screen of a cathode ray oscilloscope.

History

Little work was done in the field of panoramic presentation of radio frequency spectra during the years preceeding World War II. However, the huge amount of organized research and development work in the field of microwave radar performed as part of the war effort caused a tremendous expansion in radio measurement techniques and measuring apparatus. At the Massachusetts Institution of Technology Radiation Laboratory, spectrum analyzers of various types were developed for use as test equipment in the design of pulsed oscillators for radar transmitters.

Although this first use of the spectrum analyzer was quite far removed from ham radio, it was not long before a ham decided this would be an extraordinary way of monitoring an entire ham band at a glance. Exactly when the first spectrum analyzer was used on the ham bands is not known to the author. The Hallicrafters Company, however, produced a commercial unit shortly after the war in early 1946. This was known as their model SP-44 Skyraider Panoramic. The unit was not widely accepted and was generally termed a worthless device and soon almost forgotten. The panadaptor did not become widely known again until 1965 when Heathkit introduced their Ham-scan Model HO-13. Today the basic operation is known to most all hams and some have learned to

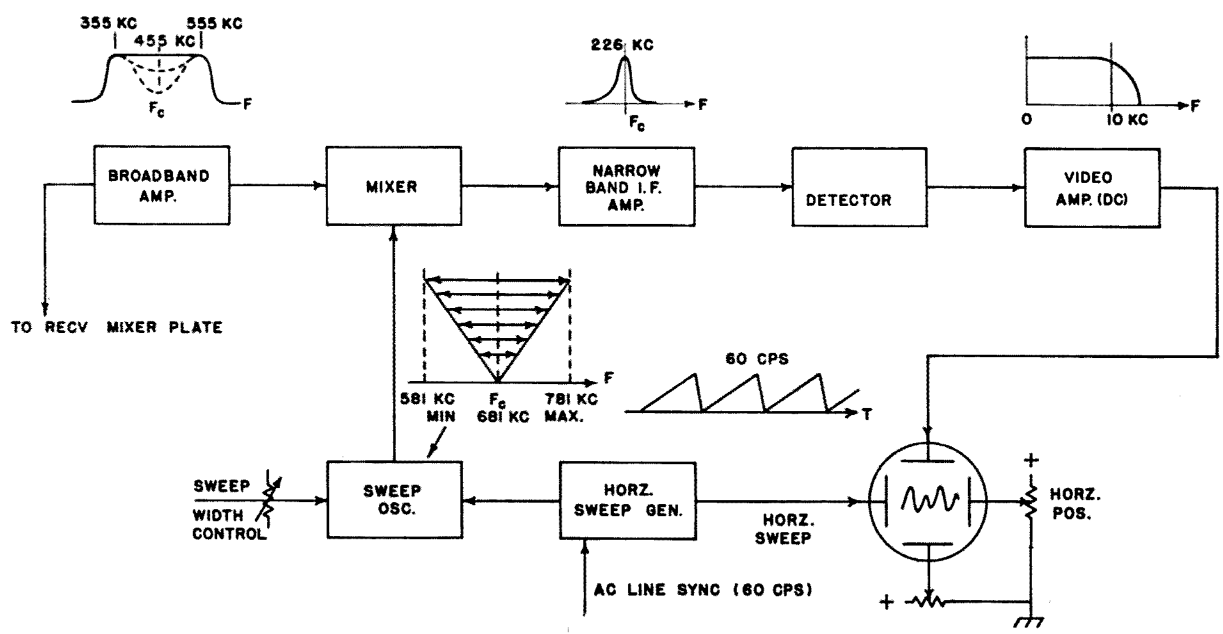

Fig. 1. Block Diagram of panadaptor spectrumanalyzer.

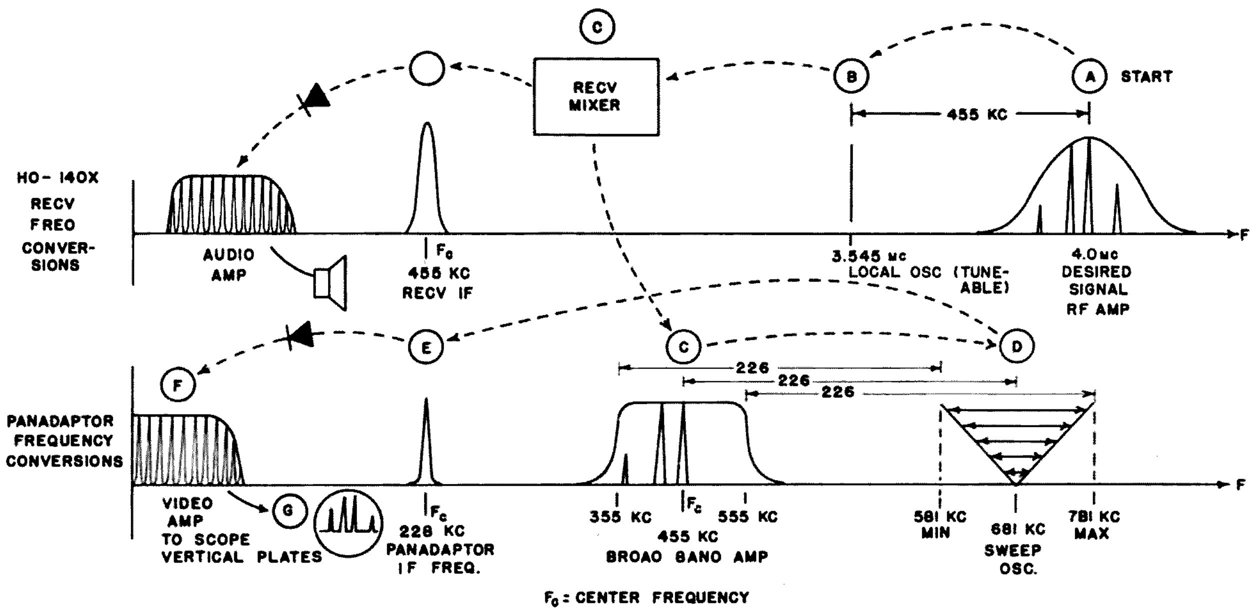

Fig. 2. Frequency conversions in a Panadaptor system.

A. Receiver rf amplifier showing broad band pass and four stations.

B. Receiver local oscillator displaced 455 kHz from desired station.

C. Here signal splits between receiver if and to panadaptor broadband input amplifier.

D. Variable sweep width FM oscillator mix with signals from broadband amplifier. Those with 226 kHz frequency difference pass on into panadaptor if amplifier.

E. Panadaptor if amplifier band with sets resolution of system.

F. if signal rectified and audio components send to scope plates.

G. Scope presentation shows stations as in A.

use it to great advantage in every day spectrum and signal analysis.

Operation

A spectrum analyzer is essentially a narrow-band superheterodyne receiver which is repeatedly swept in frequency over a selected portion of the radio-frequency band. At the same time, the horizontal deflection of the spot on a cathode ray tube moves in synchronism with the rf sweep. The vertical deflection of the spot is proportional to the output voltage of the receiver. The resultant display is a plot of amplitude versus frequency over the radio-frequency band of interest.

Fig. 1 illustrates a block diagram of a simple spectrum analyzer such as the Hallicrafters SP-44 and the Heathkit HO-13. This block diagram, of course, shows only the basic elements that are necessary to explain the operation of the analyzer. It can be seen from the block diagram, the primary deviation from a standard superheterodyne receiver is the horizontal sweep oscillator and a cathode-ray tube readout in place of the speaker. A careful study of this diagram and of the Frequency Conversions diagram (See **Fig. 2**) should illustrate basically how the panadaptor works. **Fig. 3** shows some typical wave forms which can be expected.

Uses

The panadaptor is best known for its abilities as described above, to provide a panoramic display of radio signals in a selected portion of the radio frequency spectrums. This first use is probably what caused a loss of interest in the device as one soon tires of only eavesdropping on the amateur bands. Only when you delve into the theory of the device, understand, and try to find new uses does it become useful. The following ideas are a few to which I have put mine to use:

1. Watch the stealthy spectrum pirate. He is the one who slyly tunes up on another frequency and then slides down 10 KHz to the frequency his buddies are on. You may also watch the band swoosher go by and track him to a frequency where he may finally identify himself.

2. Watch for band openings on the higher bands. With the receiver set in the

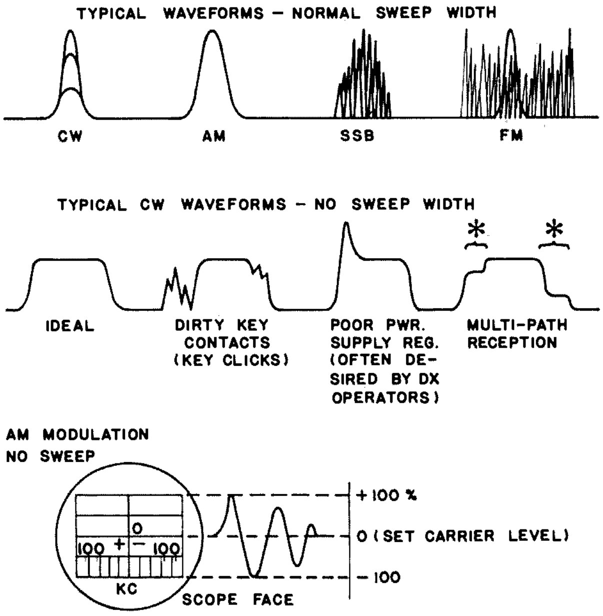

Fig. 3. Typical panadaptor wave forms.

middle of the 15, 10, or 6 meter band, watch for the signals to pop up.

3. Analyze modulation of other stations. Decrease the sweep-width to zero and you have a modulation analyzing oscilloscope. This will detect modulation percentage of AM and flat-topping of SSB.
4. Examine any mode signal (AM, CW, SSB) for spurious radiations—Splatter or parasitics have been quickly traced to the originating station with this device. (Take notice 00s.)
5. Examine keying characteristics of CW stations—Drop the sweep-width to zero and watch. (See **Fig. 3**) You must be careful on distant stations on the lower band as they are very susceptible to multipath propagation and distortion of the waveform.
6. Examine characteristics of multipath reception and radio propagation in general by using the time domain reflectometry technique. In time domain reflectometry, a sharp front long period signal is sent out and the measurements are made by the effects of the reflected signal on the amplitude of the original signal. An example is shown in **Fig. 3** of the CW multi-path reception. This technique is opposed to the pulse-echo method used in radar where a sharp pulse is transmitted and the echo is awaited. Time domain reflectometry is practical in ham radio as the pulse may easily be generated by a "bug" or "automatic keyer" and does not take up valuable radio-spectrum. I have measured the virtual height of the "E" layer by this technique.
7. Find open spots in the bands for transmitting.
8. Monitor own transmitted signal through receiver—Check for modulation and spurious radiations.
9. Zero beat WWV with the 100 KHz calibrator.— By watching the "pulsations" of the waveform on the scope, it

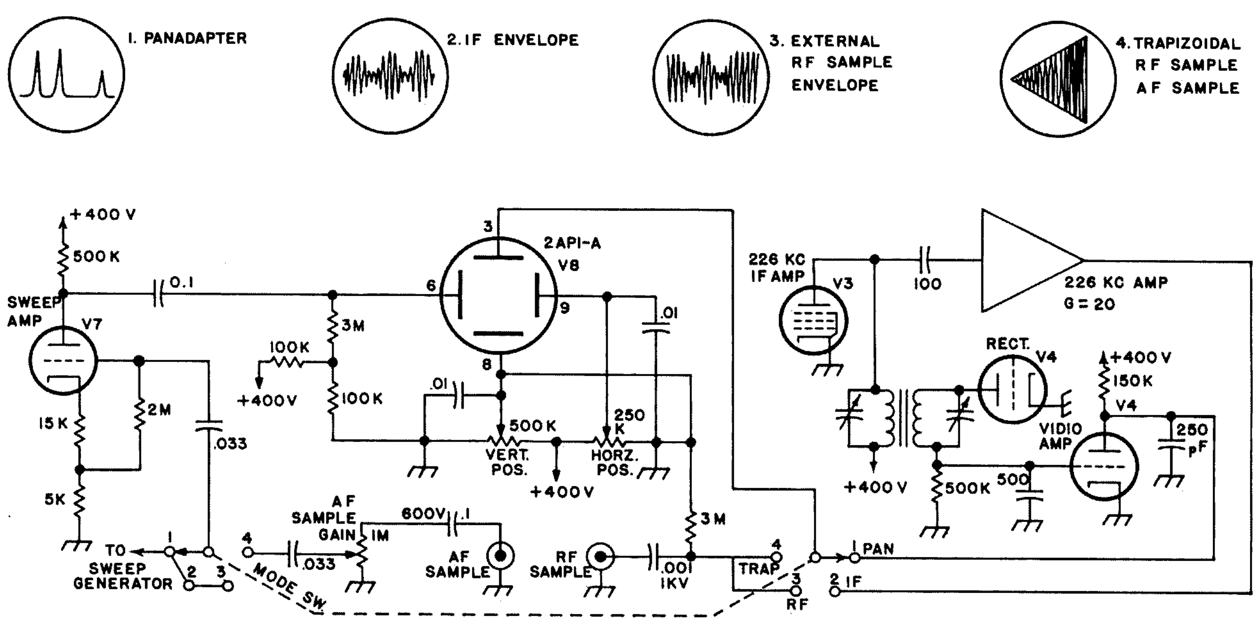

Fig. 4. C.R.T. Plate deflection circuits. Modified SP-44.

is possible to zero beat well below the audible beat. You may also check your own line frequency by watching the 600 Hz note on WWV. You'd be surprised how poor our 60 Hz line frequency is.

In addition to the nine described above, a modification to the panadaptor will add to the uses to which it may be put.

Modifications

On my Hallicrafters SP-44, I have made modifications to the circuits so the cathode-ray tube may be used for multi-purposes. A four position switch was added and the following uses were added to the panadaptor:

1. Normal panadaptor - standard uses as noted above.
2. *rf* Envelope presentation of panadaptor *if*.
3. *rf* Envelope presentation of external transmitter - A jack was added on rear apron for *rf* sample.
4. Trapezoidal pattern of external AM transmitter. A jack was added on rear apron for *af* sample. This switch position combines *rf* and *af* samples to give trapezoid pattern.

See **Fig. 4** for modifications to SP-44. These modifications were made only to the horizontal and vertical deflection plate circuits. Therefore, the modifications shown in **Fig. 4** only show those circuits driving the deflection plates. Any good handbook on ham radio and modulation techniques will describe what they can do for you.

Summary

I have found that the panadaptor is one of the most useful instruments that I have in my shack. In ham radio you normally use only one of your body senses in making contacts and that is the sound that impinges upon your ear. The panadaptor adds a second and that is sight. The ability to *see* as well as *hear* what is going on in a band adds a third dimension to amateur radio.

The "Six Net"

John J. Sury W5JSN
3013 Valerie Court
Arlington, Texas 76010

Did you ever build a receiver that has sensitivity, selectivity and stability? In most cases one may have to be sacrificed for another. Here is a receiver that has all these features. The complete receiver is constructed on a 4 x 6 x 2 inch chassis and a 4¼ x 6 x ⅛ inch panel, including the ac power supply.

The receiver is a 10 transistor superhet which includes the 2 transistors in the Miller *if* strip. The *rf* section is a common base amplifier followed by a common emitter mixer. A special variable crystal oscillator and multiplier injects a signal 455 kHz above the incoming frequency. The oscillator is an untuned common emitter crystal controlled oscillator. The capacitor in series with the crystal varies the frequency 2 to 10 kHz being multiplied depending on the type of crystal used, and its activity. An amplifier multiplier section follows the oscillator. The multiplied frequency is injected in the emitter of the mixer. The difference is amplified and detected and then is amplified by the audio amplifier.

The power supply is a voltage doubler, which is regulated by 2 2N706's (cheap kind) as reference voltage and a 2N1038 transistor. This makes a fine regulated power supply.

The majority of the parts may be purchased through your Allied Radio parts catalog except for the coil forms, which were purchased from Newark Radio. The coil forms are Camboin SPC-1 2170-3-3.

I started with the circuit boards. Use the patterns in this article, they are full scale, or try your own design. I used one side foil boards, they are cheap and less complicated in laying out circuits. Your local drug supply should have Ferric Chloride on hand in the solid form or he can get some from his supplier. Dissolve it in hot water and make it strong. I keep dissolving until the solution is almost saturated. Be careful not to spill any; it sure makes a mess. Use only plastic or glass trays for etching. I watched aluminum disappear before my eyes. I used a commercial resistant, but if not available, finger nail polish or model

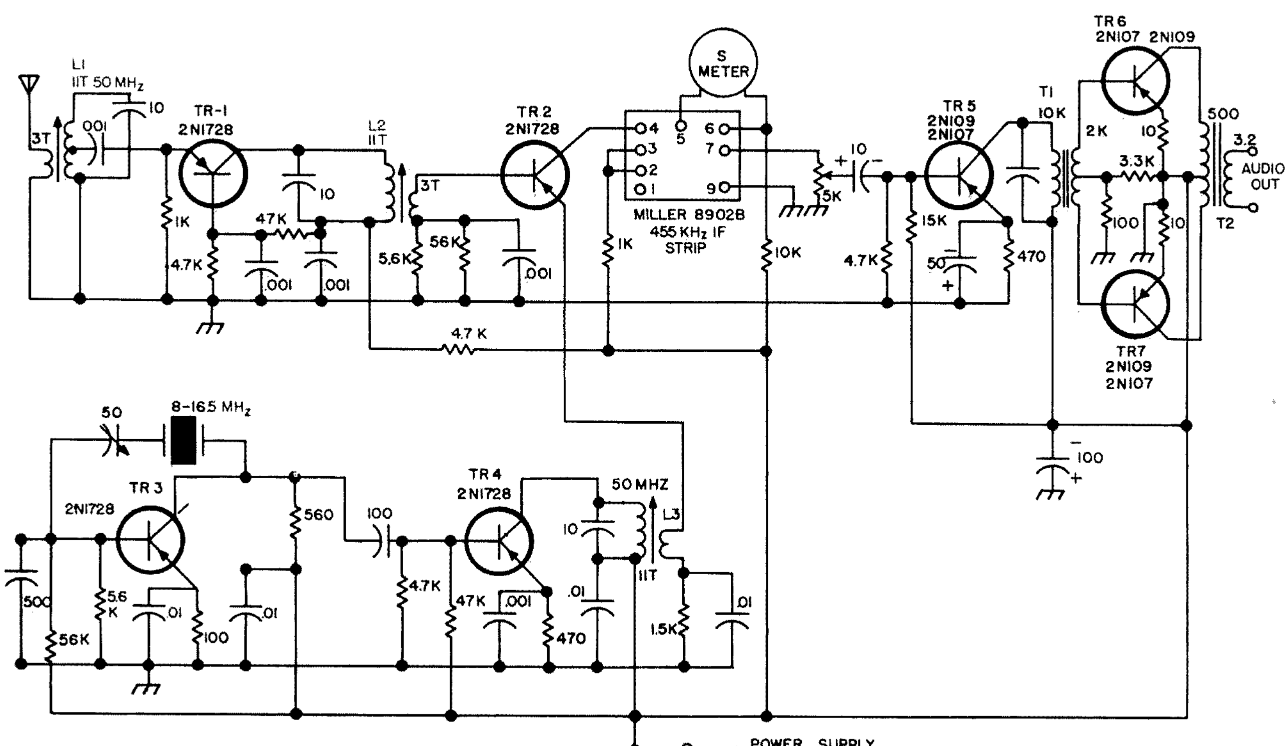

Fig. 1. Schematic for the "Six Net" receiver.

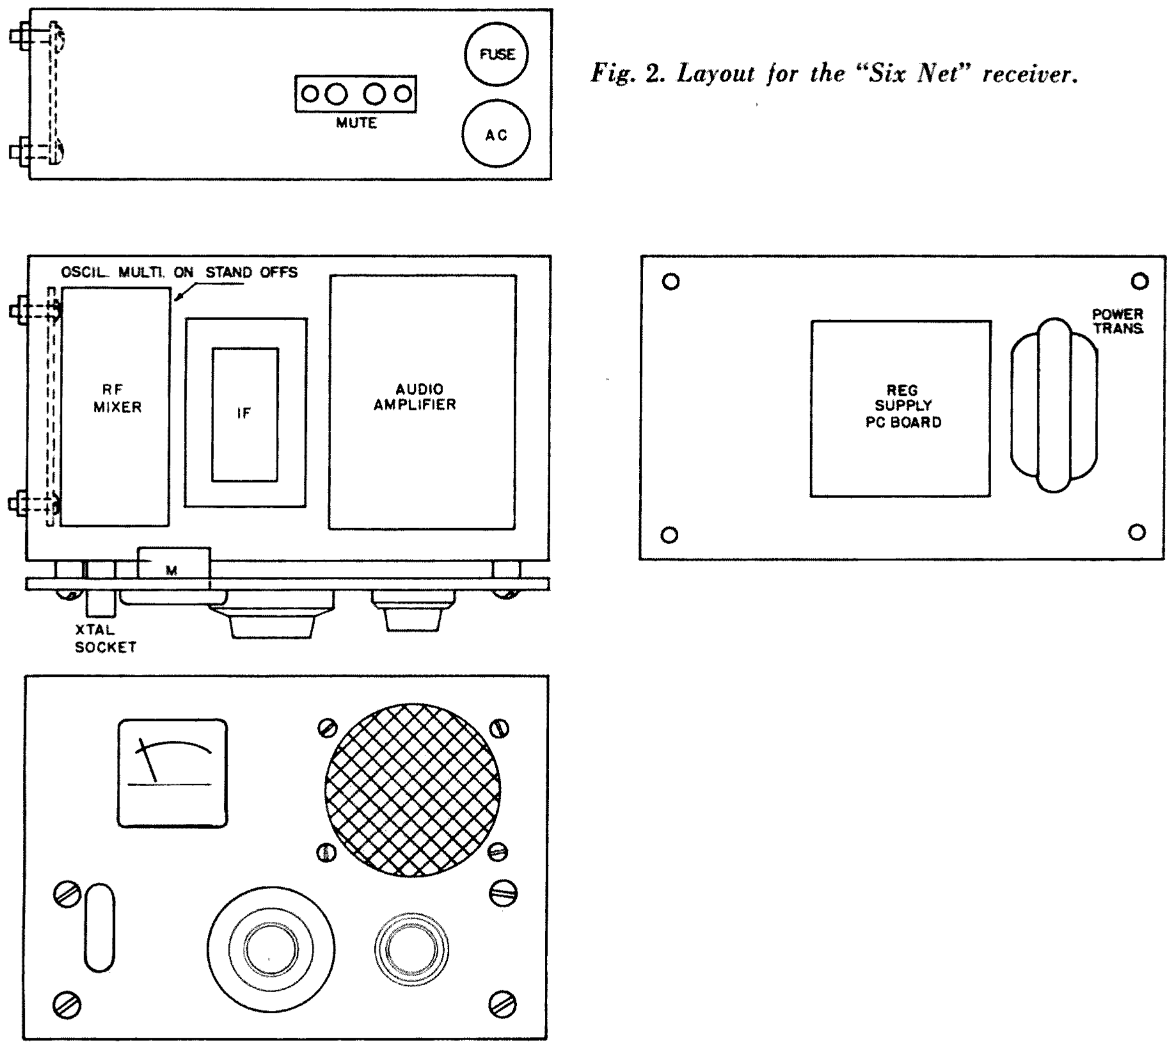

Fig. 2. Layout for the "Six Net" receiver.

airplane dope will do. It takes approximately 25 to 30 minutes to etch, depending on the strength and temperature of the solution. After the PC boards are completed, drill all holes to take the components and solder them in place. The Miller *if* strip sells for less than $6.00 from Allied Radio. The Miller part number is 8902-B. The transistor driver and output transformer are the standard run-of-the-mill transformers. Almost any of the electronic supply houses have them. The power transformer is an Allied 6.3 @ 0.6A number 54-1416. If anything larger is used it may not fit inside the chassis.

I used a Bud 4 x 6 x 2 inch chassis. The chassis was cut out to take the PC boards as illustrated, except for the oscillator and the regulated power supply. These were mounted on stand offs. The oscillator multiplier is mounted on ½ inch stand offs on the left inside of the chassis below the rf mixer and at right angle to it. The power supply board is mounted on ⅜ inch standoffs on a 4 x 6 x ⅛ inch sheet aluminum which is used for the bottom cover plate. Make cut outs for the meter, speaker, crystal socket, variable frequency control, and the volume control, as illustrated. I used ¼ inch standoffs between the panel and chassis for easier assembly. Cut out the holes on the front and rear of the chassis for the controls on the front, and the ac line, fuse holder, antenna connection and muting terminals on the rear. Assemble the receiver as indicated on the schematic and illustrations.

After the wiring has been completed, check it very carefully, making sure no mistakes were made. Dip the rf and mixer coils to approximately 50.4 Plug in an 8325 Hz crystal and turn on the receiver. Ad-

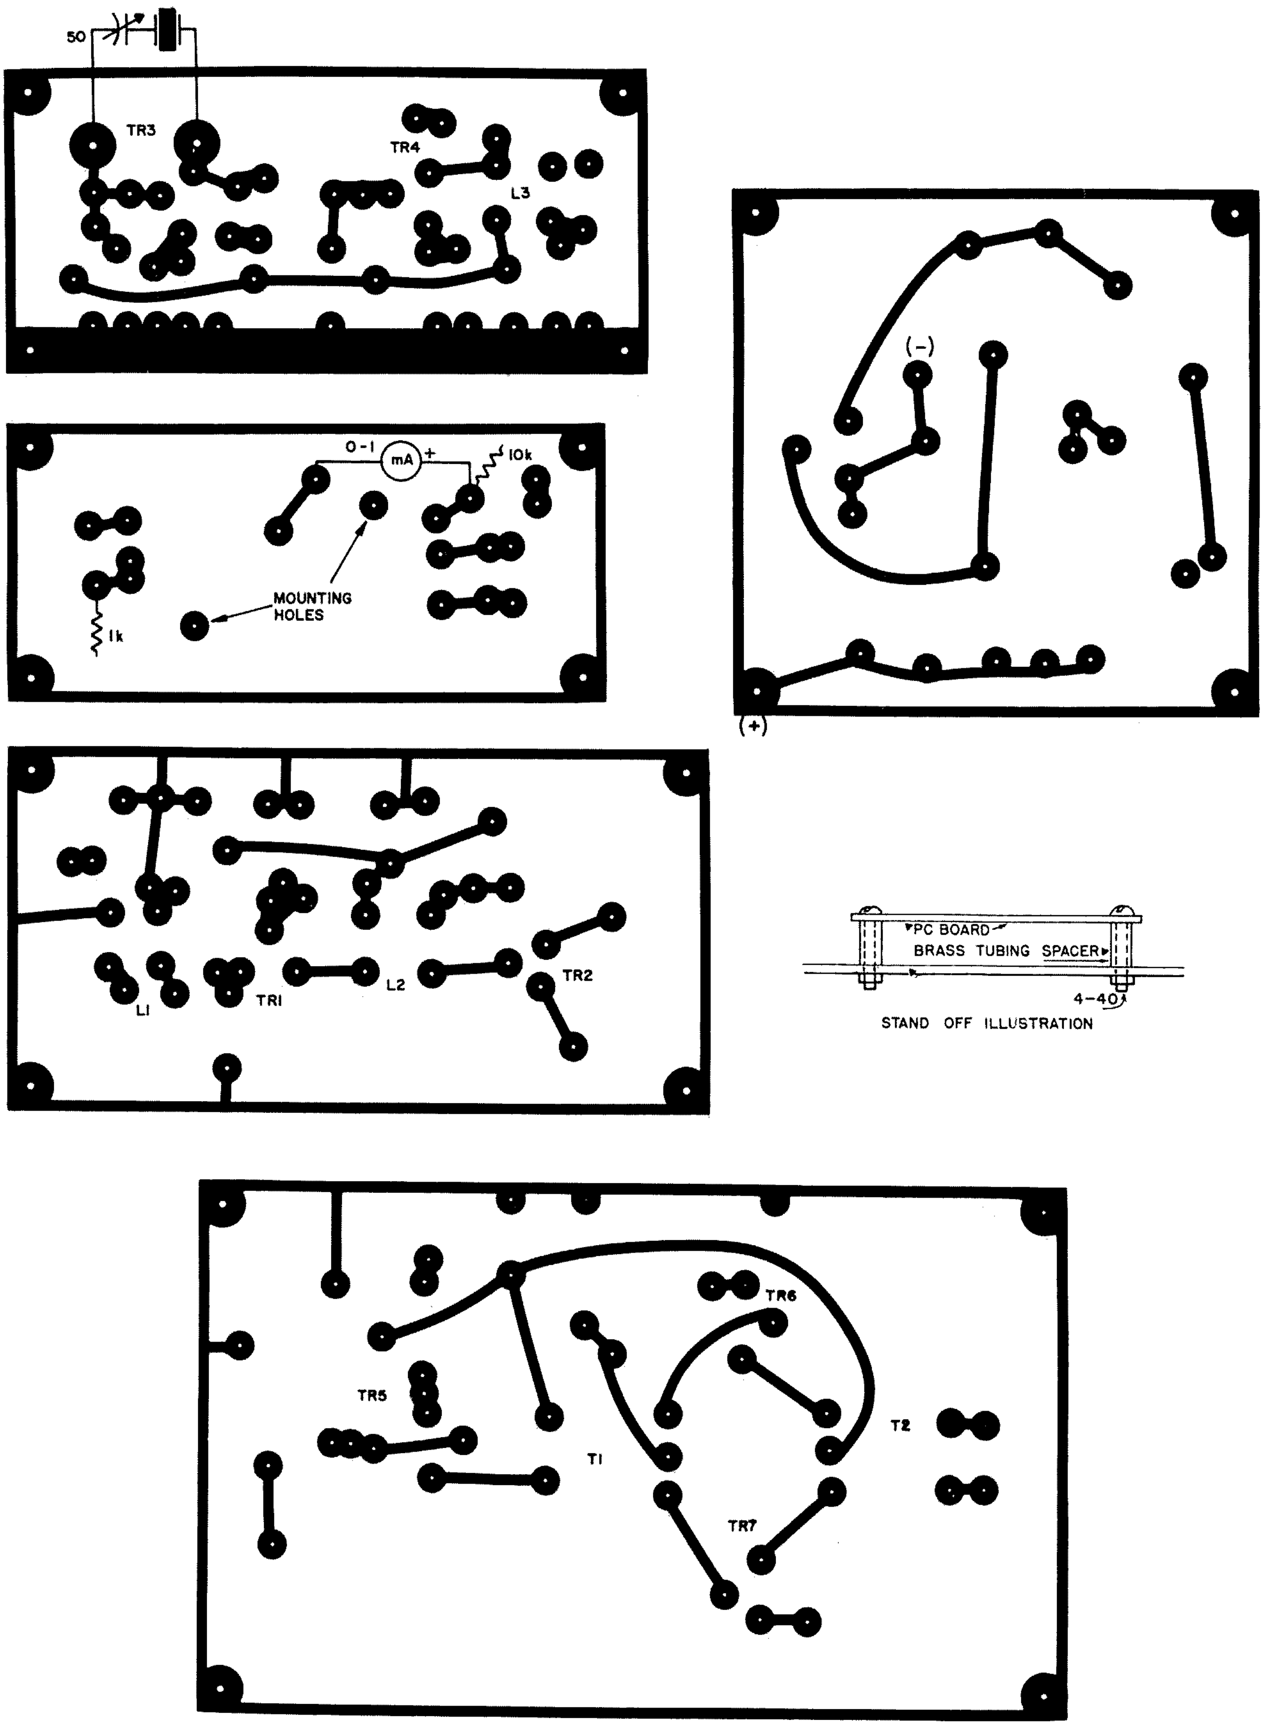

Fig. 3. Printed circuit patterns.

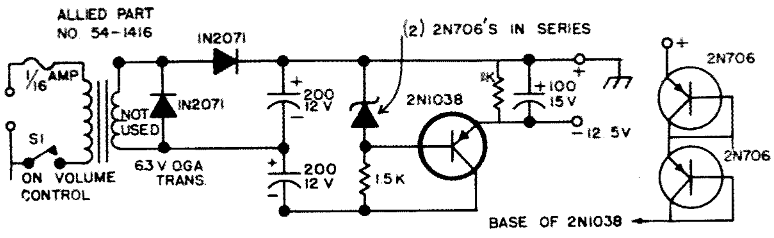

Fig. 4. Diagram for the power supply for the "Six Net" receiver.

just L3 for maximum output with a VTVM. By doing this the receiver will cover frequencies between 49.98 and 50.8 MHz without readjusting L3. Peak L1, L2 and the Miller *if* strip using a signal generator or on the air signal. Here I used the S meter to peak the receiver. The meter will dip, not increase with increase of signal.

The oscillator was checked for stability with a Hewlett Packard counter. The results were no more than plus or minus 20 Hz for any one hour period. I watched the counter for a 15 minute period and observed only 5 Hz change. The tests were made with an 8 MHz xtal.

I have been using the receiver on MARS nets for the past 3 months with excellent results. Here is one receiver which does not require readjusting unless the other stations are off frequency. This will not do for a knob twister.

. . . W5JSN

Pill Box Makes Module

The cylindrical pill box used by most druggists can be made into a module for small electronic circuits. Just take the top off the box and attach an octal plug to the top. The exact method of doing this will depend on whether you use a commercial plug or a salvaged tube base. Now build your circuit so that it fits in the pill box and solder all the power, signal and ground leads to the octal plug with all connections corresponding to the mating socket. For permanence, a bit of epoxy glue will keep the top of the box and the box proper together. A natural use for this type of module is a solid state rectifier replacement for tube rigs.

Pill boxes can also be used to cover relays and keep dust from causing erratic operation.

If you are luckier than most people and don't take pills, you can buy these pill boxes from a druggist for about a nickel apiece.

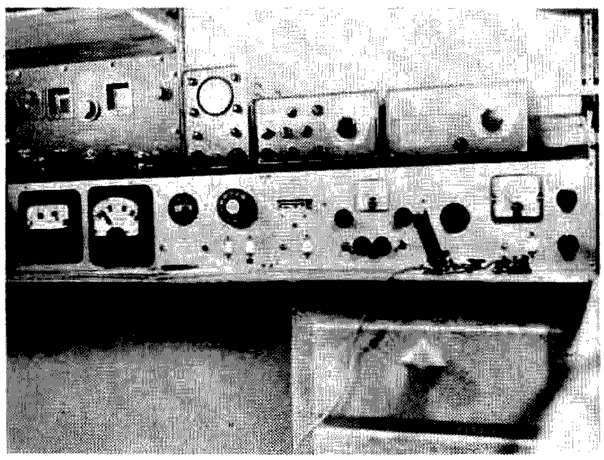
An Operating Console

P. Kimball W6GDP
583 Market St.
San Francisco, Calif.

Suggestions for Dressing up the Station and Improving Operating Convenience



Most of us started in amateur radio with rather simple equipment in the shack, i.e., transmitter, receiver, mike and key. We all have a tendency to improve and upgrade the station by adding outboard accessories. If you are a typical amateur, the chances are that, after a short time, your operating position will begin to resemble a storage area for black boxes, meters, dials and wires. These outboard accessories usually include: clock, SWR bridge, voltmeter, phone patch, field strength meter, antenna switch, telephone, ten minute timer, etc., et al.

As a first step in improving the appearance of the station, as well as operating convenience, the author decided to mount all the outboard equipment at his station in one console. The photo shows this console which includes all of the above mentioned accessories with room left for future expansion.

The console front was made from ⅛" aluminum panel and the case from ⅜" plywood on a 1" frame, well reinforced. The accessories, which were already mounted in boxes or cabinets, such as the SWR bridge, were installed in the panel after first making a cardboard template of the parts which would project through the panel, to aid in their cutout; then the boxes were mounted against the panel by metal straps.

All panel cutouts were made with ¼" electric drill and sabre saw using a metal cutting blade. A valuable aid in working wih aluminum, using electric hand tools, is an SCR speed reducer to limit the speed to fit the condition; several such kits are on the market.

The console overall dimensions should be adequate to house the equipment to be installed and should be sufficiently sturdy to support the transmitter, receiver or other equipment which may set on top. It can easily be built into a desk at an angle if a sloping face panel is desired. The overall dimensions of the author's are 51" long, 8" high and 15" deep.

It was decided to monitor both ac voltage and current using switchboard type meters which are usually available surplus at very reasonable cost. The ammeter reads direct from 0 to 5 amps. An additional scale from 0 to 25 amps (to be used when a linear is in operation) was incorporated by switching in a surplus 200 to 5 amps ratio current transformer in the primary. Eight turns of the primary 120 volt wire through the transformer window will produce 5 amps in the transformer secondary with 25 amps flowing in the primary. Other ratios are usually obtained by varying the number of turns. **Fig. 1** shows the complete 120 volt ac power wiring which should be at least #10 in size but in no case smaller than that required to carry the current and meet

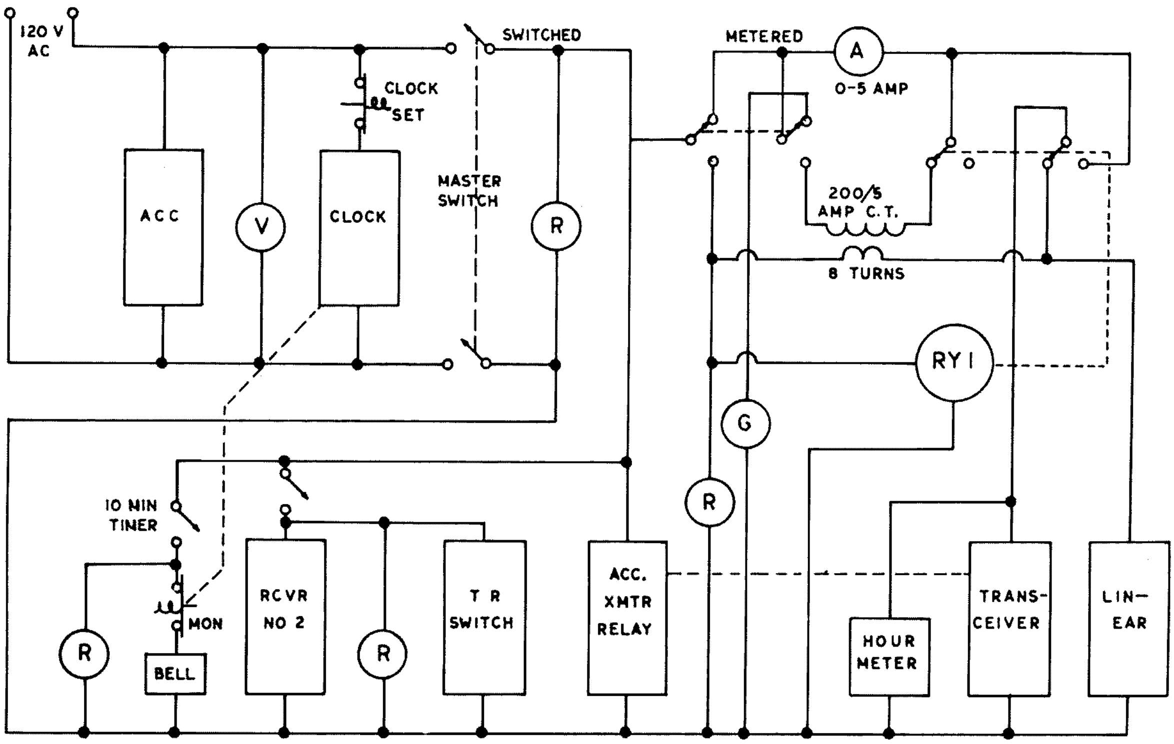


Fig. 1. Complete 120 volt AC wiring.

all applicable codes. The back of the console contains recepticles for the ac lines from the transmitter, receiver, linear etc. It also holds the inputs for mike, telephone and tape recorder as well as an additional relay for muting outboard receivers, lighting "on the air" sign, etc. This relay is operated by an auxiliary contact on the antenna relay on the transceiver. The totalizing hour meter is 110 volt ac surplus and indicates total heater hours on the transmitter. Additional meters may be used to show plate hours, linear heater hours, etc.

Fig. 2 is a block diagram for the *rf* circuit and audio circuits. The coax switch allows any of three antennas or a dummy load to be selected. The audio input selector switch is a three pole, six position rotary type which should be shielded.

The console also includes a mike preamplifier and speech compressor. The telephone dial was mounted on the front panel and the hand set on the side for convenient use. In addition, a hybrid phone patch is installed which can be cut in and out at will. With the patch cut in, the receiver

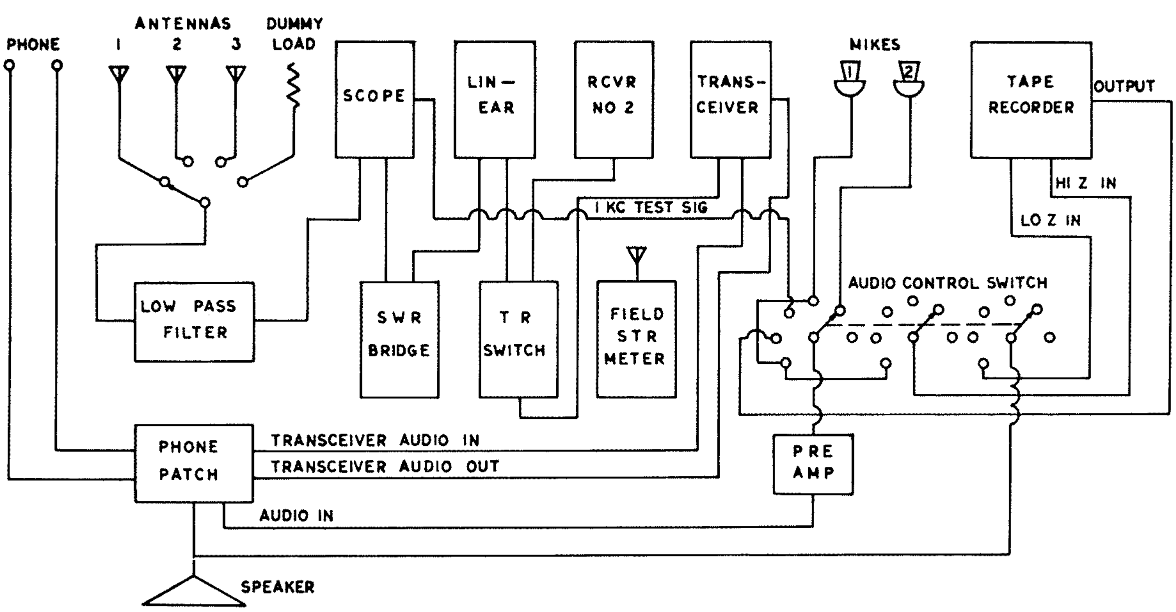

Fig. 2. Block diagram for rf & audio circuits.

speaker is muted, and monitoring is accomplished through the receiver portion of the hand set. The ac switches are rocker type and the pilot lights are inexpensive 110 volt neons. The aluminum panel is easily obtained from surplus. Before mounting the equipment on the panel it can be given a pleasing "brushed" appearance by sanding lightly and spraying with clear acrylic or if desired, painted with a high grade switchboard enamel.

All stations tend to become personalized because of different equipment and individual preferences. This article was written merely to suggest some ideas on approaching the design of a functional console, and details have been purposely omitted. The two factors of operating convenience and pleasing appearance are most important and the author's console has added much real pleasure to operating in addition to bringing admiring glances from visitors to the shack. A construction project of this type is relatively simple and offers much satisfaction for those of us who have a yen to build a part of the equipment in the shack, yet do not feel technically competent to tackle modern transmitter or receiver design and construction.

. . . W6GDP

Rack Those Test Leads

Is your workbench always cluttered up with test leads that somehow seem to get tangled up with everything else? Do you spend more time looking for and then untangling a special test probe or jumper wire than you spend in the actual process of testing or jumping?

If you do, you no longer have to. Just go down to the local drug store or department store and ask one of the employees for an old display rack. These racks hold everything from combs to small packaged items and when all the products on the rack are sold, usually the rack is discarded. But you can use such a rack to store your test leads in a 'civilized' manner. The appearance of your workbench will be 100% neater!

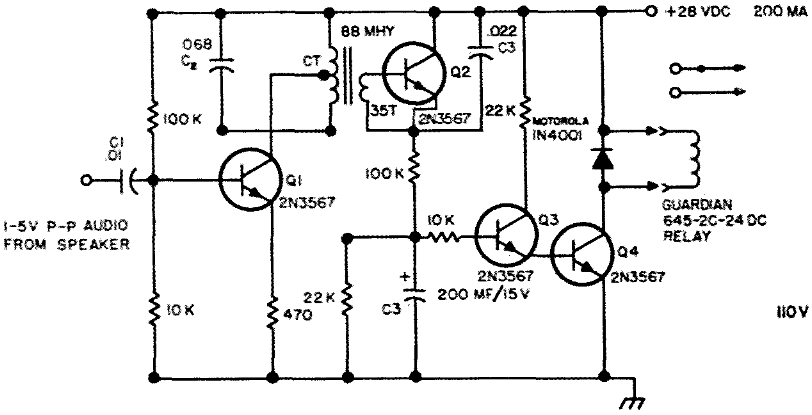
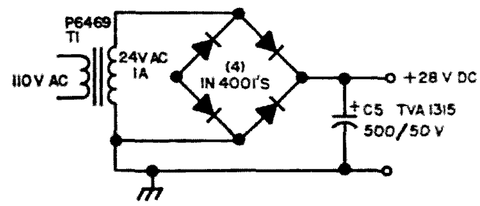
RTTY Autostart

Thomas R. O'Hara W6ORG
10253 E. Nadine
Temple City Ca 91780





This autostart circuit is versatile in that it connects to the speaker instead of digging into the TU, is solid state and therefore small, and can be hooked up to turn on the teletype machine and TU power. The power supply requirement is +24 to 28 VDC at 10 mA no signal to 200 mA with signal. This autostart was designed originally for monitoring USAF MARS VHF nets where both voice and teletype are used. Many stations operate on VHF and HF SSB simultaneously. With this device it is not necessary to stop copying on HF to turn on the teletype machine. It insures that you receive all RTTY copy on the net.

The first transistor is a tuned amplifier. The input audio must be in the range of 1 to 5 volts peak to peak which is the normal listening range voltage for a 4 to 8 ohm speaker. For a 600 ohm impedance a resitive devider consisting of a 1 k and 10 k resistor or a 600 to 8 ohm transformer must be added. The tuned circuit is resonant to the standard mark frequency of 2125 Hz. Any combination of L and C may be used for other tone frequencies for selective call, etc. The coil is the usual 88 mH toroid available on surplus. Bandwidth is approximately 150 Hz. The .068 capacitor should be a good mylar type for frequency stability. Turns may have to be taken off to get exact resonance for best performance. If the .068 capacitor is close to tolerance, about 35 turns should be taken off. The link couples about one volt at resonance to the switch transistor Q2 which then turns on and allows the 100 mfd capacitors to charge up. When this charging voltage gets up to 1½ volts the relay drivers Q3 and 4 turn on and energize the relay. The 100 k resistor with a 100 ohm relay gives about 3 seconds before turn on. Likewise it takes about 3 seconds to drop out in absence of a steady mark tone. The time out is determined by the relay coil resistance and the 22 k resistor. Both the 100 k and 22 k resistors can be varied for any desired time in and out up to 10 seconds.

Operation

Hook up the input to an audio source of 2125 Hz and take off 5 turns at a time from the hot side of the toroid until maximum voltage is shown on a scope or ac VTVM. Check the time in and out of the relay and change the 100 k and 22 k resistors for the desired length of time. The relay should have 10 amp contacts because of the starting current of the teletype machine.

Construction can be on a chassis, vector or PC board as the circuit is not critical to pickup or capacitive effects as with other types of autostarts. I can supply a PC board for $2.50 or a completed tested unit for $15.00 post paid.

This circuit is great for both the lazy man and the busy man and ensures that you get all the teletype copy on the net.

. . . W6ORG

Oscillator Frequency-Shift Calculations

Jack McKay WA6DPD/3
3516 Camp St.
Pittsburgh, Pa. 15219

It is always of interest, when designing an oscillator, to know how much frequency shift will result from a change in component values, whether intentional or unintentional. A few equations for such calculations are given here.

I. An approximate equation for relative frequency change $\frac{\Delta f}{f}$ caused by a relative capacity change $\frac{\Delta C}{C}$ or a relative inductance change $\frac{\Delta L}{L}$:

$$\frac{\Delta f}{f} = ½ \frac{\Delta C}{C} = ½ \frac{\Delta L}{L}$$

Suppose, for example, that a tuned circuit with C = 100 pF, L = 1.27 uh, f = 14.0 MHz uses a fixed capacitor with a negative temperature coefficient of 750 parts per million per degree Centigrade, and the ambient temperature rises 5° C. The change in capacity is $750 \times 10^{-6} \times 5 \times 100 = 0.375$ pF. The relative change in capacity is $\frac{0.375}{100}$ = 0.00375. The frequency will increase by approximately

$$\Delta f = ½\, f \frac{\Delta C}{C} = ½ \times 14.0 \times 0.00375$$

$$= 0.02625 \text{ MHz} = 26.25 \text{ kHz}$$

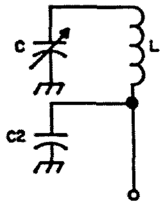


Fig. 1. A bypass capacitor in a tuned circuit.

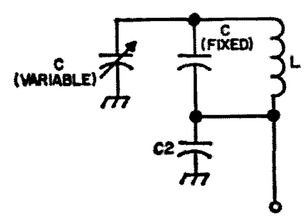

Fig. 2. A fixed capacitor wired on the inductor side of the circuit.

The new resonant frequency will be about 14.026 MHz. Working out an exact answer is long and laborious, and cannot be slide-ruled because of the great accuracy needed for calculating an increase in frequency of less than 0.2%. A more precise result for the new resonant frequency is 14.02633 MHz, virtually identical to the result obtained using the simpler equation.

Conversely, if a zero-temperature-coefficient capacitor is used in the above tuned circuit, and the frequency is observed to drift down 26 kHz when the temperature increases 5° C., substitution of an N750 capacitor will reduce the drift to near zero.

This equation can also be used for rough calculations of the capacitors necessary to tune a given frequency range. Suppose it is desired to tune 7.00-7.30 MHz and a 6-80 pF variable is available. How much fixed capacity is necessary in parallel with the variable to tune the range?

The relative frequency change is $\frac{\Delta f}{f} = \frac{0.300}{7.150} = 0.042$. The relative capacitance change must be twice this, or 0.084. The capacitance change available is 74 pF, so the total capacity at center frequency must be $\frac{74}{0.084} = 882$ pF. Center capacity of the variable is 43 pF, so 882 − 43 = 839 pF is required in parallel with the variable to tune this range.

II. An exact equation for the frequency range tuned by a variable capacitor with capacity range ΔC, or by a variable inductor with inductance range ΔL, is

$$\left[\frac{f_1}{f_2}\right]^2 - 1 = \left[\frac{f_1}{f_2} + 1\right]\left[\frac{f_1}{f_2} - 1\right]$$

$$= \frac{\Delta C}{C_1} = \frac{\Delta L}{L_1}$$

where f_1 = resonant frequency for $C = C_1$ or $L = L_1$ (the higher resonant frequency)

f_2 = resonant frequency for $C = C_1 + \Delta C$ (variable capacity) or $L = L_1 + \Delta L$ (variable inductance)

Taking the example above, with the 6-80 pF variable capacitor for the frequency range 7.00-7.30 MHz, and calculating C_1:

$$\frac{f_1}{f_2} = \frac{7.30}{7.00} = 1.4029$$

$$C_1 = \frac{C}{\left[\frac{f_1}{f_2} + 1\right]\left[\frac{f_1}{f_2} - 1\right]}$$

$$= \frac{74}{(2.0429)\ (0.0429)} = 844 \text{ pF}$$

This is the minimum capacity, for resonating at the higher frequency; allowing for the 6 pF minimum capacity of the variable, 838 pF (less stray capacitances) is required in parallel with the variable.

The close agreement between the calculation with the approximate equation and the exact equation is due in this case to blind luck. For $\frac{\Delta f}{f}$ above a few percent, when accurate results are needed, the exact equation must be used; for very small $\frac{\Delta f}{f}$ or where only approximate results are needed, the simpler equation can be used.

III. Frequently a bypass capacitor is used in a tuned circuit, as in **Fig. 1.** The bypass and the tuning capacitor are effectively in series. How much frequency drift is caused by a variation in the capacity of the bypass? An approximate equation for the net change in capacity of the two capacitors in series is

$$\frac{\Delta C}{C} = \frac{C}{C_2}\left[\frac{\Delta C_2}{C_2}\right]$$

where C = capacity of tuning capacitor (about the same as the net capacity of the capacitors in series)

C_2 = capacity of the bypass capacitor

ΔC_2 = change in C_2.

Suppose that $C = 844$ pF, $f = 7.30$ MHz, and $C_2 = 0.02\ \mu F$ with temperature coefficient 1% per degree Centigrade (typical for general-purpose ceramics). For a temperature rise of 5° C., the change in C_2 is 5%; $\frac{C_2}{C_2} = 0.05$. Then

$$\frac{\Delta C}{C} = \frac{844}{20{,}000} \times 0.05 = 0.00211$$

The first equation of this article can be used to calculate the frequency drift:

$$\Delta f = \tfrac{1}{2} f \frac{\Delta C}{C} = \tfrac{1}{2} \times 7.30 \times 30 \times 0.00211$$

$$= 0.00766 \text{ MHz} = 7.66 \text{ kHz}$$

Since C_2 is increasing, the resonant frequency decreases by 7.66 kHz. Thus the tuned circuit components could be perfect, and the drift would still be excessive for a VFO, because of variation in the bypass capacitor.

This drift can be sharply reduced in this case very easily. The tuning capacitance C is made up of a variable in parallel with an 838 pF fixed capacitor. Suppose the fixed capacitor is wired on the inductor side of the circuit, as in **Fig. 2.** Then the bypass is in series with only the 6-80 pF variable capacitor. At the high-frequency end the variable capacitor contributes only 6 pF and the variation in bypass capacity will be entirely negligible. At the low-frequency end ($f = 7.00$ MHz) the variable is set at 80 pF, and the effective change in capacity for a 5-degree heating as before is

$$\frac{\Delta C}{C} = \frac{80}{20{,}000} \times 0.05 = 0.0002$$

or $\Delta C = 0.0002 \times 80 = 0.016$ pF.

Then, using the first equation for $\frac{\Delta f}{f}$,

$$\Delta f = \tfrac{1}{2} f \frac{\Delta C}{C} = \tfrac{1}{2} \times 7.00 \times \frac{0.016}{(838 + 80)}$$

$$= 6.1 \times 10^{-5} \text{ MHz} = 61 \text{ Hz}$$

The drift is less than a hundredth of what it was with the fixed capacitor on the tuning-capacitor side of the bypass.

Note also that increasing the bypass capacitance with temperature coefficient unchanged decreases the frequency drift. Therefore bypass capacitors for high-stability oscillators should be as large as internal resonances permit.

. . . WA6DPD

Accurate if Alignment

I hear many hams talk of the trouble they have in accurately aligning the *if's* of their receivers, especially some of the newcomers using a converted surplus receiver. I have been using the procedure listed in **Fig. 1** for years, and find that most receivers will come close to reading correctly if the *if's* are set correctly before any *rf* or oscillator alignment.

As all American BC stations use 10 kHz separation and are crystal controlled, I use them to check signal generator settings. For instance, suppose I want to align a receiver with an *if* frequency of 1680 kHz. Setting the signal generator at 420 kHz, its 2nd harmonic should zero beat with a broadcast carrier at 840 kHz. Then its fourth harmonic is within a few cycles of 1680 kHz, and is used for the *if* alignment. To align a 455 kHz *if* accurately, I zero beat the signal generator's second harmonic of 455 kHz against a 910 kHz broadcast carrier, and align from the fundamental.

This approach is very accurate, and the signal generator needs a 30 minute warmup before doing alignment work. If the receiver *if* is known to be far off, I do a rough alignment before using the above procedure.

If Freq. of rcvr.	Sig. gen. setting	BC station zero beat at:	Harmonic beat with BC sta.	Harmonic for alignment
260 kHz	260 kHz	780 kHz	3rd	Fund.
262 "	262 "	1310 "	5th	"
266 "	266 "	1330 "	5th	"
455 "	455 "	910 "	2nd	"
915 "	305 "	610 "	2nd	3rd
1650 "	330 "	660 "	2nd	5th
1680 "	420 "	840 "	2nd	4th
1750 "	350 "	700 "	2nd	5th

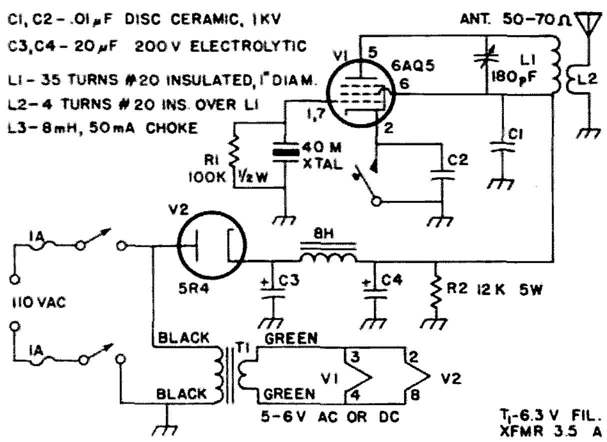
A Ten Minute 40 Meter Rig



The rig described here should fill the bill for a standby when the big rig breaks down, or to persue QRP hamming. The transmitter can run about 15 watts on 40 into a 50-70 ohm load. If power is borrowed from another source, all the rig consists of is a tube, a resistor, two capacitors, and a coil. You should be able to build it breadboard style in the time it takes the station receiver to warm up!

The circuit is a simple crystal oscillator making use of the pentode tube. The circuit is tuned by the plate to cathode capacity within the 6AQ5. The final is dipped by permeability tuning of the coil. A similar triode circuit was popular during the '30s using 6L6's, which you old timers may remember.

Start scrounging the parts from old TV's which can be obtained for the asking from service shops. The old sets contain plenty of goodies; a husky power transformer, capacitors, resistors, chokes, a speaker, and some FB tubes.

Almost all of the parts can be found inside a TV set of late vintage. You may have a bit of trouble locating the 6AQ5, but be persistant and you will find one, usually after looking through about half a dozen sets. Because of the low level of *rf*, the socket can be the original ripped out of the set, and not a special porcelain one. While C_1 and C_2 are specified as .01 μF they can be almost any value that your TV set uses for bypassing. Anywhere from .005 μF to .02 μF is fine here. L_1 is wound on a one inch diameter cardboard form and consists of about 35 turns of #20 wire. This amount of inductance is not enough to resonate the circuit at 40 meters, but more inductance is added later by inserting a ferrite rod into the coil. A two inch piece of a loopstick from an old BC radio is ok for this. Wind L_2 directly over L_1, about 25 turns from the hot end. Be sure to wind it in the same direction or you will get a phase shift in the output signal. Twist the ends of L_2 after winding to keep it from unwinding. A tube socket from the television or a similar receptical can be used for the crystal socket. A special crystal socket doesn't seem to be necessary.

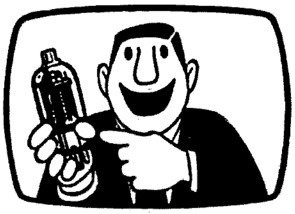
The easiest way to supply power to the rig would be to borrow it from another source. A BC radio, record player, or tape recorder will usually provide about 150 volts of B plus. That's enough to run about two watts input. The power supply I used is of the ac-dc type. The TV should contain a suitable five volt rectifier, choke, and electrolytic capacitors. Check the caps with a VOM to be sure they are not shorted before using them. The choke, L_3 is not critical and can be anything that resembls a choke. You can even use the primary of the TV's speaker output transformer. Bleeder resistor R_1 is also not critical but should be about 100 ohms per volt that the power supply will handle. Be sure that R_2 is conservatively rated, because a blown bleeder resistor is more dangerous than none at all. Also, if you use an ac-dc power supply don't try to connect it to an earth ground or use a VFO with a grounded shield on its output. If you do, stock upon plenty of fuses for your house.

To put the transmitter on the air, hook one side of L_2 to a 50-70 ohm antenna. Plug it in and give it the smoke test. If

everything is ok, insert the ferrite rod into the coil and tune for a dip on a 0-50 mA meter connected at point "X". Tape a cardboard arm about four inches long to the ferrite rod so the final can be dipped without being detuned by your hand. The current at resonance will be between 10 and 40 mA, depending on the B plus voltage.

Running about one watt input on 40 meters to a dipole here in two-land, I can work four and nines nightly, and occasionally a zero. I have really been surprised at the performance of my li'l rig, as I know you will be.

...WB2YOJ



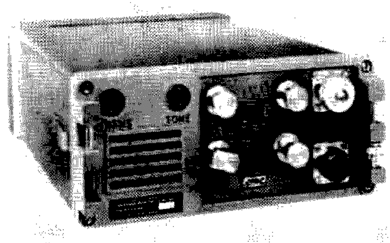
NEW PRODUCTS

Amphenol Hobby Booklet

A nice photo, and look again. This is 15-year-old Barry Meyer of Park Forest, Ill., assembling a SWR bridge. But there in the foreground are an Amphenol blister-pak RF-58A/U coax fitting (with assembly data on the back of the package) and, under the pliers, a copy of Amphenol's new hobbyist booklet.

This booklet is a handy reference guide, to be used and kept on the workbench. It contains information on how to solder, interpret schematic symbols, read resistor color codes, etc.

Ask at your distributor's for the Amphenol Blister-Paks, which are being used as packaging for a wide variety of components. And you can get one of the workbench guides by sending a self-addressed stamped envelope to "How-To Handbook," Amphenol Distributor Division, The Bunker-Ramo Corporation, 2875 S. 25th Ave., Broadview, Ill. 60153



Very Portable Transceiver

A rugged new transceiver should be very useful for groups needing emergency transceiver facilities. The Kaar Electronics Corporation has introduced an all-solid-state SSB/CW transceiver for shoulder-pack or fixed location communications work. Rated at 10 watts PEP, the transceiver can be operated from D-size heavy-duty cells, from a 12-volt dc car or battery system, or through an adapter from an ac power line. Receive and transmit frequencies are crystal-controlled in the 20, 40, 80 or 160 meter bands.

For details on their Kaar ComPact 24, write the Kaar Electronics Corporation, 1203 W. St. Georges Ave., Linden, N.J. 07036.

New Books from Sams

Sams has announced several new and reprint books for electronics workers.

ABC's of Electronic Test Equipment, by Donald Smith, ($2.95) is out as a 2nd edition. This is a basic text with information on VOM's, VTVM's, component testers, signal generators and tracers, oscilloscopes, multiples and color bar generators, and other instruments. Sams #20660.

A new title, Practical Design with Transistors, by Mannie Horowitz ($5.95) uses the direct approach to designing biasing, feedback and high-frequency circuits, and includes data on recent semiconductor developments and new FET applications. Sams #20659.

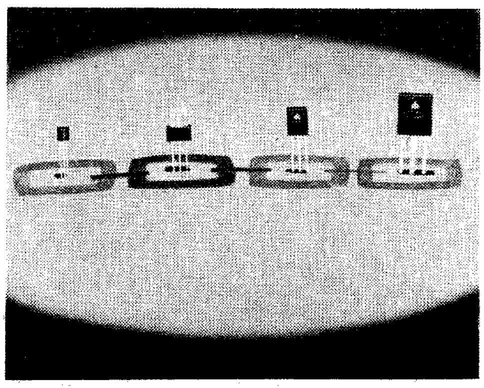
Using Scopes in Transistor Circuits, by Robert G. Midleton ($4.95) includes waveform discussions and solid state circuit theory relevant to oscillators, amplifiers, waveshaping circuits, and monochrome and color TV, and electronic computers. Sams #20662.

Robert M. Brown's 101 Easy CB Projects ($3.25) describes an entertaining collection

of simple, practical CB projects. Parts lists and construction details are included. Sams #20663.

The North American Radio-TV Station Guide, by Vane A. Jones, ($2.95) appears in a new 5th edition. Listings include frequencies, call letters, locations, and network affiliations, and other data for AM, FM, and TV stations in the U.S., Canada, Cuba, Mexico, and the West Indies. Over 9500 assorted stations are listed. Sams #20635.

Write to R. R. Fleck, Howard W. Sams & Co., Inc., 4300 W. 62nd St., Indianapolis, Indiana 46268 for further information. Try your distributors' too, since the books may already be there.



Motorola Uniwatt Transistors

Here are some new transistors to fill in the gap between little transistors and big transistors. Medium-size transistors.

Motorola's new Uniwatt transistors can dissipate up to 1 watt in air, or eight watts into a well-designed heat sink. All are silicon annular transistors, offering good high-frequency response. They are encased in plastic packages, with a copper tab for heat-sinking. See second from left in the photo.

Prices are quite low, and get up over a dollar for some of the Uniwatt transistors. For more information write to the Technical Information Center, Motorola Semiconductor Products, Inc., Box 20924, Phoenix, Arizona 85036.

The VHF Amateur

This informal, well-illustrated book is based upon Robert Brown's magazine "The VHF Amateur," which was the only monthly VHF magazine for a period of five years. Also titled "The VHF Amateur," the book

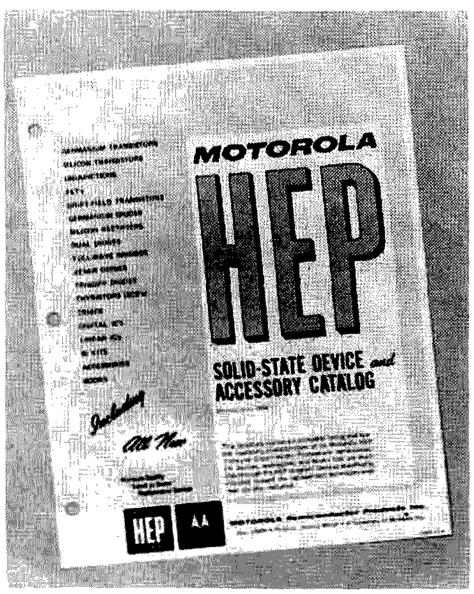
contains several projects from the magazine including some unusual antenna systems and details on two surface-wave transmission lines. This is the arrangement sometimes known as the "G-string."

Several pages are devoted to the construction of two styles of pen recorders, which are useful for moonbounce and space communications experiments. Some of the problems of antenna tilting are discussed also.

The popular Heathkit "Twoer" comes in for a discussion of possible further circuit development, and there are some notes on APX-6 conversion.

Other material includes schematics of TV tuners that may be converted for VHF applications, a very inexpensive 2-meter receiver, a 2-meter sideband transmitter and several other VHF projects.

Available from distributors or from Editors and Engineers Ltd., New Augusta, Indiana for $4.50.



New Motorola Catalog

Motorloa's large HEP line is still growing. Now it is up to 175 assorted devices, all listed in Motorola's latest HEP catalog. The listing includes many new entries of power, complimentary, and high-voltage transistors; a unijunction transistor, new integrated circuits, and several other items.

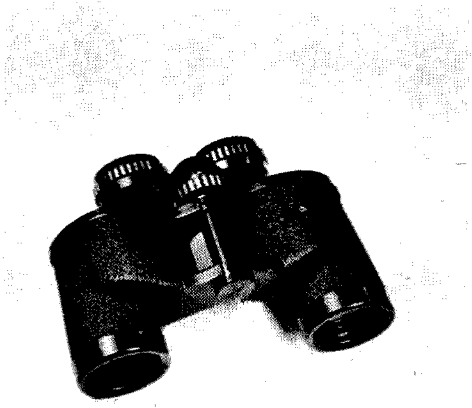
The new catalog also carries a list of "Equal-or-Better" replacement rectifiers, zeners, and transistors. Ask for Motorola's HEP catalog, MHA27-4, from any of the more than 1100 HEP distributors, or from the Technical Information Center, Motorola Semiconductor Products Inc., PO Box 20924, Phoenix, Arizona 85036.

Omega-T Bridge

A radio antenna is something like an appliance plug you push into a wall socket when you want line power for a light or an iron. It has to fit, but the critical electrical sizes for the radio antenna are not visible to the eye.

Many simple and complex electronic instruments are marketed for antenna testing. Basically, they all do the same job, indicating when the antenna is properly adjusted. Most of them require additional instruments, and for some a transmitter is needed too. But here is an instrument that gets by with only the gear that will be available anyway: the antenna, and the receiver that is to be used with the antenna.

The Omega-T Bridge circuitry does the rest of the job. There is quite a lot of it inside that little box, which accounts for its price. This excellent investment will be valued by any worker who is trying to get the best performance from a transmitting or a receiving antenna. This recently developed improved model antenna bridge noise bridge is now available at $34.95 from Omega T Systems, Inc., 516 W. Belt Line Rd., Richardon, Texas 75080.



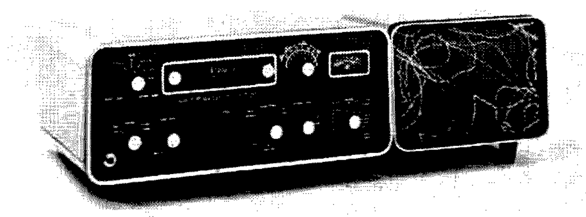
Micronta Binoculars

If you want to see what's going on up there in your tower, you can always pick up a handy pair of binoculars and look if you can find some binoculars.

Radio Shack has introduced a line of low-priced binoculars that are available in three varieties: normal, wide angle, and extra wide angle. All are the same magnification and size, 7 x 35, but offer fields 341, 525 and 578 feet wide respectively at 1000 yards.

The binoculars are available nationwide from Radio Shack's more than 340 outlets. They feature hard-coated lenses, aluminum frames and fast center focusing. All come complete with carrying case, wrist safety strap, and lens caps.

Priced at $19.95, $24.95, and $29.95 (for the widest field) the binoculars may be obtained from Radio Shack, 730 Commonwealth Ave., Boston, Mass. 02215 if they are not available locally.



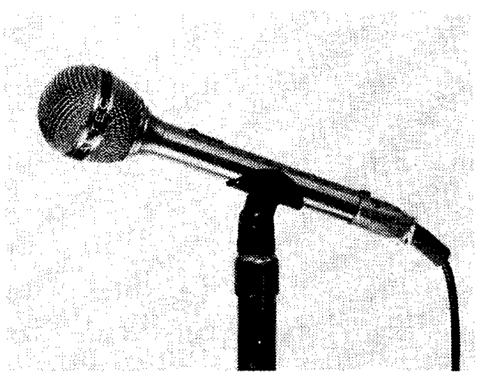
Hammarlund HQ-215 Receiver

The first fully-transistorized amateur receiver built to work with a matching solid-state transmitter. Hammarlund's HQ-215 is currently being shipped to distributors.

Technical features include modularized circuit design, and a unique carousel-type

dial with 22 inches of scale for a dial accuracy of plus/minus 200 cycles. Sensitivity is better than 0.5 microvolts for a 10 db signal to signal-plus-noise ratio. The HQ-215 uses 26 silicon transistors, 13 diodes and two zener regulators. It is supplied with one 2.1 kHz filter and has provision for two more.

Price is $529.50 with a matching speaker at $24.95. For further information write to Irving Strauber, W4KXD, Hammarlund Manufacturing Co., Mars Hill, North Carolina 28754

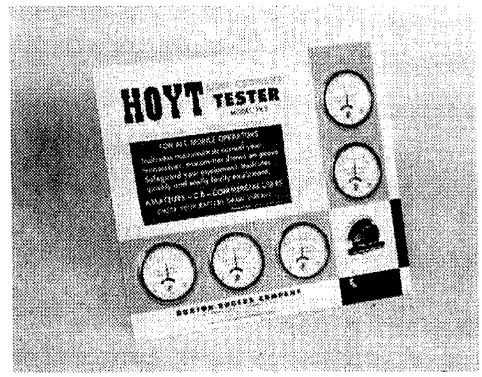


Response Tailored Microphone

Modern electronic devices and circuits tend to be inherently wideband. Additional circuit components are often required to reduce frequency response to that appropriate for most effective communications, but an alternative is to avoid introducing the unwanted frequencies into the circuit at all.

Altec Lansing's Model 650A cardioid dynamic microphone is specially designed for a limited frequency response. Its high frequency cutoff is fixed at 14 kHz, but the low-frequency response can be switched to either 50 or 400 Hz. And its cardioid response feature makes it far less susceptible than ordinary microphones to picking up interference and unwanted crowd noises originating from the side opposite the speaker. Front to back discrimination is 20 db.

The amateur net price is $75.00. For further details write to Don Palmquist, Altec Lansing, 1515 South Manchester Ave., Anaheim, Calif. 92803.

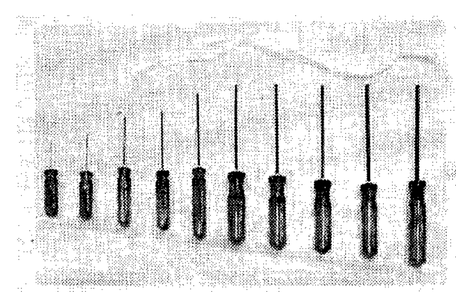


Hoyt DC Current Gauge

A part of good planning in mobile rig installation is to be sure where all the generator currents are flowing, and to know what the various operating currents really are. A conservative generator designer may have allowed no more than enough capacity for your rig, or perhaps somehow the battery runs down too much and it is not very clear what the trouble is. Such questions are best answered by measurements, but it may be difficult to break into the circuit at several different points. Hoyt's new current test meter makes this surgery unnecessary.

This convenient induction indicator responds to the magnetic field around a wire carrying up to 30 amperes. It will give a usable response to as little as one or two amperes, and indicates either direction of current flow. Without any cutting, you simply hold the meter against the wire.

Supplied five to the display card. Try your distributor for radio or automotive supplies, or write to the Burton-Rogers Co., 42 Carleton St., Cambridge, Mass. 02142.



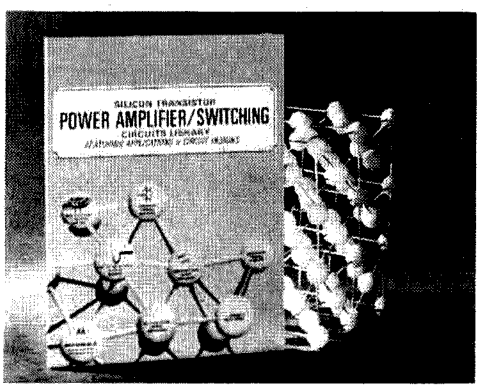
Small Tools

Hunter Industries is manufacturing a complete line of small and special-purpose tools for electronics assembly work. Some of these tools resemble but are imaginatively different from those you might find in your hardware store. For instance, the simple hex screwdrivers pictured above are not very

generally available, yet any bench worker knows hex nuts are pretty common in electronics gear. Think about having a set of hex drivers in your lab, and then write to Hunter Industries, 9851 Alburtis Ave., Santa Fe Springs, Calif. 90670.

Motorola Condensed Catalog

Motorola Semiconductors' new 1968 Condensed Catalog is an excellent hunting ground for bench-working hams looking for news about new semiconductor devices. It will be very interesting to electronics writers, too. It contains major specs on more than 3500 of Motorola's semiconductor types, and order information on about 9000 more. Semiconductor device mechanical dimensions are also given. Write to Department TIC, Motorola Semiconductor Products Inc., Box 13408, Phoenix, Arizona 85002.



Power Transistors Book

The growing importance of power transistor technology is becoming apparent in the higher-power and higher-frequency specs continually appearing in the engineering publications. Now Motorola has published an eighteen-section volume of technical literature describing applications for silicon power transistors.

Consumer and industrial applications are discussed, and the material is directed to users with less deep technical knowledge as well as to the trained engineer. A Selection Guide covers about 100 plastic and metal transistor types ranging from 3.75 watts to 200 watts dissipation.

From Motorola Semiconductor Products Inc., Box 955, Phoenix, Arizona.

Sudden UFO Interest Not Restricted To Hams

Ken W. Sessions, Jr. K6MVH
Technical Editor
Electro-Optical Systems, Inc.
300 N. Halstead
Pasadena, California

The radio amateur's interest in flying saucers may be more timely than one might at first suspect, for a similar interest was recently announced in Russia, a country with an earned record of ignoring such space phenomena. And when Russia takes a look at the world of flying saucers, that IS news! In what amounts to a complete reversal of official attitude toward flying saucers, Russia now rejects the tired explanations we Americans are accustomed to hearing: that UFO's are the result of "optical phenomena" and that they are quasi-natural occurrences of atmospheric or terrestrial origin. Russian scientists now go on record as offering their learned support to the hypothesis that UFO's originate on at least one other world somewhere in space.

In articles appearing in "Kimsomol'skaya pravda" and 'Teknika-Molodezhi," the Russian scientific community let pass a sequence of startling announcements that tend to confirm the need for a world-wide amateur radio "skywatch" plan. Included was a convincing conjecture that the famed Tungusky meteorite of 1908 was an artificial craft from another planet.

Information as to the contents of the two Russian scientific publications was released by Electro-Optical Systems, Inc., an aerospace firm in Pasadena, California, in a house-organ series entitled "Soviet Science in the News." The California firm, a subsidiary of the Xerox Corporation, makes regular translations of Soviet technical papers as a service to American scientists.

According to the Russian-to-English translation of the Soviet papers, there has been a number of recent Soviet investigations by the USSR's Academy of Sciences with respect to the Tungusky meteorite. The Tungusky explosion, the report said, had every parameter of an atmospheric nuclear blast and left considerable residual radioactivity. Also lending credence to the Soviet Academy's theory was the fact that the "meteorite" had apparently maneuvered immediately preceding the blast. The mysterious body exploded after apparently negotiating a 375-mile arc in the earth's atmosphere.

While the Russian's sudden interest in UFO's as a very real element of our times does not necessarily mean all old theories must be discarded, it does help to maintain an aura of sobriety in the discussion of a subject once reserved for the lunatic fringe.

Around The World

Algeria

Although the amount of equipment available is very limited as a result of strict regulations and an embargo on sending money out of the country, more licenses are expected to be issued shortly. At the present time there are 15 licensed stations in Algeria, seven held by nationals (7X2), five by foreigners (7X0), and three by club stations (7X2 plus three letters).

Five stations are active on 144 MHz, working into France, Italy and Spain. There is interest in SSB, RTTY and TV, but the equipment is just not available.

Bulgaria

During November a 15 day seminar was held in Sofia for instructors in Amateur Radio in order to help them improve their methods of teaching the theory of electronics. Operating practices for VHF and short wave, contest operating, construction practice, fox-hunting and the organization, conducting and judging of competitions were also discussed.

In December each of the 32 District Radio Clubs met in Sofia for a 15 day course on fox-hunting. Each participant had to build three fox-hunting transmitters for 3.5 and 144 MHz.

A special Jubilee International LZ DX Contest will be held on September 14, 1969 from 0000 to 1200 GMT on CW and SSB to mark the 25th anniversary of the Republic.

ITU–Geneva

The Administrative Council of the ITU has announced the intention to hold a World Administrative Conference in the latter part of 1970 to deal specifically with Space Radio Communications, Problems and Allocations. The exact dates, location and detailed agenda will be decided by the Council in May 1969.

Faroes

The annual meeting of the FRA was held in Thorshaven in October 1968. An activity contest was announced starting 1 Nov and ending 30 April 1969 on all bands, 3.5 to 28 MHz.

Italy

Radio manufacturers and dealers in Italy are required by law to provide purchasers of radio transmitters with a government certificate setting out the frequencies on which the transmitter may be operated and the maximum power that may be used. Just how this will affect home made equipment is not yet known. The small 11 meter Japanese walkie-talkies may give the authorities fits since many of them run well over the 10 mw permitted by law.

The ARI has petitioned their PTT for permission to operate in the 431.75-432.25 MHz band.

Netherlands

The Netherlands Government has extended its reciprocal operating agreement with the U.S. to include Surinam (PZ) and the Netherland Antilles (PJ), as well as the homeland.

Every Friday evening at 2030 GMT VERON transmits a broadcast in English on 14.1 MHz on RTTY. Reports will be appreciated.

Nigeria

The war with Biafra has held up the issuance of new amateur licenses. At present only stations in Lagos, Kaduna and Zaria can operate. Four members of the NARS are on the staff of the university at Zaria and a strong effort is being made to encourage students to take up amateur radio as a hobby. The SSB station at the university is 5N2AAU and is active.

Norway

The annual meeting of the NRRL took place in August. There are 2379 licensed amateurs in Norway, 258 more than the previous year.

A fund has been set up, with the aid of a government grant of $2100, to help the handicapped to become radio amateurs. IRC's for contacts with LG5LG will also go to this fund. This station has been set up in the Free State of Morokulien, an area surrounding the Peace Monument set up on the Norwegian-Swedish border. Send 3 IRC's for QSL or 4 IRC's for a direct QSL. Send $3.50 for an Honorary Citizenship in the Free State of Morokulien to the NRRL, Box 21, Refstad, Oslo 5, Norway.

Quick and Easy QRP

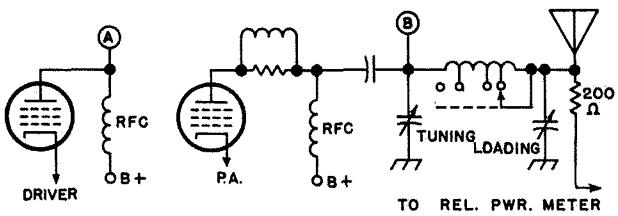

Fig. 1. External conversion of a VFO by adding an antenna coupler, a relative power output meter, and a TR switch.

Nearly every month one sees articles in ham magazines about some low power transistor transmitter. Have you ever had a desire to build such a rig but never got around to winding the coils or sending away for the transistors? But your laziness (and mine!) shouldn't stop you from enjoying QRP operations. This article describes two simple ways of using equipment in your shack to get you on QRP in a single evening.

In Method I a VFO is converted (externally) by adding an antenna coupler, a relative power output meter, and TR switch (See **Fig. 1**). If you don't have a separate VFO, Method II describes conversion of a medium power transmitter by removing the finals and connecting the driver to the pi-net (**Fig. 2**). I don't recommend crystal controlled low power operation, but it must be possible.

The modern VFO is actually a low power transmitter. It provides a fundamental on 80 and 40 meters and harmonics on 20, 15, and 10. It can be keyed from a terminal strip or jack on the back. The *rf* output is carried out through coax to the transmitter, or in this case, the antenna. The *rf* passes through a harmonic filter-antenna coupler, which consists of a tuned circuit LI-CL. LI is 30 turns of enameled wire, hook up close-wound on a 1 inch diameter cardboard tube. 13 turns are shorted out for 40 meters by SI. C1 was a 100 pF variable, but a standard 365 pF variable will do, though tuning will be a little more difficult.

The relative power output meter is fairly standard. The 5K pot, the sensitivity control, limits the amount of *rf* to the rectifier and filter. CI is tuned for maximum indication on the milliameter. Keep the reading low, as the current you read on the meter is not reaching the antenna.

With this setup, using an HA-5 VFO running five watts input,, I have worked into PEI (579) and Michigan (569); each over 700 miles away. Don't expect fantastic reports, but expect to get out. The number one requirement for QRP work is patience. You will probably not get an answer the first time, or even the second time. It takes a good ham at the other end to even bother to copy your station.

Remember that if your neighbor is running 100 watts,, medium power, you are 13 db below him to start, a little over 2 S units. Don't lose any power in your coax or dipole. My dipole, left over from my novice days, was resonant at about 7175 kHz. As this frequency was approached from the low end of 40 the relative output meter nearly doubled it's reading.

Also of prime importance is your receiver. If you want someone to copy you out of the noise, you must be able to do the same.

And just a word about operating. I wouldn't recommend sending CQ too much. It's better to come back to a CQ right where you can be easily found.

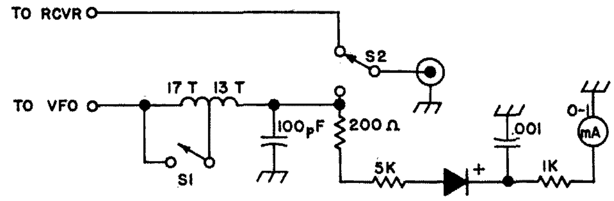

Fig. 2. Conversion of a medium power transmitter by removing the finals and connecting the driver to the pi-net.

Fig. 2 shows the final stage of a CW transmitter. Remove that big, ugly final. Connect a 1000 pF mica capacitor from the point A (the plate pin of the driver) to point B (the input of the pi-net). Since you can no longer tune up by plate current, you must add the relative power output meter circuit, or, in the case of a rig that already has one (like the T150A, which I modified), increase it's sensitivity. This can be done by decreasing the value of the dropping resistor that goes to the antenna jack to about 500 ohms. If the meter circuit is to be added connect the 200 ohm resistor as close as possible to the antenna, and bring a pair of twisted wires out to the pot.

This method offers the advantage of working all bands. Fifteen meters is an especially good band for low power. With fifteen watts input in a T150A I was 599 in Texas, about 2200 miles away. But 15 watts is high power.

Just a few more things. QRP offers a new challenge to hams. Like DXing, which is all it really is (though I've ragchewed for over an hour while my lunch was rapidly cooling) the antenna system must be perfect, for best results. Extreme patience is required, as well as a stable, selective receiver, and a good operator.

If you've ever had any TVI complaints, you won't now. Your rig is no longer strong enough to interfere!

A kindly OM was down at the shack the other day, and, being favorably impressed, made the following encouraging comment: "Why don't you plate-modulate the VFO? Take an audio transformer, hook it up backwards to the hifi, put the primary in series with the B+ to the plate of your final, and . . . He hasn't been invited back.

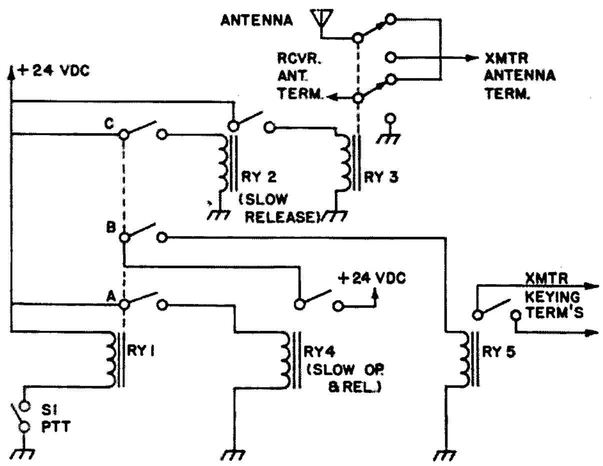
Full Sequential Switching with Simple Relays



Low-noise transistors in receiver front-ends are mighty fine and have a long, carefree life-provided, and only provided, they are not given a knockout blow from the transmitter rf.

This is all too easy to do at many amateur stations, and for absolute safety it is vital for the control-system to incorporate some form of sequential switching.

Good designs have been published, for instance "Ultimate Station Control" by W2AJW in 73 for Sept. 66, but most involve the use of many transistors or scarce high-resistance relays—and by Murphy's Law, the special type required is never available.

However, there are plenty of surplus 24-volt relays in all self-respecting junk-boxes, and this particular station control-system uses nothing else. In spite of its obvious simplicity, it gives full sequential switching, thereby automatically protecting those expensive front end transistors by making sure the receiver input is grounded and the antenna transferred to the transmitter well before the B-plus is applied to the PA final. And just as important, it sees to it that the B-plus is switched off before the antenna is returned to the receiver input.

Additional advantages are that all antenna switching is done "cold", without rf on the feeders, the transmitter output is always looking into a load, and when the control system is off, the antenna is connected to the receiver—all ready for a quick listen round the bands.

Details of relays

The relays required all have normal sets of contacts, which are "open" in the de-energised position.

RY1, which is the main control, has three such pairs (plus any additional ones which might be useful for killing the receiver B-plus).

RY2 is slugged with a copper ring round the heel or bottom end, as in **Fig. 2a,** and this causes it to be slow to release. If you do not happen to have one of this type around, quit worrying. Simply connect a small diode rectifier across the relay coil—the right way round as in **Fig. 3a,** so that it merely short-circuits the induced EMF, and not the applied voltage. Alternately, wire a resistor across the coil—about the same value as that of the coil—as **Fig. 3b.** Either will delay the release when put across an ordinary relay.

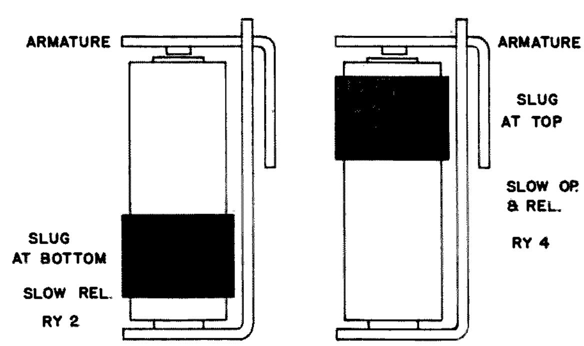


Fig. 2. See Text.

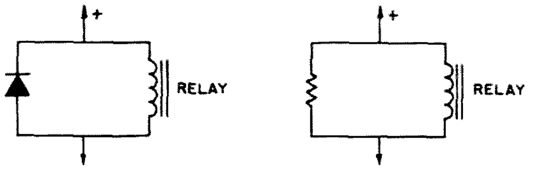

Fig. 3. See Text.

VY3 is the usual transmitter antenna changeover relay.

RY4 is another slugged type, but this time with the copper ring at the toe or top end —next the armature. This makes it slow to operate as well as to release. See **Fig. 2b.**

Finally, RY5 is the transmitter B-plus relay.

Modus operandi

S1, the PTT switch, activates RY1, and current is fed via the "A" contacts to RY2, which closes immediately as it is only slugged for delay on release. So RY3, the antenna change-over relay, is energised without any appreciable time lapse. Receiver input is grounded, and antenna switched to transmitter.

Current is also fed via the "C" contacts on RY1 to RY4, which is slugged to give a time delay in both operate and release modes. So here is there is a time lag before current is fed via the "B" contacts on RY1 to RY5—to turn on the transmitter B-plus.

In the reverse action, S1 is opened, RY1 de-energised, voltage removed from RY2, but —as this has a delayed release—it keeps its contacts closed for a short space of time. So current is still supplied to RY3, and the antenna remains switched to the transmitter for a little while.

Now, although RY4 is slugged and so has a delayed action, the supply of current to RY5 is via the contacts "b" on RY1. And these open immediately after S1 is opened, so the B-plus is removed from the transmitter before the antenna is switched over to the receiver. Result is safety, and long life to your expensive front-end transistors!

. . .G3KPO.

Report on the Drake R-4A Receiver and T-4X Transmitter

Fred W. Fetner, Jr. WB4EFA
1728 *Ebenport Road*
Rock Hill, S.C. 29730

After getting off to a bad start with an inexpensive receiver which proved to be unsatisfactory, I decided to purchase a really good receiver. For some time I studied the specifications of the available receivers but overlooked the Drake for some unknown reason. One day, I read the specifications of the Drake Receiver and was astonished by its many features. After much comparison with other receivers I found that I could find no other receiver at any price with all of the following features:

1. Permeability tuning
2. Transistorized VFO
3. Passband Tuning
4. Crystal lattice filter in first *if* stage
5. Highly selective and adjustable tuned circuits in 2nd *if* stage.
6. Noise blanker as standard (not optional) equipment (not merely a noise limiter)
7. 1 kHz tuning accuracy
8. Notch filter
9. Auxilary band coverage capabilities

I bought my R-4A in April 1967 and was immediately impressed by its good appearance which somehow is not done justice by the catalog pictures of it. I also noticed its extreme quietness. The stability is remarkable. No drift has ever been detected even from a cold start. My homemade CW crystal controlled transmitter has more drift than the R-4A. No retuning has ever been needed. The skirt selectivity is amazing with any normal S-9 signal more than 1 kHz away being inaudible. After using the receiver for a while I began to wonder if the unit was more selective than the standard communications receiver employing a sharp CW crystal filter. So I got such a receiver on loan and used it and found that while it had a very pronounced peak the skirt selectivity was not nearly as good as that of the R-4A and that overall the R-4A was vastly superior and more selective, and much easier to tune.

The Drake has passband tuning which makes it superior to any receiver which does not have this feature. This is an adjustable or tunable circuit in the 2nd *if* stage which may be tuned over a 6 kHz range. The receiver frequency is not changed by the passband tuning control, the control merely selects and peaks the desired frequency out of the 6 kHz wide signal which comes through the crystal filter in the first *if* stage. The lattice filter provides the immunization against cross modulation from nearby powerful stations, and the skirt selectivity and the passband tuning system provides the actual main selectivity which is adjustable from 4.8 kHz to .4 kHz in four steps. 2.4 kHz and 1.2 kHz is provided for SSB use. Upper or lower sideband selection is also made with the passband tuning control. The control can be used to select any one of several stations near the same frequency without having to move the main tuning knob. There is little chance of losing a signal on CW since once the station is heard, the main tuning can be left unmoved and the signal peaked by using the passband control. No variable BFO is used, and none needed, since after peaking one signal all further signals come in at the same audio pitch. By using the high selectivity, Effective T notch filter and switching to the opposite sideband, if necessary, it is rare indeed that a station cannot be copied through QRM. Many times my contacts have referred to QRM on their end and I have replied that they are 599 with no QRM. Some of this is due to the different locations, but most of it is due to the selectivity of the receiver.

The noise blanker eliminates most man-made type interferrence completely but has little effect upon static. Setting the T notch

filter slightly off to one side of the desired signal helps somewhat in copying under heavy static conditions.

Turning the passband control to the center position or slightly to one side of center makes weak CW signals come in stronger and for extreme QRM conditions setting the control toward the extreme right or left position increases the selectivity while making the receiver less sensitive. For SSB the 2.4 kHz position is provided and for extreme QRM conditions the 1.2 kHz position works wonders.

The main dial is marked in 25 kHz increments and a skirt on the main tuning knob is marked in 0 to 25 kHz increments. The claimed accuracy is within 1 kHz across the dial but I have found it to be better than claimed. The calibration holds within about 200 Hz from band to band. Resettability is perfect. No backlash or slack exists.

Drake T-4X

When I purchased the receiver I had no idea that I would ever get the matching transmitter. But after using the receiver for almost a year I was so impressed and pleased with it that I decided to get the T-4X. It has VOX, PTT, CW sidetone and operates at 200 watts on AM as well as SSB and CW. AGC is employed on SSB and eliminates overmodulation even though the gain might be turned to maximum. No TVI has been detected even to a portable TV sitting right next to the transmitter. It seems to pack quite a punch for 200 watts. I have received many 40 over S-9 reports and many people thought I must be using a linear. I am using a dipole mounted about 15 feet high.

The real beauty of the combination is its flexibility of frequency control. At the mere flip of one switch separate frequency control can be obtained or transceive operation can be selected with either the receiver or the transmitter controlling both units. One VFO can be left in the CW band and the other in the phone band and the proper VFO is selected instead of retuning across the band.

The extra VFO is very useful in finding a clear frequency while the other VFO is left set on the frequency of the person you are working at the moment.

Of course, if someone starts drifting you can switch to separate frequency control to stay with him with your receiver without altering the transmitted frequency.

A regular zero beat system is used for CW but for SSB a "canary" or warbling type of beat tone is heard. When the units are tuned to within 2 or 3 warbles per second, the separate units are tuned to within 2 or 3 Hz of the same frequency. This is much more accurate than the regular zero beat method normally used which might be in error by 100 Hz or more.

The new T-4XB and R-4B appear to use the same basic circuits with certain improvements such as: a 50 kHz calibrator for sub-band marking, and a newer and better crystal lattice filter in the transmitter for even better sideband suppression. They also have a new tuning knob and knob skirt or dial and a new chip resistant paint finish.

If you will compare I think you will agree that none of the competition can equal the Drake Line.

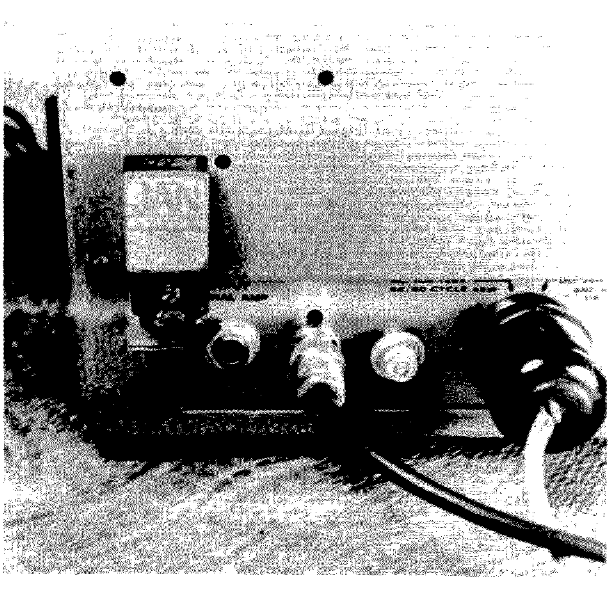
Operating Suggestions For The Two'er

E. H. Marriner W6BLZ
528 Colima Street
La Jolla, California

There have been numerous suggestions for improving the two meter Heathkit HW-30 transmitter-receiver also known as the Two'er. Here are some more suggestions.

In order to change crystal frequency it is necessary to remove the cabinet. The crystal originally is inside. A socket could be mounted on the front panel to remedy the situation, however, the long leads back to the original socket add so much capacity and inductance that the crystal may no longer oscillate. Some operators have solved the problem by cutting a square hole in the side of the cabinet. A better solution is to mount the crystal socket vertical at the back of the cabinet, and it does not take up much more space. A new .001 disk capacitor and a 22K 1 watt resistor will be needed because the new leads need to be slightly longer than the original components. To mount the crystal in the vertical position requires disk sanding a double type crystal socket down to the center hole. In other words do not cut the socket exactly in half. A number 41 drill hole is required through the side of the socket to fasten it to the back of the chassis. A dab of Armstrong cement will help the screw secure the socket in a solid position. Two tiny holes are now drilled through the chassis for the leads of the 22K and .001 mfd capacitor whose leads have been covered with Teflon type spaghetti insulation to prevent shorting of the leads to the chassis. To change crystals now only requires peering around the corner of the cabinet to pull the crystal out and to plug in another.



Mounting the crystal socket and the BNC coax socket.

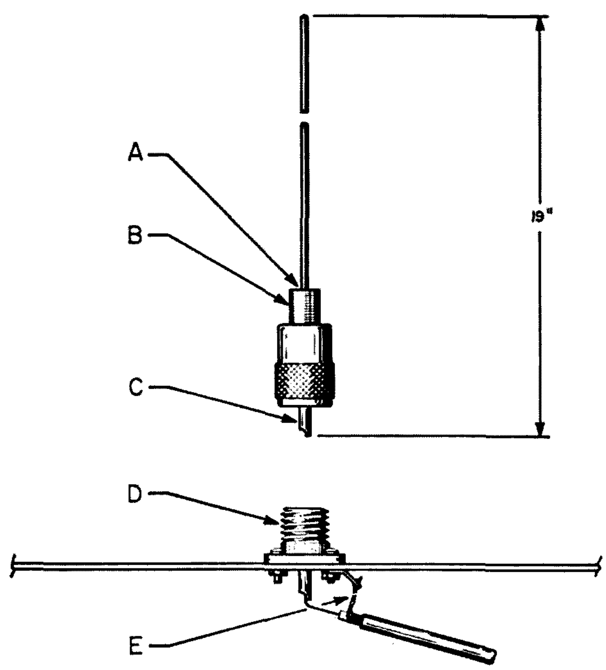


Fig. 1. Two meter antenna made from a type SO VHF coax plug.

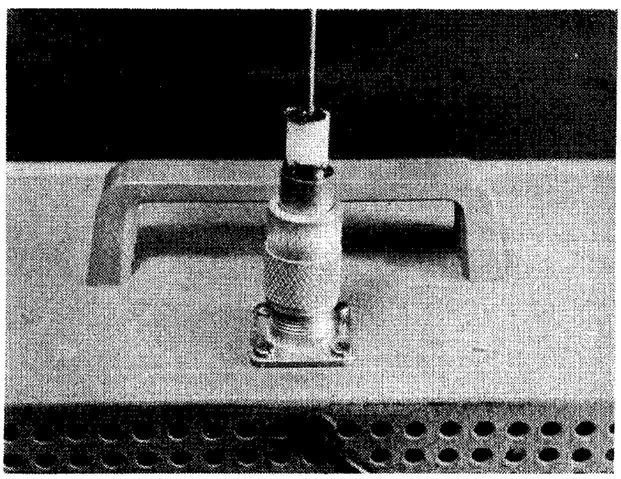
A. use a number 41 drill through the nylon center to accept the rod. B. 3/8x1" nylon slipped over rod after soldering. C. Brass rod pushed in and soldered here. D. Plug installed on top of the Two'er cabinet. E. Coax braid soldered to lug.

Another improvement to the Two'er is to replace the phono type *rf* output socket with

Frequency	Crystal
144.000	8000 kc/s
144.18	8010 kc/s
144.45	8025 kc/s
144.7	8040 kc/s
144.9	8050 kc/s
145.31	8073 kc/s
145.35	8075 kc/s
145.440	8080 kc/s
145.500	8083.3 kc/s
145.620	8090 kc/s
145.800	8100 kc/s
145.900	8106 kc/s
146.000	8111 kc/s
146.090	8116.7 kc/s
146.200	8225 kc/s
146.500	8140 kc/s
146.700	8150 kc/s
146.820	8156.6 kc/s
147.1	8173 kc/s
147.2	8175 kc/s
147.6	8200 kc/s
148.00	8227 kc/s

a BNC chassis mount type. This will make it easier to change the RG58/U antenna cable. To put in this fitting the hole will have to be enlarged to ⅜ inches and the fitting will push in and the nut can be fastened to the underside of the chassis.



Mounting the portable antenna on the Two'er cabinet.

For portable operation in the backyard or on the dining room table, a vertical 19 inch whip antenna can be made and mounted on top of the cabinet. (see **Fig. 1**) It is only necessary to punch a ⅝ inch hole on the top of the cabinet and then solder on a short piece of RG58/U, and push it out one of the vent holes at the back of the cabinet. Now attach a BNC type fitting to the short lead and push it in the new BNC chassis fitting. The antennas can be made from a piece of brazing rod which is pushed through a piece of nylon insulation and is later pushed down into the SO type fitting and cemented after the rod has been soldered to the plug pin.

Each time a new antenna is used on the set the final will have to be adjusted for maximum output a fact often overlooked by operators because the ceramic output capacitor is inside the cabinet. A small hole can be drilled on the side of the cabinet so that a tuning wand* can be inserted to tune the final amplifier while watching the 0-1 mA output meter plugged into the back of the cabinet.

While these suggestions may seem trivial, they may be of great help to the person not familiar with the two'er, and they certainly make operating of the two-er much easier.

Technical Aid Group

Please refer any questions of a technical nature to one of the following members of 73's Technical Aid Group. These are dedicated amateurs who really want to be of help and do so without compensation. Be sure to state your problem clearly and enclose a S.A.S.E. for a reply.

John Allen, K1FWF, high school student, 51 Pine Plain Road, Wellesley, Mass. 02181. HF and VHF antennas, VHF transmitters and converters, AM, SSB, product data, and surplus.

Bert Littlehale, WA1FXS, 47 Cranston Drive, Groton, Conn. 06340. Novice transceivers, test equipment and homebrew projects gone wrong.

Bob Groh WA2CKY, BSEE, 123 Anthony Street, Rochester, New York 14619. Specializes in VHF/UHF solid-state power amplifiers, but will be glad to make comments on any subject.

G. H. Krauss, WA2GFP, BSEE, MSEE, 70-15 175 Street, Flushing, New York 11365. Will answer any questions, dc to microwave, state-of-the-art in all areas of communications circuit design, analysis and use. Offers help in TV, AM, SSB, novice transmitter and receivers, VHF antennas and converters, receivers, semiconductors, test equipment, digital techniques and product data.

Charles Marvin W8WEM, 3112 Lastmer Road, RFD #1, Rock Creek, Ohio 44084. Will help with any general amateur problems.

Stix Borok WB2PFY, high school student, 209-25 18 Avenue, Bayside, New York 11360. Novice help.

Clyde Washburn K2SZC, 1170 Genesee Street, Building 3, Rochester, New York 14611, TV, AM, SSB, receivers, VHF converters semiconductors, test, general, product data.

Richard Tashner WB2TCC, high school student, 163-34 21 Road, Whitestone, New York 11357. General.

J. J. Marold WB2TZK, OI Division, USS Mansfield DD278, FPO San Francisco, California 96601. General.

Ira Kavaler, WA2ZIR, BSEE, 671 East 78 Street, Brooklyn, New York 11236. SSB transmitting, color TV, computer programming and systems, digital, radio and remote control, rf transmission lines, dipole design, audio amplifiers, linear and class C rf amplifiers.

Fred Moore, W3WZU, broadcast engineer, 4357 Buckfield Terrace, Trevose, Pa. 19047. Novice transmitters and receivers, HF and VHF antennas, VHF converters, receivers, AM, SSB, semiconductors, mobile test equipment, general, product data, pulse techniques, radio astronomy, bio-medical electronics.

Walter Simciak, W4HXP, BSEE, 1307 Baltimore Drive, Orlando, Florida 32810. AM, SSB, Novice transmitters and receivers, VHF converters, receivers, semiconductors, mobile, test-equipment, general.

James Venable K4YZE MS, LLB, LLM, 119 Yancey Drive, Marietta, Georgia. AM, SSB, novice gear, VHF, semiconductors, and test equipment.

J. Bradley K6HPR/4, BSEE, 3011 Fairmont Street, Falls Church, Virginia 22042 General.

Wayne Malone W4SRR BSEE, 8624 Sylvan Drive, Melbourne, Florida 32901. General.

Bruce Creighton WA5JVL, 8704 Belfast Street, New Orleans, Louisiana 70118. Novice help and general questions.

Douglas Jensen, W5OG/K4DAD, BA/BS, 706 Hwy 3 South, League City, Texas 77573. Digital techniques, digital and linear IC's and their applications.

Louis Frenzel W5TOM, BAS, 4822 Woodmont, Houston, Texas 77045. Electronic keyers, digital electronics, IC's commercial equipment and modifications, novice problems, filters and selectivity, audio.

George Daughters WB6AIG, BS, MS, 1613 Notre Dame Drive, Mountain View, California. Semiconductors, VHF converters, test equipment, general.

Glen H. Chapin, W6GBL, 3701 Trieste Drive, Carlsbad, Calif. 92008. HF and VHF antennas, novice transmitters and receivers, VHF converters, semiconductors, receivers AM, SSB, general, surplus.

Tom O'Hara W6ORG, 10253 East Nadine Temple City, California 91780. ATV, VHF converters, semiconductors, general questions.

Steve Diamond WB6UOV, college student, Post Office Box 1684, Oakland, California 94604. Repeaters and problems regarding legality of control methods. Also TV, novice transmitters and receivers, VHF antennas and converters, receivers, semiconductors, and product data.

Orris Grefsheim WA6UYD, 1427 West Park, Lodi, California 95240. TV, HF antennas, SSB, VHF antennas and converters receivers, semiconductors, and general questions.

Hugh Wells, W6WTU, BA, MA 1411 18th Street, Manhattan Beach, Calif. 90266. AM FM receivers, mobile test equipment, surplus, amateur repeaters, general.

Carl Miller WA6ZHT, 621 St. Francis Drive, Petaluma, Calif. 94952. Double sideband.

Howard Pyle W7OE, 3434—7th Avenue, S.E., Mercer Island, Washington 98040. Novice help.

PFC Grady Sexton Jr. RA11461755, WA1GTT/DL4, Hedmstedt Spt. Detachment, APO New York 09742. Help with current military gear, information from government Technical Manuals.

Sgt. Michael Hoff WA8TLX, Box 571, 6937th Comm. Gp., APO New York 09665. Help with all types of RTTY both commercial and military. Also data techniques. Covers conversion of military RTTY equipment.

Eduardo Noguera M. HK1NL, EE. RE, Post Office Box Aereo 774, Barranquilla, Columbia, South America, Antennas, transmission lines, past experience in tropical radio communications and maintenance, HF antennas, AM, transmitters and receivers, VHF antennas, test equipment and general amateur problems. Can answer questions in Spanish or English.

D. E. Hausman, VE3BUE, 54 Walter Street, Kitchener, Ontario, Canada. Would like primarily to help Canadians get their licenses. Would be able to help with Novice transmitters and receivers.

Frank M. Dick WA9JWL, 409 Chester St., Anderson, Indiana 46012. Will answer queries on RTTY, HF antennas, VHF antennas, VHF converters, semiconductors, mobile, general, and microwave.

Gary De Palma, WA2GCV/9, P.O. Box 1205, Evanston, Ill., 60204. Help with AM, Novice transmitters and receivers, VHF converters, semiconductors, test equipment, digital techniques and all general ham questions.

Arthur J. Prutzman K3DTL, 31 Maplewood, Dallas, Pennsylvania 18612. All phases of ham radio. Can assist with procurement of parts, diagrams, etc.

William G. Welsh W6DDB, 2814 Empire Ave., Burbank, Calif. 91504. Club licensing classes and Novice problems.

Ralph J. Irace, Jr., WA1GEK, 4 Fox Ridge Lane, Avon, Conn. 06001. Help with Novice transmitters and receivers and novice theory.

Iota Tau Kappa Radio Fraternity W7YG, Multnomah College, 1022 S.W. Salmon St., Portland. Oregon 92705. This group of radio amateurs will answer any technical questions in the field of electronics.

Ted Cohen W4UMF, BS, MS, PhD. 6631 Wakefield Drive, Apt. 708, Alexandria, Va. 22307. Amateur TV, both conventional and slow scan.

Roger Taylor K9ALD, BSEE, 2811 West Williams, Champaign, Illinois 61820. Antennas, transistors, general.

Michael Burns Jr. K9KOI, 700 East Virginia Avenue, Peoria, Illinois 61603. AM, SSB, receivers, transmitters, digital techniques, novice help, general.

Jim Jindrick WA9QYC, 801 Florence Avenue, Racine, Wisconsin 53402. Novice transmitters and receivers, general.

John Perhay WAØDGW/WAØRVE, RR #4 Owatonna, Minnesota 55060. AM, SSB, novice transmitters and receivers, HF receivers, VHF converters, semiconductors, mobile, product data, general. Has access to full specifications on almost all standard components presently catalogued by American manufacturers.

Ronald King K8OEY, Box 227, APO New York, New York 09240. AM, SSB, novice transmitters and receivers, HF receivers, RTTY, TV, test equipment, general.

Charlie Marnin W8WEM, 3112 Latimer Road, RFD 1, Rock Creek, Ohio 44084. General technical questions.

Michael Winter DJ4GA/W8, MSEE, 718 Plum Street, Miamisburg, Ohio 45342. HF antennas, AM, SSB, novice gear, semiconductors.

David D. Felt, WAØEYE, television engineer, 4406 Center Street, Omaha, Nebraska 68105. Integrated circuits, transistors. SCR's, audio and rf amplifiers, test equipment, television, AM, SSB, digital techniques, product data, surplus, general.

Tom Goez KØGFM, Hq Co USAMAC, Avionics Division, APO New York, New York 09028. HF antennas, mobile, airborne communications equipment, particularly Collins and Bendix gear, AM, FM, or SSB—HF, VHF, UHF, general.

Robert Scott, 3147 East Road, Grand Junction, Colorado 81501. Basic electronics, measurements. ■

MOVING?

Every day we get a handful of wrappers back from the post office with either a change of address on them or a note that the subscriber has moved and left no address. The magazines are thrown out and just the wrapper returned. Please don't expect us to send you another copy if you forget to let us know about your new address. And remember that in this day of the extra rapid computer it takes six weeks to make an address change instead of the few days it used to when we worked slowly and by hand.

The S.O.B.

(Sightless Operators Bridge)

Edward A. Lawrence WA5SWD/6
218 Haloid
Ridgecrest, Calif., 93555

If a sightless amateur could use a standard SWR bridge, he could make the proper adjustments to his antenna or matchbox to get maximum efficiency. But a blind operator cannot read a meter needle, so he is denied that valuable indication on any gear he may have. If the voltages are used to control an audio oscillator, they can be converted into a meaningful indication since most blind operators have very good hearing.

Here is a SWR bridge designed to indicate a null condition by the lowering in frequency of an audio tone. Only three diodes, three transistors, a UJT and a few other standard components are used. All semiconductors are silicon, for stability. Supply voltage is not critical, and the adjustments after assembly are few and easy.

Although I will describe this circuit as used in an SWR indicator, it could be used as a voltmeter with the addition of a fixed reference and appropriate multipliers.

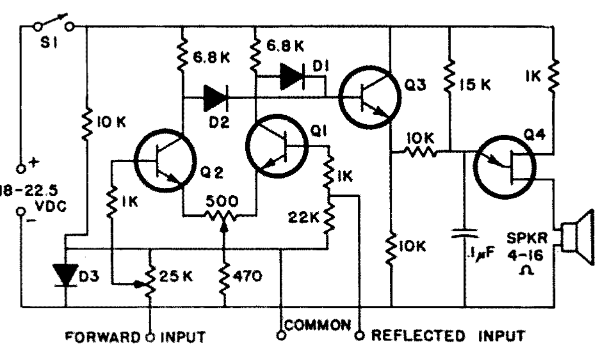

Fig. 1. Schematic diagram.

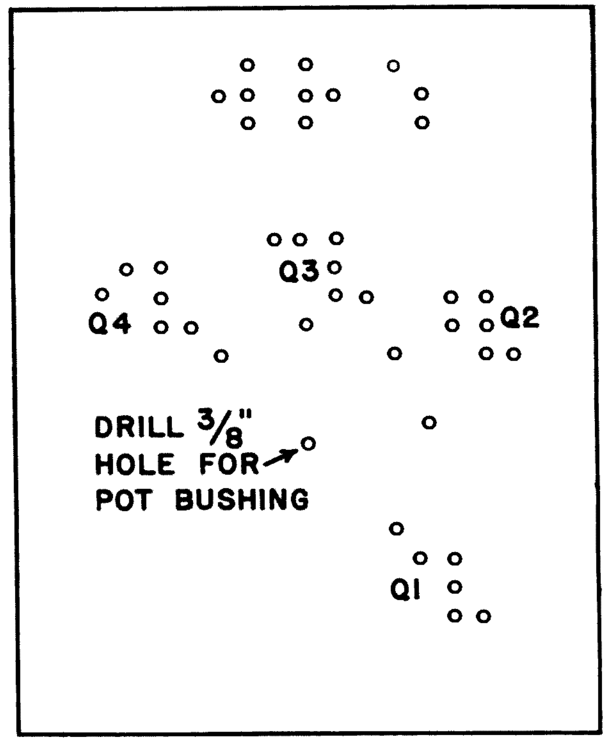

Fig. 2. Braille markings for front panel.

Refer to **Fig. 1**; you will see that transistors Q1 and Q2 make up a differential amplifier, which means both collectors will be at the same potential whenever the signal levels at the bases are equal. If they are not, then one collector will be higher than the other. The diodes D1 and D2 allow the base of the emitter follower Q3 to follow the higher collector. This puts the signal onto the 10 k resistor connected to the emitter of the UJT, and affects the time constant of the 15 k and the .1 µF capacitor. This varies the frequency of the UJT relaxation oscillator, which drives the speaker directly. The end result is that the audio frequency of the oscillator will rise if the signals at the inputs of the differential amplifier are not equal. Since the *reflected* voltage out of the SWR bridge is always lower than the *forward* voltage, we can find a position of the ratio pot where the amplifier is balanced. The position on the pot can be calibrated in Braille so the SWR can be read at the null position. Remember, the tone goes down at the null. Once the null is found, the tone will rise as the transmitter is peaked for maximum output.

With a good match (1.2:1 or so) a null can be detected with only three volts applied in against the reflected voltage, it would provide a sharper null with a poorer SWR. Naturally the null gets sharper with increased input. 20 vdc is about the maximum that should be applied to either input. If your SWR bridge puts out more than that, use a voltage divider to bring it down.

Note that the dc supply does not go to signal ground. This is so the signal can be

summed with the drop across D3 to prevent a 0.6 vdc dead zone. The signal voltages from the SWR bridge must be *positive* with respect to ground for this unit to work.

I said that the adjustments after assembly were few and easy. Well, one is few so here it is. Set the ratio pot to mid-range and apply a signal to top. About 6 vdc. Jumper the wiper of the ratio pot to the reflected input. This should force the bridge to balance. Measure between the collectors of Q1 and Q2. Adjust the 500 ohm pot until the meter reads zero. At this time, you should notice the audio tone dip in frequency as you reach the balanced condition. And that's all there is to it. One more check can be made at this time to insure proper operation. Short the base of Q3 to ground. This should cause the audio tone to drop to a low frequency. If it causes the tone to stop, change the 15 k resistor to a lower value.

To mark the dial in BRAILLE, use the pattern shown in **Fig. 2**. It is mirror image, so tape it to the inside of the chassis and punch through it. Use a small pointed punch and punch hard enough to raise the surface about 1/32 inch. Check to see that you can feel the pattern easily.

If possible, use a dual transistor for Q1 and Q2. It is nice but not absolutely necessary. Q4 is a 2N2160, but other UJT's will work as well. Almost any NPN Silicon transistor will work in this circuit, so don't be too fussy.

The UJT voltage controlled oscillator can also be used by itself in many applications to find a peak or dip in voltage. Some of the places that this could be applied are: Plate Current, Grid Drive, Output Power. Or the Face of the indicator could be marked to indicate Beam position if a pot were coupled to the rotor. I am sure that many more uses can be found, limited only by the ingenuity we can apply to the problems faced, which certainly isn't much of a limit.

. . . WA5SWD/6

RENEWAL CODE

The two numbers under your call on the address label are the expiration code. We have tried to make it simple. The first number is the month that we send you the last copy on your subscription and the second number is the year. 78 would be July 1968, for example.

Getting Your Higher Class License

Part X – Basic Rules and Units

All electronics—not just amateur radio —depends upon a knowledge of a few basic rules and units. The units are voltage, current, resistance, capacitance, inductance, and reactance, and the rules let us determine how these units affect each other in any particular circuit.

Important though these units and rules are, it is possible to be a good radio operator with only a slight knowledge of them. Because of this, questions concerning these basics are at a minimum on the Advanced Class examination—and also because of this, we have saved our discussion of these until this last installment. Now it's time to take a look at them.

The questions from the FCC study list which require a knowledge of these basic principles to answer are:

15. A resistor, capacitor, and inductor each have 100 ohms of resistance or reactance. What is the equivalent series impedance of these three elements?
38. A transformer with 115 volts applied across the primary terminals has a primary-to-secondary turns ratio of 10 to 1. If a 5-ohm load is connected to the transformer secondary, the reflected primary impedance is what? How much voltage appears across one half of the turns of the primary?
42. How do inductors combine in series and in parallel? Capacitors in series and parallel?

Following our usual practice, let's paraphrase these detailed questions into similar ones of broader scope to cover the whole range of the subject.

All three of the FCC questions deal with effects that occur only in ac circuits. We're assuming that you have some working knowledge of Ohm's Law—but this law applies only to dc circuits. For a starting question to explore, then, let's ask "How does ac differ from dc?".

One of the major differences between ac circuits and dc circuits is that in ac, we must deal with "reactance" as well as "resistance." For our question, let's determine "What is reactance?". The answers we'll find there will lead directly to another question (which takes us back to the FCC study list), "What is impedance?"

When we have a relatively clear understanding of reactance and impedance, we can move on to a question dealing directly with all three of the FCC questions: "How do impedances combine?" Finally, we'll cover all the principles involved in FCC question 38, by asking "What does a transformer do?"

Most discussions of these subjects tend to lean quite heavily on mathematics; engineering texts in particular seem invariably to rely on calculus to deal with reactance. That isn't really necessary, and we'll try to prove it by using nothing more complex than ordinary arithmetic—except for the minute amount of algebra necessary to present the various rules for calculation of results. None of them are any more complicated than Ohm's Law: $E = IR$.

All set? Let's get on with it.

How does ac differ from dc? The terms ac and dc are simply shorthand, as you probably know, for "alternating current" and "direct current". The major difference between these two types of electric current are that dc flows directly through the circuit, always going in the same direction, while ac changes its direction at fixed intervals, alternating between "forward" and "reverse" flow.

A flow of dc in any circuit has three

major characteristics which we use to describe it: its voltage, or the "pressure" forcing the current through the circuit; its current, the "amount" of electrical energy forced through the curcuit in a specified period of time; and its polarity, which tells the direction of flow.

These same three characteristics may be used to describe ac, but all of them have to be varied a bit when it's ac we are discussing. The voltage in an ac circuit is always changing; at one instant it may be zero, a fraction of a second later it may be 50 volts, a little later 100 volts, etc. Similarily, the current is also changing at all times from zero to some peak value and back. Finally, the polarity reverses every half-cycle; this is the key difference between ac and dc.

If we put an oscilloscope onto an ac circuit we can see directly the variations in voltage. We can also see that in any one circuit the voltage will never be more than some "peak" value. If we're looking at normal power-line ac, the voltage will swing from a negative peak through zero to a positive peak and back to zero on every cycle, and the peak values will always be the same.

We *could* use this "peak" value as our measure of voltage, and in some types of circuits we do. We could also use the full voltage swing from negative peak to positive peak as our measure—and again, some circuits *are* rated in terms of "peak to peak" voltage.

However, the normal "voltage" we talk about in an ac circuit is neither the peak nor the peak-to-peak value. Instead, we use something called "RMS" voltage which works out to be about 0.7071 times the "peak" voltage or 0.3535 times the "peak-to-peak" value. The "RMS" stands for "root mean square" and refers to the mathematical method by which the value was originally determined. For our purposes it's enough to know the ratios between RMS, peak, and peak-to-peak voltages.

The reason RMS values are used is simple: if we use this ratio for our voltage and do the same for our current, the resulting resistance values make Ohm's Law work for ac as well as for dc. If we use peak voltages, the power figures are wrong.

Another way of putting this is that the RMS values represent the *effective* dc equivalents of the ac figures. If a dc voltage of 120 volts and a dc current of ½ amp are applied to a light bulb a certain amount of light and heat are generated. If an ac voltage of 120 RMS volts is applied to that same light bulb, an RMS current of ½ amp will flow and the same amount of heat and light will result.

This takes care of *two* of our three basic characteristics—voltage and current—but the third, polarity, is a little less simple.

In an ac circuit, by definition, the polarity or direction of current flow is always changing. It would seem that we couldn't use this as a means of describing ac since any ac always involves both possible polarities.

And while it's true that we can't use it directly, we *can* use it indirectly, by using the *speed* at which it's changing. This we call "frequency"; frequency is measured in cycles per second (now known as Hertz; 1 Hz equals 1 cycle per second). One cycle is one *complete* swing of the ac from any positive peak back through zero and negative until zero is reached the third time. It's just as accurate to say a cycle is the swing from positive peak through zero to negative peak through zero back to positive peak. The important thing is that a cycle is one complete swing of the ac from any specified starting point until that starting point is reached again.

The three characteristics of ac, then, are voltage, current, and frequency. Voltage and current can be measured in either RMS, peak, or peak-to-peak values, but only the RMS values correspond directly to dc volts or amperes.

It's quite possible to have two different ac signals which have identical values of voltage, current, and frequency, but which still are not anything like "correspoonding" signals.

This comes about because both the ac signals are always changing. If both of them pass through zero, positive peak, and negative peak at exactly the same instant of time, then the two signals *do* correspond to each other just as would two dc signals of identical voltage, current, and polarity.

If, however, one of the signals passes through its *negative* peak at the same instant that the other passes through its *positive* peak, then the two are mirror images of each other even though they do both pass through zero at the same time. If we were to try to mix these two in the same

circuit, we would find that one cancelled out the other and we would have nothing left.

This is the same thing that would happen if we tried to put together two dc signals of identical voltage and current but opposite polarity; again, the two would cancel.

You can see that, with the two ac signals we're looking at, the only difference is the time relationship between the two. This time relationship between two ac signals of identical frequency is known as "phase", and is always a relative measurement. It is just as accurate to say that signal A is "ahead" of signal B as it is to say that signal B is "ahead" of signal A; the only way in which we can talk about phase is to decide that *one* signal is going to be our fixed reference point, and then say whether the other is "ahead" or "behind" that rather arbitrary reference.

Another important fact concerning this idea of phase is that it applies *only* to signals of identical frequency. If the two signals we're talking about are of different frequency, then even if they start in the same phase so that both reach positive peak at the same time, they cannot both reach the following negative peak at the same time. If they *did*, they would be of the same frequency. Being of different frequency, they take different amounts of time to go through a cycle.

The key thing to keep in mind in any discussion of phase is that the word really is a measure of *time* even though we talk about phase in terms of "degrees".

The reason that phase is measured in "degrees" is that a full cycle of ac is like a circle. Every point around the circle is a different point, and similarly every instant within the cycle of ac is a different instant. Once we have gone all the way around the circle, though, we can't tell the difference between the second trip and the two-hundredth time around—and similarly once we have examined an ac signal all the way through a single cycle, we can't tell the difference between the second and the two-hundredth succeeding cycle.

Since one full cycle is similar to one full trip around the rim of a circle, we call a cycle 360 degrees. A half-cycle then becomes 180 degrees, a quarter-cycle is 90 degrees, and so on.

For any signal of specific frequency, though, these "degrees" are actually time measurements. For instance, if our signal's frequency is 1000 cycles per second, then one full cycle takes 1/1000 second or 1000 microseconds. This makes 360° of phase equal to 1000 microseconds. A phase "lag" of 180° then equals a time delay of 500 microseconds, and a time interval of 10 microseconds equals 3.6° of phase angle.

If we double the signal frequency, to 2000 cycles per second, all the time values are cut in half but the phase degrees are not changed. Now 180° equals 250 microseconds, and 10 microseconds equals 7.2.

To sum up all of this, the major difference in description between ac and dc are that dc is measured in constant volts, constant current, and constant polarity, while ac is measured in terms of varying voltage, varying current, changing polarity at a known frequency of change, and, if two or more signals of identical frequency are involved, relative phase.

When the idea of phase can be applied —which is only when frequency is not changing—it corresponds more directly to dc's "polarity" than does frequency. For example, two dc signals of equal voltage and current but opposite polarity will cancel each other out. So will two ac signals of equal voltage, current, and frequency, but 180° out of phase with each other.

What is reactance? Now that we have the necessary words and ideas, we can take a look at this thing known as "reactance" which is found only in ac operation; there is no dc equivalent.

So far we have talked about relative phase between two ac signals, with the unspoken assumption that we were talking about two distinct signals—maybe even on different wires—each of which had its own voltage and current values.

Actually, in the world of ac, voltage and current don't necessarily bear the fixed relationship to each other that they do when it's dc we're involved with. In a single ac circuit, with only one "signal" in the usual sense of the word, we have to think of the *voltage* as one signal and the *current* of that same circuit as another, separate signal.

When the "two" signals we're examining are actually the voltage and current in a single circuit, then they must be of the same frequency, and the idea of "phase" is applicable.

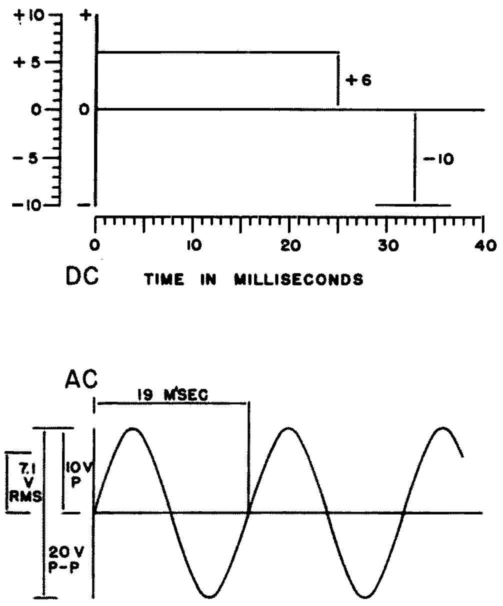

Fig. 1. Differences between dc and ac are shown by these illustrations which represent either current or voltage in a circuit. dc (A) is steady in the same direction, while ac (B) reverses direction at fixed frequency.

And like the two separate signals we examined a few paragraphs back, they can have any conceivable time relationship with each other.

For a start, let's assume that the two signals voltage and current are in perfect step with each other. The phase difference is 0°; when voltage is zero, so is current. When voltage is at positive peak, so is current. This is the "normal" case for an ac signal, and most descriptions of ac are based on this assumption.

However, it's possible for voltage and current to be out of phase. If they are out of phase with each other by 90 degrees, then when one is going through a peak value the other is zero. For example, if the current is 90° *ahead* of the voltage, then when voltage is at its positive peak value the current is zero. As voltage descends toward zero, the current value will be going towards its negative peak. When voltage reaches zero going negative, current is at the negative peak, and as voltage gets more negative the current is becoming less negative. When voltages reaches the negative peak, the current has again become zero going positive.

Now *power* in a dc circuit is simply the product of voltage times current, and in an ac circuit if both voltage and current are in phase is the product of RMS voltage times RMS current.

But when voltage and current are out of phase, the *power* available is *less* then the product of RMS voltage and RMS current. Staying with our current-ahead-by-90° example, when voltage is peak current is zero and power must also be zero. When current is peak; voltage is zero and power is still zero. During most of the cycle, current is peak; voltage is zero, and power is still zero. During most of the cycle, current is going one way and voltage is going the other, and again they tend to cancel out. The *only* time that any power is available in this situation is during that fraction of the cycle that voltage and current are both going the same way, and even then since both are far below their peak values the power is far less than would be expected.

If we shift things around so that voltage and current are a full 180° out of phase, then no power at all is available in the circuit although both voltage alone and current alone may be extremely large values.

This has the same effect as does *resistance* so far as available power in the circuit is concerned, but there's a major difference.

Resistance in a circuit converts the electrical energy into heat energy. Once that's done, the electrical energy is gone and we can't get it back.

The effect we're examining doesn't involve such a change. Instead, it merely changes the time relationship between voltage and current so that the energy is no longer available for use. If we should do something to change the time relationship back again, the energy would still be there for us to employ.

Because the effect is so similar to that of resistance, we measure it in the same electrical unit—ohms. Because it is *not* the same effect, we give it a different name, and this name is "reactance".

To put it simply, then, reactance, is just the measure of how much the time relationship between the voltage and current in a single ac circuit has been changed.

Since we can, if we use the *current* as the reference signal and consider the *voltage* as the signal which changes in time, move the voltage either ahead of or behind the current, the reactance can be either positive or negative. A negative reactance value means that the voltage has been delayed with respect to the current, so that the volt-

age is *behind* the current. A positive value of reactance means that the current has been delayed, so that the voltage is *ahead* of the current.

Two types of circuit elements have reactance, and the two have reactances of opposite types. The circuit elements are capacitors and inductors. The capacitor has negative reactance—which means merely that putting a capacitor in an ac circuit will cause the voltage to lag behind the current in that circuit. The inductor or coil has positive reactance; it causes the current to lag behind the voltage.

Frequently you'll meet the terms "capacitive reactance" and "inductive reactance." This just means that the net effect looks like either a capacitor or a coil, regardless of what is actually in the circuit.

Before we get away from this, let's take a small side trip and see why capacitors and coils have these effects.

First let's look at an empty or discharged capacitor and connect dc to it. At the instant of connection a large current will flow into the capacitor, charging it. As the capacitor charges it gains voltage of its own, and this voltage "bucks" the applied charging voltage. The current flow is determined by the effective charging voltage, and this effective voltage is equal to the actual voltage of the source minus the voltage on the capacitor.

The result is that as the capacitor changes, the charging current gets less and less. When the capacitor is fully charged, no current flows.

Now let's try that same thing with ac instead of dc for a source. Let's also assume that the ac is of fairly low frequency and the capacitor is of only moderate capacitance. Under these conditions the capacitor will have time to become fully charged before the ac reverses its polarity.

When the ac is applied, a large charge current starts to flow. As the capacitor's voltage bucks the applied voltage and current flow drops off, the applied ac voltage continues to change.

By the time the ac voltage reaches its peak value the capacitor has become fully charged and the current value is zero. So far the only difference between this and the action on dc is that with ac, the applied voltage was not steady but was always increasing.

When the ac voltage reaches its peak it begins to drop back toward zero. Now the

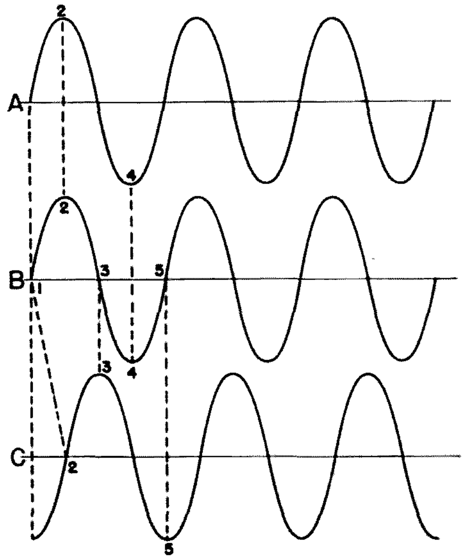

Fig. 2. "Phase" applies only to ac signals of identical frequency, and is a measure of their timing relative to one another. Here, for instance, signals A and B have 0° phase difference since they reach their peaks and cross zero at the same times. Signal C, however, is out of phase with either A or B since it peaks as they cross zero, and crosses zero when they peak.

capacitor is charged to a higher voltage than the applied voltage and it must begin discharging. It dumps out some charge, which becomes a current in the opposite direction.

As the ac voltage keeps dropping, the difference between the capacitor's voltage and the applied ac voltage gets larger and larger, so the current flow keeps getting larger and larger also in the reverse direction. When the ac applied voltage reaches zero, the discharge current is very high.

But as soon as the ac applied voltage goes through zero it changes direction, and now it's going the same way as the discharge current. This means that the applied voltage is now catching up with the discharge action and the voltage difference is getting smaller rather than larger. This in turn reduces the discharge current flow, so that the peak value of current occurs at the time voltage passes through zero.

As voltage moves toward the negative peak, the current flow continually decreases, and when voltage is at negative peak the capacitor's charge voltage and the applied voltage balance each other exactly. The resulting current flow is zero.

ac voltage then begins decreasing back toward zero, going now in the positive di-

rection. The capacitor is still charged to negative peak, so that the difference between applied voltage and charge voltage results in current flow into the capacitor in the positive direction again.

This process continues indefinitely; the current is always a quarter-cycle, or 90 degrees, ahead of the applied voltage. By definition, the reactance value when current leads voltage is negative.

If the capacitor is made larger, then it may not have enough time to become completely charged or discharged during any half-cycle of the ac signal. The current will still lead the voltage, but not necessariy by the full 90 degrees. If there is not enough time to fully charge the capacitor before the voltage polarity reverses, then the phase shift introduced by the capacitor will be less than 90 degrees. As we said earlier, reactance is a measure of how much the phase has been shifted—so that for signals of the same frequency a large capacitor has *less* reactance than a small one.

Since all this depends upon *time*, we can keep the capacitor size the same and change the signal's frequency to achieve the same result. If the frequency is increased then each cycle occupies less time, and again the reactance will be smaller.

Thus the reactance of any capacitor depends upon just two factors—the size of the capacitor and the frequency of the applied ac. If either of these factors goes up, the reactance goes down.

To calculate reactance for a capacitor, plug the two factors into the capacitive-reactance formula:

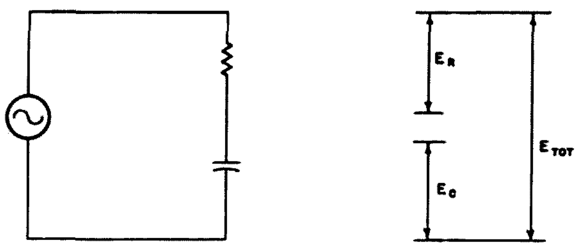

Fig. 3. This circuit illustrates differences between resistance and reactance in ac circuits. If resistance of resistor and reatance of capacitor are equal, voltages Er and Ec will be equal, but total supply voltage Etot will not be equal to the sum of the two. Instead, it will be less. See text and Fig. 4 for details of how this can be possible.

$$X_C = 1/6.28fC$$

In this formula, X_C stands for capacitive reactance, f is for frequency, and C is for capacitance. When the frequency is in cycles per second and the capacitance is in *farads*, the reactance comes out in ohms. However, farads are much too large a unit for practical capacitance values and we use microfarads instead. This changes the formula a little bit:

$$X_C = 159000/fC$$

The 159000 is a conversion constant which picks up the 6.28 of the earlier formula and also includes the million-to-one difference between farads and microfarads. In this formula, f is still in cycles per second but C is in microfarads. X_C is reactance in ohms.

When a coil is involved instead of a capacitor, the actions are similar but opposite.

When the applied ac voltage is zero nothing happens. As the voltage climbs toward its positive peak, current attempts to follow —but instead it is diverted by the coil into the *magnetic* field around the coil. So long as the voltage is climbing the current goes into the magnetic field instead of through the coil.

When the voltage stops climbing, at the positive peak, the magnetic field has its maximum energy. As the voltage starts to drop, it's not large enough to sustain the magnetic field at full energy and the stored current begins to be returned to the circuit. However, the voltage is dropping more rapidly than the energy can be released, and until the voltage drops to zero the current flow is continually increasing.

As the voltage passes through zero and starts going the opposite direction, a new current-storage effect begins to oppose the release of energy. The result is that current peaks at a voltage level of zero.

As the voltage moves from zero to its negative peak, the new current-storage effect and the previous current-release effect battle each other. The amount of current released continues getting smaller and smaller, and when the voltage reaches negative peak the two current effects finally cancel each other out to make net current flow zero.

Now as the voltage again climbs from its negative peak going positive, the effects re-

peat themselves with opposite polarity. The long-range effect is that the current lags behind the voltage—the opposite of the effect produced by a capacitor

As in a capacitor, the effect depends upon both the size of the coil (which determines the total amount of energy which it can store) and the frequency of the ac (which determines the time available for storage.) However, *inductive* reactance as in a coil goes up if either the coil size or the frequency goes up, while capacitive reactance went down.

To calculate inductive reactance, knowing the frequency of the ac signal and the inductance of the coil, use this formula:

$$Xl = 6.28fL$$

In this formula, f is in cycles per second (Hz) and L is in henries; Xl is in ohms. The formula is suitable in this form for power and audio frequencies. *rf* inductors are usually measured in microhenries; rather than changing the formula, simply use megacycles rather than cycles for frequency to use microhenries instead of henries for inductance, and Xl will still come out in ohms.

What is impedance? We have seen now how ac and dc differ, and we have defined "reactance" as a measure of the amount and direction by which the phase of the voltage in an ac circuit is shifted relative to the current in that same circuit.

Like resistances, reactances are measured in ohms, because like a resistance, a reactance reduces the amount of power available for use in the circuit. The major difference is that the resistance gets rid of the power completely by changing it to heat, while the reactance merely locks it up by changing time relationships.

Even though both are measured in ohms, reactance and resistance don't combine as directly as you might imagine. It's perfectly possible to have both in a circuit; in fact, it's impossible *not* to have both in any practical circuit. When both are present, the circuit behaves differently than it would with either alone. But it behaves in a manner which may at first appear a trifle strange.

Keep in mind that a resistance follows Ohm's Law for both dc and ac, provided only that ac voltage and current values are expressed in RMS terms. A reactance, on the other hand, appears on the surface to follow Ohm's Law—but its limitation of current (or voltage) is due to a time shift which it introduces.

Now take a look at the series circuit in **Fig. 3**, which contains both a resistor and a capacitor. We know that the capacitor has capacitive reactance; we'll assume that the frequency of the ac we're using and the size of the capacitor are such that this capacitive reactance is exactly equal to the resistance of the resistor.

Since both the resistor and capacitor are in series, all the current which goes through one must go through the other.

Going through the resistor, this current will produce a voltage drop determined by Ohm's Law, equal to the RMS current times the resistor value in ohms.

Going through the capacitor, this current determined by Ohm's Law—equal to the RMS current times the capacitive reactance in ohms.

This means that in this circuit, we have two separate voltage drops in series. It apparently stands to reason that each of them must account for half the total applied voltage; that is, if we put 115-VAC line power across the circuit we would expect to measure about 57.5 volts across each.

But that's not what happens. Instead, we'll measure about 81.6 volts across either the capacitor or the resistor.

So how can 81.6 volts in series with another 81.6 volts equal only 115 volts? The answer is, it all depends upon the timing.

These are ac voltages, remember, and an ac voltage is always changing from one peak value through zero to another peak. The only way 2+2 can equal 4 when it's ac voltages we're adding is if both voltages are "2" at the same time—and in this circuit, they're not.

Both voltages, you'll remember, resulted from current flow through the circuit. In the resistor, the voltage was exactly in phase with the current. However, in the capacitor, the voltage waveform lags 90° or one-quarter cycle *behind* the current.

That means that when Er, the voltage across the resistor, is at its positive peak, then Ex, the voltage across the capacitor, is only at zero, climbing toward positive. A quarter-cycle later, Er has reached zero on the downhill path and Ex has gotten to positive peak. The two are never in step with each other.

When both are going in the same direction, they add to and reinforce each other. When they're going in opposite directions, they tend to cancel out and only the larger survives in the total circuit. Fig. 4 shows this action by means of the waveforms of Er, Ex, and the resulting total-circuit voltage waveform.

The total voltage is the sum of the two individual voltages, and as you can see it is larger than either alone—but not twice as large.

In fact, with sine-wave voltages (which are the only kind we're talking about) the sum will be 1,414 times as large as either voltage alone, which makes the voltage across either element alone equal 0.707 times the total applied voltage, rather than half the total as we would expect.

We'll get back to this a little later, since it's the basis of one of the most important principles in radio. For now, let's continue down the road to find out "What is impedance?"

Take another look at **Fig. 4**, and this time notice the effect upon the timing of the various waveforms. The capacitive reactance shifted phase of the voltage a full 90° from that of the current while the resistor's phase shift was 0°. When the two voltages added together, the final phase shift was reduced to 45°.

When resistance and reactance are both present in a circuit, the phase shift is always less than 90°. Just how much less depends upon the ratio of resistance and reactance; in our example the two were equal so the phase shift was cut in half.

This combination of reactance and resistance in the same circuit is what's known as "impedance". Actually, "impedance" is the only thing you *can* have in an actual circuit. Pure resistance, like pure reactance, exists only in theory. Any resistor must have leads; the leads have at least a little inductance. This inductance puts a trace of inductive reactance into the circuit. Similarly, the insulation of a capacitor is never perfect; there's always at least some trace of leakage resistance through the insulation.

And even in theory, both pure resistance and pure reactance are merely special forms of the general idea "impedance". The best way to illustrate this is to look at the way engineers write down impedances.

Two ways are used; both have mathematic foundations but the math isn't important to us.

One way, based on the way a complex number is written, is to specify the impedance as the sum of pure resistance and pure reactance. If we represent the ohms of resistance by "A" and the ohms of reactance by "B", then the impedance becomes:

$$A + jB \text{ ohms.}$$

The "j" is from mathematics and indicates that the "B" is a reactance with 90° phase shift. The "jB" term may be either positive or negative depending upon the type of reactance involved.

The other way is to write the absolute impedance value and phase shift:

$$Z/\theta^{\circ} \text{ ohms.}$$

To use this way, "Z" must be calculated and so must θ; we'll stick with the "A + jB" method the rest of the way.

Now if we want to talk about a theoretically pure resistance, we can still describe it as an impedance of "A" ohms resistance and *zero* ohms of reactance, by writing "A + j0" as the impedance value.

Similarly, if we want to describe a pure reactance, it can be written "0 ±jB" ohms to indicate *zero* ohms of resistance but "B" ohms of reactance, with the + sign indicating that it's inductive or the − sign indicating capacitive.

Any time that neither A nor B is zero, you know that both resistance and reactance are present—and you're dealing with an impedance.

How do impedances combine? The reason we've gone into such detail about the "A" and "jB" method of describing impedances is that it makes all questions of combined impedances simple.

To calculate the impedance of a series circuit made up of several impedances (any of which may be "pure" resistances or reactances), all we have to do is total up the "A" values of each separately, do the same for the "jB" values, and write down the result.

Negative reactances cancel out corresponding amounts of positive reactance and vice versa.

For example, let's attack that study-list question about the 100-ohm resistor, capacitor, and inductor. First, let's describe the impedance of each of these elements sep-

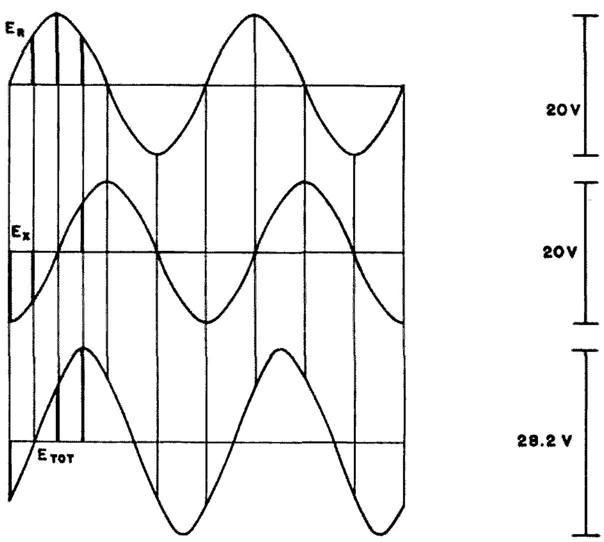

Fig. 4. Waveforms show timing differences between voltages across resistor and capacitor in circuit of Fig. 3. Total voltage always equals the sum of the instantaneous voltage values as indicated by the vertical matching lines. With 90° phase shift, peak of total is 1.41 times that of either part.

arately. The resistor would be 100 ± j0 ohms since it theoretically has no reactance. The capacitor would be 0 - j100 ohms since it's all reactance, and capacitive. And the inductor would be 0 − j100 ohms since it too is all reactance, but positive.

The total series impedance is then (100 + 0 +0) for the "A" side, plus (0 − 100 +100) or (0) for the "B" side, and we find quite directly that the effective circuit impedance is only 100 ohms resistive —or 100 ± j0 ohms.

So far as the effective impedance of the circuit is concerned, the capacitor and the inductor have cancelled each other out!

They're still there, though, and the current flowing through this series circuit must flow through each of the elements. The capacitor and the inductor won't have any effect upon the total current, so the only factor limiting current from the power source will be the 100-ohm resistance.

To keep the figures simple, lets assume that we have a 100-volt generator feeding a circuit like this. That makes the RMS current through the resistor 1 amp.

But that 1 ampere flows through the coil and the capacitor also, not through just the resistor, and it causes 100 volts to appear across the capacitor and another 100 volts across the inductor. These are voltages which can be measured with an ordinary VTVM.

What the meter won't show is that the voltage across the capacitor is 90° behind the current, and that across the inductor is 90° ahead. This totals up to a pair of voltages 180° out of phase with each other, and they cancel out so far as the external circuit is concerned.

With the values given in the FCC study question this may not seem like much—but let's try some different values and see how things shape up. Let's trim the resistance back to 1 ohm and leave the inductor and the capacitor at 100 ohms each. While we're at it, lets cut the voltage down to 100 volts RMS.

Our impedances now are 1 ± j0 ohms for the resistor, 0-j100 ohms for the capacitor, and 0±j100 ohms for the inductor. The total circuit impedance, then, is (1+0+0) ± j(0−100+100), or 1 ± j0 ohms. With 10 volts RMS applied, the current will be 10 amps RMS.

Note that the two reactances, being equal, have cancelled each other out just as before. But now we have 10 amps flowing through the circuit, so that the voltage developed across the capacitor will be 10 times 100 or 1000 volts RMS, 90° behind the current, and that across the inductor will also be 1000 volts RMS but 90° ahead of the current.

From the standpoint of the 10-volt power source, neither of these kilovolt levels exists. However, if we tap off just the voltage across either the coil or the capacitor—just the same way we would measure it with a meter—and feed it into an amplifier, we will actually get this 100-to-1 voltage step-up.

What's more, since reactance depends upon frequency, there's only one frequency at which any coil-capacitor pair has identical reactance. This frequency is known as the "resonant" frequency of the combination, and is the basis for all our tuned circuits.

We've already seen that any actual circuit must have both resistance and reactance; this means that we can never quite reach the ideal theoretical conditions we've been examining here. Reactive elements such as coils or capacitors, as well as combinations of these elements such as tuned cir-

cuits, are supposed to approach this ideal as closely as possible. They are rated by a "quality factor" usually known simply as "Q", which is the ratio of "energy stored" to "energy released" or more plainly, the ratio of *reactance* to *resistance* in the circuit.

For example, the FCC question uses values of 100 ohms for both resistance and reactance; the Q of this circuit is 100/100, or 1. Our modified version, though, had 100 ohms reactance and only one ohm resistance, for a ratio of 100/1 or a Q of 100.

The higher the Q of a reactive element, the more energy it will store. This is not always an advantage. Transmitter tank circuits, for example, must operate at relatively low Q in order to let the power be released to the antenna.

The same combination-of-impedances approach we have been examining throughout this section can be applied to the combining of similar impedances.

The key factor to remember is that impedances in series *add* their A and B values to each other, but impedances in parallel split the effects of their A and B values just as do resistors. The total resistance of R1, R2, and R3 in series is $(R1 + R2 + R3)$, but if the three are connected in parallel the effective value becomes $1/((1/R1) + (1/R2) + (1/R3))$

Similarly, three impedances $A1+jB1$, $A2+jB2$, and $A3+jB3$ in series have a total impedance of $(A1 + A2 + A3) + j(B1 + B2 + B3)$. In parallel, the picture becomes a bit more complicated since the value of $1/(A+jB)$ isn't so easy to figure directly. It comes out to be $(A-jB)/(A^2 + B^2)$, and when you start adding up a string of these, things get messy in a hurry.

It's actually easier to handle this kind of problem by ignoring "impedance" for a moment and going back to the values of inductance or capacitance involved.

When inductors are connected in series, their effects add up just as do those of resistors. In parallel, the effects are split just as are those of resistors. These statements are true *only* if the various inductors involved are not coupled to each other in any way; if they are, some transformer action gets into the picture and modifies the effects in an unpredictable manner.

Capacitors, on the other hand, behave oppositely—which we might expect since in all other respects they act as opposites to inductors. When capacitors are connected in parallel, their effects add up; in series, the effects are split.

To determine the impedance of a string of parallel-connected inductors or series-connected capacitors, then, you can simply figure up the effective inductance or capacitance by the parallel-resistor rule. Then plug this single value into the reactance formula to determine the effective reactance of the group.

What does a transformer do? The theory behind transformers usually is made to appear extremely complex, and it isn't helped a bit by the fact that we use these devices for both power transformation and signal transfer—with different theory for each application.

When we're talking about power transformers, we usually talk about voltage or current step-up or step-down, and sometimes about turns ratio.

When, on the other hand, we're talking about signal transformers, we almost invariably talk about "impedance matching".

Actually, the theoretical differences between a power transformer and a signal transformer are almost non-existent. What differences exist are detailed ones, concerning the frequency range, power loss in the wires, and the like.

The basic transformer itself could care less which job it's doing, because it does both in exactly the same way—by transforming *impedance*.

To see how this works, let's get used to thinking of power in "impedance" terms by looking at resistors instead. If you take a 120-ohm resistor and connect it to a 12-volt auto battery, it will permit the 12/120 ampere, or 1/10 amp, to flow. This 1/10 amp times 12 volts amounts to 1.2 watts. A 2-watt resistor could be used, but it would get rather warm.

If we use a 12-ohm resistor instead of 120 ohms, then 12/12 ampere—or 1 amp—of current will flow, and we will have 1 x 12 or 12 watts of power in the resistor. The point is that the voltage did not change—but by changing the resistance, we changed the amount of current taken from the battery and thus changed the amount of power we were using.

The point is that the voltage did not change—but by changing the resistance, we

changed the amount of current taken from the battery and thus changed the amount of power we were using.

Now a resistor is a special kind of impedance. Our first resistor had an impedance of 120 + j0 ohms, and the second had an impedance of 12+j0 ohms. Had we been using ac rather than dc the results would have been the same—reducing the impedance to 1/10 its original level while keeping voltage constant would have permitted 10 times the current to flow, or 10 times the power.

Had we left the resistor's value constant, but instead changed from a 12-volt battery to a 120-volt power supply to provide a 10-time increase in voltage, the power would have gone up by 100 even though impedance remained constant.

This happens because the current goes up right along with the voltage; while only 1/10 amp would flow at 12 volts for 1.2 watts, at 120 volts a full amp would flow. This is 10 times the voltage and another 10 times the current; the power increase is 10 x 10, or 100 times, for 120 watts.

Now a transformer consists, in its most basic form, of two coils which share the same magnetic core. When current flows through one of these two coils, it is accompanied by a magnetic field. The strength of the field depends both upon the strength of the current and upon the number of turns in the coil. This magnetic field (so long as it is changing) induces a corresponding current to flow in the second coil, and this induced current again depends upon the strength of the magnetic field and upon the number of turns in the coil.

Both coils, being coils, have inductance. Hence they have inductive reactance—and are both impedances, since the wire of which they are wound also has some resistance.

A well-designed transformer has little reactance or resistance of its own, but any *other* impedances in the circuit will reflect back to the transformer because they will affect current flow in the circuit. This will, in turn, affect current flow in one winding or the other of the transformer, and that it will influence the strength of the magnetic field which provides the transformer's main action.

One other factor, which we have already mentioned, also influences the transformer's action—the number of turns upon each coil. As it happens, the strength of the induced current (assuming that the strength of the magnetic field doesn't vary except as determined by the ac frequency) depends directly upon the number of turns in the coil. If a coil of 10 turns provides an induced current of 1 amp, then a 20-turn coil will provide twice as much or 2 amp. Similarly, the strength of the magnetic field depends directly upon the number of turns: if a 10-turn coil will induce a magnetic field of 1000 gauss (the unit of magnetic field strength), then a 20-turn coil carrying the same current will induce a 2000-gauss field.

The two windings in a transformer are called the "primary" and the "secondary". The primary is the winding carrying the original current which produces the magnetic field; the secondary is the winding in which the induced current produced by the field flows. Transformers may have many secondaries; most, though, have only one primary.

Since the number of turns on the primary determines the magnetic field strength with a given primary current, and the number on the secondary determines the induced current with a given magnetic field strength, the *ratio* "primary turns"/"secondary turns" gives us a direct indication of the current ratio to expect. The effects of the magnetic field, although indispensable to transformer operation, disappear from the scene so far as we are concerned.

Now let's back up a moment and look again at our resistor with varying voltages on it. When we boosted the voltage by 10 times, with fixed resistance, the current went up by 10 also.

Had we had any method of increasing current by 10 times, we would have found that the voltage went up accordingly. In either event, the power would have gone up by 100 times when either the voltage or the current was changed by a factor of 10, so long as the impedance (resistance) remained constant.

If we increased the current by 10 times but found it necessary to keep the *power* constant, the only way to do it would be to *decrease* the impedance by a factor of 100. Ten times the current, flowing through 1/100 the impedance, would result in 10/100 or 1/10 the voltage—and 1/10 the voltage

times 10 times the current would make the power come out at 1.

When we put a transformer with a 10-to-1 primary-to-secondary turns ratio into a circuit, the secondary current is 10 times as great as that in the primary as we saw before. But the transformer is *not* a power source; it cannot put any new power into the circuit. The total power, then, must remain constant. This means that the secondary voltage must be only 1/10 as great as that across the primary—and that the secondary impedance can be only 1/100 of that at the primary.

This is a general rule for all transformers; they transform *impedances*, and the impedance transformation is equal to the *square* of the turns ratio. When the impedance is changed, both voltage and current are also affected, and the transformation of *either* voltage or current is equal to the turns ratio alone (not squared).

A 10-to-1 transformer connected across a 115-volt AC power line, then, will produce an output voltage of 11.5 volts across its secondary. A 5-ohm load connected to the secondary will be reflected as 100 times 5 ohms, or 500 ohms, at the primary, and there it will draw 115/500 or 0.23 amps. The current set-up in this transformer is also 10 to 1, so 2.3 amps will flow in the secondary circuit. To check all this, 2.3 amps through 5 ohms should equal 11.5 volts—and it does.

If the primary is center-tapped, the turns ratio from half the primary to the secondary is only 5 to 1, so the impedance across either half of the primary is only 125 ohms rather than the 250-ohms you might expect. This is a fact about transformers which many persons find puzzling. So long as you think in terms of voltage and current, though, as we did in that previous paragraph, you'll come out okay. Across half the primary, we have half the 115-volt supply or 52.5 volts. We have, however, twice the normal primary current. This is because we have flowing in this winding the full primary current of 0.23 amps, and *also* an induced current of another 0.23 amps because of the current flow in the other half of the primary. With 0.46 amps and 52.5 volts, we find 52.5/0.46 or 125 ohms impedance.

Incidentally, realization of the fact that any transformer is an impedance-changing device makes it easy to find uses for iron in the junk box. Those surplus 400-cycle power transformers, for instance, come in very handy as modulation transformers. You can either calculate or measure the turns ratio by comparing primary and secondary voltages, and obtain the impedance transformation ratio by squaring the turns ratio. Many center-tapped high-voltage transformers work out nicely as push-pull audio transformers, for medium-power AM rigs.

In the case of a signal transformer, signals are applied to the primary. Their voltage and current are both changed by the turns ratio, and the transformed signals come out at the secondary to meet some "load" impedance. That load impedance, in turn, determines the actual amount of current which flows in the secondary circuit. No more current can be present than that determined by the load, and this is reflected back into the primary circuit. Thus our 10-to-1 transformer makes a 5-ohm load look like 500 ohms to the primary circuit. A transformer with a 30-to-1 turns ratio would make 5 ohms in its secondary look like 5 x 900 or 4500 ohms in the primary. Vacuum tubes require high-impedance loads, while most antenna or audio circuits operate at low impedance—so transformers are necessary in almost all stages.

Next Month. This winds up the Advanced-Class study course; about all that we haven't covered in it are the FCC regulations themselves, and there's no substitute there for reading the actual regulations. The key things to remember from them for the test are the frequency limits of the various bands, including the CW, phone, etc., sub-bands, the legal record requirements on logs, identification, and the like, and required operating procedures.

However, the response to this course has been so great that we're not stopping now. Quite a few of you, we suspect, will be interested in going beyond Advanced Class to the Extra Class ticket—so next month we'll dive into the Extra Class questions, with the same type of approach we've been using all year. Until then, good luck—and happy studying. ■

This completes the Advanced License course. The ten chapters in this course will soon be available in book form. ed.

Care and Feeding of a Ham Club

Carole Allen W5NQQ

Lafayette, La. 70501

Part VII — Operation Public Service

Unlike basket weaving and chess, amateur radio is a hobby that not only entertains and educates but comes through during disasters to provide emergency communication. When ice storms, fires, floods, tornadoes, and hurricanes strike, radio clubs are called on to go to bat, and members should know how to use their stations at such times. And there definitely is "know-how" involved. It's o.k. to give handle and QTH and drag out a signal report during a leisurely rag-chew, but when power lines are down and messages pile up, snappy, down-to-business procedures should be used to get the most said in the shortest time.

Although most hams realize the need to be prepared for emergency conditions, there may be a spat at a club meeting about how much time should be devoted to planning and drilling. If the members vote unanimously to participate in the AREC/RACES program (Amateur Radio Emergency Corps and Radio Amateur Civil Emergency Service), drills can be planned frequently. But should some members feel the club is meant to be "all-fun and no-work," then training will have to be sandwiched in with other activities or perhaps scheduled for a different evening.

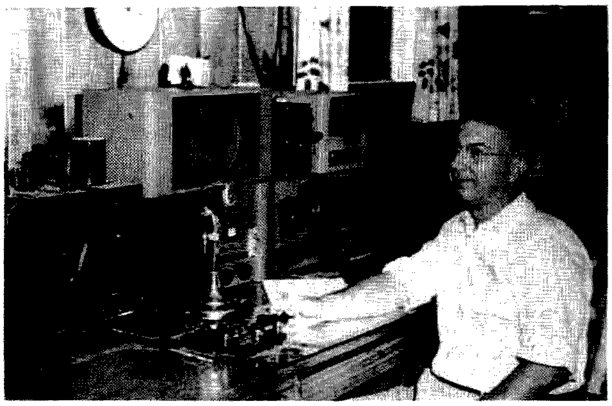
Many clubs have worked hard to convert buses and panel trucks into complete stations with transmitters on all bands, several operating positions, and even coffee bars. Any member of the Western Illinois Radio Club at Quincy will vouch for the value of a well-equipped bus after the April '60 flooding of the Mississippi.

Faced with a shortage of men to sandbag, the hams patrolled the levees with hand-carried transceivers and called workers to weak spots. The entire operation was coordinated by the local hams working through the privately-owned and equipped emergency bus operated by Ken Morrisson, WØTBI, of Hannibal, Missouri, just across the river. Your club may not be able to buy a bus, but purchasing a generator for emergency power should definitely be a goal.

The American Radio Relay League will gladly send a raft of material on AREC organization upon request. *QST* features a monthly column on AREC/RACES activities where you'll find spine-tingling adventures that really happen—stories of hams who have used their stations to evacuate flood victims, order medical supplies from around the world, find lost children, dispatch trains, and answer every imaginable call for help.

From time to time, newspaper headlines announce the name of an amateur or a club who have literally saved lives by knowing

A fully-equipped emergency truck or bus manned by local hams is an asset to any community and may be called on for communication and rescue missions. Shown above is the Ottawa, Illinois, team displaying their generator.



Francis Wentura, W9AEX, of Quincy, recalls the 1960 Mississippi floods when area hams literally saved the day with patrols along the levees.

what to do in a pinch. You and your club should make it a point to be ready, too.

Clubs on campus

Almost every college has a fine station and a lot of hams on campus, but club officers have to use dynamite to move anyone to a meeting. In the first place, students have little time for leisure activities, and, after all, they're usually in college, for schoolin' not foolin'. Nevertheless, a meeting a month and a ragchew now and then can provide a welcome change of pace for the busiest YL or OM.

As a hint for campus officers, get-togethers should be scheduled when the most folks can attend whether it's 10 A.M. Tuesday morning or 3 P.M. Saturday afternoon. At least one kind of "bait" is a club station licensed members can use for phone patches home and an occasional ragchew just to let off steam. If the equipment is ready to go at all times instead of being dismantled and strewn around the shack, all kinds of fun can be stirred up. Competing with other college clubs on Sweepstakes weekends and for DX contests and Field Days will probably bring in every ham enrolled.

A fixed base station can also spark a campus net or ragchewer's club creating between-meeting interest. Some of the most active young hams ever licensed lose their enthusiasm in radio during college years just because they're completely off the air. Campus radio clubs fight back by seeing to it that members operate at least once in a while. Unless the Dean has a rule on it, transceivers using short whip antennas can be plugged

into a dormitory outlet and fired up for local ragchews or merely "reading the mail."

A campus club takes the spirit of amateur radio plus hard work." Like a lot of other groups, most members are strangers in town, so strive to have a Club-away-from-home-Club.

Officers mustn't be afraid to try something new, and on the spur of the moment. A weekend field trip with portable gear or a CD drill with mobiles patrolling the campus doesn't have to be planned for months in advance. Impromptu parties and activities dreamed up when the work load lightens a bit will strengthen your club and probably call for a repeat later on. The Johns-Hopkins ARC holds an annual beach party they laughingly call an "orgy," and spring picnics are popular, too. A chance to get off-campus for a pre-June Field Day will be a big hit; in fact, just about any chance to get off-campus.

At a small school, the scarcity of hams may be a real snag. But there's an answer to this one, too. Unless you have time to recruit and train novices, take a look around and invite the non-college amateurs who live in the surrounding area. A ham is a ham no matter where he is, and most fellows and gals jump at the chance to visit a new club and become a member. Besides that, opening the campus club to locals can be the beginning of some fine new friendships.

Although we've been talking mostly about co-educational and men's colleges, let's not forget the girls. If you happen to be a licensed YL at Vassar, there's only one way to get gals to take up hamming—QSY your club to where the boys are!

73

Feedback can be either negative or positive, and so can your radio club. So far we've concentrated on ideas and plans your club *should* try, but, needless to say, there are *tabus* to avoid, too. Officers and members alike should work against *cliques* forming within the club; that is, the old time operators sticking together, the novices forming another group, and the technicians staying to themselves. Before long, the groups will start picking at one another and a first-class feud will break out and ruin the club's spirit. Novices can learn from the veterans, and technicians can often bring the 20 year men up to date on new developments. And, although the girls may not appreciate this comment, they should leave the "Have you heard about Helen" remarks at home for the good of the club.

Trying to force some idea on the members that they don't want is asking for trouble. All activities must be something the hams are interested in. A club should be organized around the hams' abilities, and all officers might make a mental note of this opinion. A club can be successful if the officers find out what the members want to do and follow it through regardless of how off-beat it may seem at first.

If your group doesn't seem to favor any particular activity, you can use a free hand in planning. The club which stands still soon disintegrates. Plan plenty of social events, nets, and projects. Take a tip and look over your own club's doings for the last year or so. Has everything been too much on-schedule with picnics held the same month and parties planned at the same place? If so, get out of the rut right now. Better to run the chance of a flop than let the club go stale. Stamp out boredom before it starts.

At the risk of resembling a "do-gooder," club officers should learn a code which isn't made up of dits and dahs. "The Amateur's Code" is a short bit of writing that reminds each ham to be gentlemanly, loyal, progressive, friendly, balanced, and patriotic, too. Anyone who lives up to these goals will be a credit to his hobby, to himself, and most certainly to a radio club.

The answers to such irritating questions as "Can't we do something interesting at our meetings?" and "Why don't we have as much fun as the Up-Hills Club?" may not be found in the Code, but it will sure help you hold your temper while you find it!

And now, although it's a lot easier said than done, Good Clubbing to you and 73!

. . . W5NQQ

YOUR CALL

Please check your address label and make sure that it is correct. In cases where no call letters have been furnished we have had to make one up. If you find that your label has an EE3*&* on it that means we don't know your call and would appreciate having it.

European VHF

Lee Grimes K7INU/DL5QN
Box 448 Co. A
USASA Field Station Berlin
APO N.Y. 09742

Except for moonbounce and satelite communications, one rarely hears or reads of the VHF activity on the European continent. I can recall only one or two not-so-recent articles in all of the three major amateur publications. How many even realize that there is really quite a bit of VHF activity—especially on two meters—in all of the eastern and western countries of Europe?

Before I was assigned to Berlin, I held the general misconception that European VHF-ers were few and far between, if they existed at all. I assumed that the two meter band would be as dead as it is in Idaho, where VHF stands for "very high frustrations". I had brought along an SB-34, thinking I'd work lots of DX and keep in touch with stateside. Instead, I spent a whole year with low power trying to squeeze a signal onto the overcrowded HF bands. Erecting a quad only seemed to increase the QRM. During a feeble moment I paid money for a linear and tried to smash holes in the band, but I never did find the Empty Frequency, so all I did was rum up the electric bill.

Last summer, during one of the giant weekend contests while trying to get a QSO in edgewise and lengthwise to no avail, I decided to throw in the towel and do something else. Out of desperation I even called a local friend on the landline. Unfortunately, it seems that in Berlin the telephones are so heavily bugged by Us and Them and practically everybody else, that signals are about 30 down in the mud and I could only give him about an S-3 report.

I finally sold out. About two or three months later a friend loaned me an ancient S-38 with a one nuvistor two meter converter. I was surprised at all the activity I found. Besides abundant local signals, on good nights using just a modified three element TV antenna, I logged several nearby countries: SM, OK, SP, and others. Most of the DX was heard on CW, with occasional SSB, and everything else as AM. FM is as rare as a 19¢ hamburger stand over there. Contests are frequent and are quite low key, and are therefore a lot of fun, even for a non-contester like me. There are club bulletins, code practice sessions, and ragchews as long as one wishes. After hearing all this, I was sold. A bit of timely operating with a modest set-up could net about 25 countries, and a lot of local friends during my stay overseas. It got me dreaming of what I could do with a Gonset GSB 2 SSB transceiver and a good 16 element collinear array.

Well, I got the Sidewinder, but it put me so far in the hole money-wise that I've had to settle for a five element bamboo and bent coat-hanger antenna (the BH-2, July '64 in 73). Now we hang our clothes on the floor until I can scare up some more hangers (wooden types this time, insists the XYL).

Since I'm now quite penniless, I begged the wonderful and most understanding wife for two bucks and purchased a keen 20 foot bamboo pole I had spotted at a local grass and flower factory. I then pounded a four inch diameter, five foot long water pipe into the ground and slipped the bamboo pole into the pipe—presto—a hand rotable 20 foot tower. Not really very high, but I wouldn't want to fall that far.

Having worked through my days off pummeling my "sky garage" into some kind of working order and locating it in the stratosphere, I had the thrill of my first VHF contact in Europe from Berlin—to Berlin. Alex, DC7AS, was kind enough to provide me with a critical signal report and even sent a taped recording of our QSO. I should receive more QSL's like that!

Language would be a big problem if it weren't for the fact that nearly all the amateurs of the western European countries use English as their second language. Most have taken it as required curriculum in grade and high schools, and I've found that most of the eastern European hams speak enough English to get by. In any case, it doesn't take very long to pick up enough of the local language (German, in my case) to use for short QSO's. Since I'm the only American ham in Berlin, almost everything I hear on the air is in German. It's no problem though, for as soon as I make a con-

tact the language switches to English. It won't be too long before I become proficient enough in German anyway.

The intention of this article is to help persuade some of the VHF-ers in the States who are coming to Europe, whether for vacation or by military assignment, to bring their equipment along—even just a Two-er—and apply for a license. Most European countries have signed a reciprocal licensing agreement, but it's best to check far in advance to see if it's really happening in the country or countries you wish to visit. VHF mobile is a bonus in Europe—signals are horizontally polarized, so bring a halo. For fixed stations, a four element beam is about the smallest practical antenna. With that, one should be able to work at least a dozen countries from anywhere in Europe. If you are able to work 10 states from your stateside station, you should be able to work at least that many countries over here. Where I am, in Berlin, there are more than 20 countries within range of 20 watts of SSB into a good beam. With aurora and meteors activity during the Fall, the band goes pretty wild!

Don't forget that the European two meter band is only two megs (144 to 146 MHz) wide. If you go rockbound, three crystals will do: 144.01 for CW; 144.5 for AM; and 135.425± 25 kHz for SSB. The last frequency is almost always monitored for any type signal, and is also one of the main DX frequencies.

I'll be here for quite a while to come, so if you ever visit Berlin, be sure to look me up. I've got cold tea, hot coffee, fine German beer, and I'd be glad to loan you my five element coat-hanger. I sure would like to hear some more Americans on two meters in Europe!

. . . DL5QN

Rambling On —

Jim Ashe W1EZT

If you have constructed a circuit and it doesn't work, maybe there was a mistake in the article. That does happen, and a good exercise before starting anything described in *any* magazine is to read slowly through the schematic looking for a mistake. Here are some examples of mistakes appearing in 73 Magazine.

Vackar VFO

In our October issue, "New Life for an Old Circuit" needs another look. See page 41. Blocking capacitor C9, between R7 and L4, was omitted from the schematic. A value of .01 mfd. will do nicely, but if you are using junk-box parts of uncertain value watch out for a capacitance that resonates with L4 at the operating frequency. A series-resonant circuit here could reflect a heavy load back through Q2 to the collector of Q1, with a possible reduction of stability.

This article also got off without a list of references for further reading. Try these suggestions for more information:

A Stable VFO for VHF or HF, by Del Crowell, 73, Nov. 1966.

The Vackar VFO, A Design and Try, by Gary B. Jordan, Electronic Engineer, Feb. 1968.

New Circuits Concepts for CB Transmitters, Motorola Application Report #84.

RCA Applications Guide ICE-228.

Credit for the original Vackar VFO design used in this article should have gone to Gary B. Jordon.

6 Meter Transmitter

Ken Robbins' article in the Sept. issue could use a bit of touching up. That is the 6-Meter Exciter schematic on page 53. Looking at the 2N3662 crystal oscillator, the 100K resistor extending downward from the transistor base terminal ought to be labeled 10K. The circuit may oscillate at 100K, but with small power output.

And looking at the two MPF105's which serve as a variable frequency oscillator and source follower, we note these are fed through a 330 ohm resistor. The circuit will work as shown, but with degraded stability.

Ken says this point (the junction of the two drain terminals and the 330 ohm resistor) should be held at a fixed voltage with an 8 volt 0.4 watt zener. The zener is bypassed with a 1 mfd. 10 volt capacitor to kill possible zener noise. Careful about polarity—the zener's diode arrow will point at the circuit, rather than at ground.

6 Meter Transceiver

Our September issue contains a nice article on building a solid-state Six Meter Transceiver. But the article was not as nice as it might have been, since it was short the following data on winding up the coils:

L1: 5 turns #26, ¼" long x ⅜" dia; 2 turn link on cold end.

L2: 5 turns #26, ¼" long x ⅜" dia; tap 2 turns from cold end, 2 turn link on cold end.

L3: 6 turns #18, 1" long x ½" dia; tap 1¼ turns from cold end, 2 turn link on cold end.

L4: 10 turns #26, ½" long x ¼" dia; tap 3 turns from cold end, 3 turn link on cold end.

L5: 75 turns #26, 2 layers, ⅜" dia; 3 turn link over middle of outer layer.

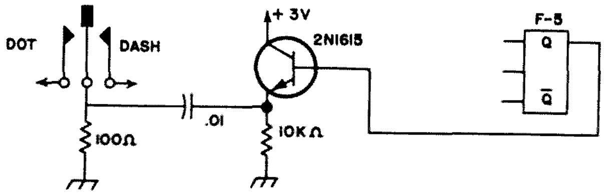
L6: 7 turns #26, ½" long x ¼" dia; tap 3 turns from cold end.

The Micro-Ultimatic

Sometimes we get letters on material printed some time ago, and here is an interesting one. It comes from Glen Winkler, WAØIFV. Glen writes,

"I just finished construction of "The Micro-Ultimatic" (June 1966 p. 6) and am delighted with the results. I etched two double-sided boards and soldered the IC's directly to the boards. Each board is 3½ x 2½ inches and easily holds all components. I have one correction and one suggestion to make. Fig. 7, page 13, should show a connection to "A" instead of "B." I could not achieve the dah-dit-dah-dit-etc pattern with both the dot and dash switches closed. The dot memory, dash memory etc., appeared to operate properly but a series of dashes occured when both the dot and dash switches were closed. The following modification corrected

this difficulty and essentially inhibits the input gates during shift register operation."



Now, do these mistakes have anything in common? Yes, there is an instructive similarity: they aren't subtle mistakes. A missing table, a wrong resistor value, a missing zener diode. Each of these is something visible to a skeptical eye. And a good scrutiny of an unfamiliar circuit is an excellent way to find weak spots in your theory background. Like calisthenics, the exercise tells you where extra work is needed.

Just enough room here for a couple hints to writers. Simple hints. How do you know if *73* would be interested in some idea you are thinking about? Simple. Read the last three issues very closely. There you can see what the editors have been thinking about, and against this perspective you can judge if your own idea might go over, or not. Remember that a part of the life of any magazine is change as well as continuation of present policy, so don't be afraid of new ideas. That's no promise, though. To paraphrase the old woodsman, if you've never had an article bounce you haven't written anything.

. . . W1EZT

(*W2NSD/1 from pg.* 4)

How about a channel where they can find compatriots?

Car buffs get a great kick out of discussing the new models, the merits of various sports cars, rallying, engines, and even the Mercedes 190D. Couldn't we set up a channel where these blighted creatures could congregate and lament over the sad developments in Detroit?

Our bands are already overcrowded, so where could we possibly put a bunch of new nets? It might be worth while to try 20M since most of the contacts there are two-way at present and the establishment of roundtables would permit many times the occupancy of the frequencies if the stations were netted.

As a starter let's try the following channelation of our interests. Undoubtedly I have neglected to think of a large number of widespread groupings, but let's get started anyway with this and work it from there.

14250	DXing
252	Religious
254	Girls
256	Traveling
258	Hunting-Fishing-Diving
260	Stamps-coins
262	Photography
264	Astronomy
266	Animals
268	Boats
270	Spectator sports
272	Cars
274	Golf-skiing-skating
276	Occult
278	Doctors-lawyers
280	Flying
282	Books
284	Clubs: Masons-Rotary-etc.
286	Boy Scouts
288	Languages
290	Stock Market
292	VFH-moonbounce-scatter
294	CD, RACES, etc.
296	Ham TV, RTTY, FAX, FM
298	Arts: music, painting
14300	UFO Net

The DX'ers should, I suspect, be first. It might just be helpful for DXing to have a channel to check for latest news and QTH's. It is a lot more fun to hook something rare if you have an opportunity to tell the other fellows about it and offer, solicitously, to help them get through as you did.

We have around the world quite a number of missionaries and padres who are active on our bands. I know that they particularly enjoy being able to contact each other and a channel on 252 should help them out. Of course the DXers in the next channel will keep their ear peeled for some of the rarer ones such as 9N1MM and 9X5GG.

Frankly I am not at all sure what can be discussed as far as girls are concerned, but I do know that they are of great interest to many amateurs and every time I have proposed this channel idea to a radio club there has been a demand for a girl channel. So be it.

If you have any interest of your own that doesn't seem to fit the list and which you feel should be represented, drop a line and we'll try and set up a special time or day for it on one of the channels that seems to have less activity than the others.

Let's give this a try and see if it develops into anything of value. Dissidents can get together on 14302 and coordinate.

. . . Wayne

Letters

Dear 73,

Kagnew Station Amateur Radio Club (ET3USA) is a small club—mostly military personnel—with a very limited treasury. At present we can barely afford the cost of printing QSLs and mailing logs to our QSL manager, plus the other costs necessary to keep the club going.

We regret we must ask for S.A.S.E. or IRC from all hams desiring QSLs. Please do not QSL direct to us. VE3TG has all logs and QSL cards.

We are trying to keep the station on the air as much as possible despite difficulties. All equipment here is owned by individuals and it looks as if we'll lose the beam we're using when the owner returns to the States in December.

ET3USA—Mrs. Deane Lindsay
W4EJQ—Secretary

Dear Wayne,

I just received my November issue of 73. I'd like to offer my compliments to you and your staff for an excellent cover. I don't know who your art makeup person is, but you're not paying him (or her) enough. The October cover was also just great. Please accept my congratulations.

I read your column "de W2NSD/1." You ask that anyone hearing "self righteous policement" to tell them that "Wayne Green says that he is sick and needs immediate mental treatment . . . "

I am so sorry to hear that you are suffering from some kind of mental illness problem. Would you please accept the enclosed dollar? I sincerely hope it will help toward your rapid recovery, because I hate to see anyone suffer.

A. Wilson W6NIF
San Diego, Calif.

Thanks a meg for the dollar. I took it right down to the local psychiatrist and invested in two minutes of intensive first class therapy. You will be happy to know that I have been pronounced completely cured and that all the thanks goes to you. Wayne.

Dear Madame,

Following the publication of my article "Burn Prevention" in the July issue of 73, I had several inquiries about the German soldering pistol pictured therein. The pistol, called the Sprint, is made by Europe's foremost manufacturer of soldering equipment, ERSA Ernst Sachs K.G., 6980 Wertheim am Main, Postfach 66, West Germany. The unit, because it does not use a conventional transformer as in other fast-heating irons, weighs less than half a pound and still heats up to about 100 watts in 10 seconds. Cost is about $8 plus postage.

D. E. Hausman VE3BUE
Ontario, Canada

Dear 73,

Your very good Advanced Class study guide articles are wonderful. Well written in common sense terms. The writer is easy to understand. I've read a lot of radio articles, but these are just great. Thanks much.

E. Schaldack WA9QQV
Chicago, Ill.

To the 73 Gang,

Just so my conscience is free and I get a good night's sleep, I felt obligated to write you regarding the fine magazine. Some time ago, I thought I'd drop the thing. Then you started the Advance Class License Course, which is, by itself, worth the price of the magazine. I like the "Editorial Liberties" by Kayla . . . if there is something outstanding about the publication, it is the "personal" feeling as though you were among friends. Best wishes for continued success.

C. E. Shaffer WA9VRK
Plymouth, Indiana

These are just two of the hundreds of letters which have come from readers in response to the study course. The Advanced course will be completed with this issue. We will immediately have it put in book form. Beginning with the February issue, we begin the Extra preparation.

HAM AUCTION, Feb. 16, 14th Annual by Toledo Mobile Radio Ass'n, at the Lucas County Recreation Center, 2901 Key St., Maumee, Ohio. $1.00 Registration, open table sales, map and further info. write Ron W8STA, 1939 Cone, Toledo, Ohio 43606.

WANTED: Opportunity to quote your needs. 30 years a ham dealer. Collins, Drake, Swan, all others. $20,000.00 inventory used gear. Electronic Distributors, 1960 Peck, Muskegon, Michigan 49441.

TEST EQUIPMENT WANTED: Any equipment made by Hewlett-Packard, Tektronix, General Radio, Stoddart, Measurements, Boonton. Also military types with URM-( ), TS-( ), SG-( ) and similar nomenclatures. Waveguide and coaxial components also needed. Please send accurate description of what you have to sell and its condition to Tucker Electronics Company, Box 1050, Garland, TX. 75040.

ESTATE LIQUIDATION SALE: Johnson Invader with Johnson low loss filter, $75.00; Heath HW-30 with microphone and instruction, $30.00; Heath IM-11 VTVM, $30.00; Heath IT-12 signal tracer, $15.00; RCA Voltohmyst Model WA65A (battery), $25.00; Waters Protax model 335 coax switch, $8.00; Barker-Williamson model 350 coax switch, $5.00; Signal Corps Bug key type J-36, $8.00; (4) new Eimax 7203/4CX250B tubes, $20.00 each; Ameco VHF model CN converter with model PS-1 power supply, $25.00. Arthur W. Lee, Rte #1, Box 23A, North Monmouth, Maine 04265. Tel: 207-933-2869.

SELL: SX-130 still in original box, won at a hamfest. Best offer over $125.00. Tom Hentz, WA9MCB, Room 326, Thomas Jefferson Hall, Rolla, Mo. 65401.

HEATH GC1-A receiver, XP-2 supply. $75. Heath HW-30 two meter transceiver, $35. Both with manuals. You pay shipping. W8ICY, 639 Lake Ave., Ironwood, Mich. 49938.

HEY, THERE!!!! YOU WITH ALL THAT ELECTRONIC GEAR IN YOUR SHACK!

Don't clutter up your home with all that stuff! Better to clutter up our warehouse — and get paid in the bargain! Don't waste time asking us for prices. ***Tell us exactly what you want*** for your Gen Radio, H-P, Tektronix, ARC. GRC, TED, PRC, VRC, ARN, URR, APN and other military/commercial gear. Write Today!

Editorial Liberties

They say "Imitation is the sincerest form of flattery". Apparently, one of the other magazines likes our cover format and copied it for their December issue. However, the advertisers must be delighted that their Xmas ads arrived on the scene after Christmas!

The illness which seems to have hit amateur radio recently is disturbing, to say the least. We hear obscene language (and I don't mean an occasional "damn" or "hell"), music, tape recordings, and a multitude of violations of both amateur rules and *just plain ethics.*

These are sick people! Incentive licensing is not the answer to this kind of problem. Personality defects can't be cured by knowing more about electronics, or being able to copy faster CW. There must be a form of screening for new hams. Obviously, FCC can't have a Psychologist in each office to decide whether a potential ham is going to create problems on the bands.

The thought occurs to us that perhaps the ham club could participate in the decision.

What would happen if a potential ham was required to have character references from a minimum of three other amateurs before he was permitted to take the exam? Taking it a step further, these references would be checked against the OO files at ARRL, to see if the references themselves were clean. If all seems in order, ARRL would recommend that the applicant be allowed to take the exam. If not, the request would be denied.

Even with Incentive Licensing, we make it entirely too easy to obtain a ham ticket, and very hard to lose it. FCC does not have sufficient personnel to monitor the amateur bands with any degree of efficiency. We are pretty much left to police our own bands and unless FCC receives a complaint, they don't take action. The ARRL Official Observer system is a good one, but has no real authority for action.

The ham clubs have been complaining for a few years that interest has been waning. Here might be the opportunity to give the club a real purpose. I think it might be a good thing to have every ARRL OO report be directed to the attention of a committee of the nearest affiliated local ham club for investigation. If the ham in question has a bad record with his local hams, ARRL could then recommend that FCC take action. We have a lot of housecleaning to do in our ranks.

It was once said, "Let he who is without sin cast the first stone." I have, and I'm sure most of us, have, on occasion, violated some of the rules. I once, while mobile, called CQ out of the band. We all, at some time or other, inadvertently, make mistakes. These isolated violations would not need to be included. However, where deliberate infractions of the regulations were involved, a hearing would be called by the local club. The results of this hearing would be forwarded to ARRL and FCC.

This month, I have taken the liberty of devoting a good portion of 73 to an article on Nikola Tesla. If this name means nothing to you, you would be well advised to read the article. Tesla's AC theory probably advanced the state of the art of electricity and electronics by at least twenty years. This article, lengthy as it is, tells only a part of the story. The reference list which follows, is one worthy of attention.

Also, this issue begins the Extra Class theory course. This follows the same format as the Advanced theory which has run in 73 for the past year. Apparently people *do* want to learn, rather than memorize. The response to this series is overwhelming! We will continue to devote space to tutorial articles as long as the demand is present. Maybe I'm wrong, but it seems to me the role of the ham magazine is not just "How to do it," but "Why it happens."

. . . Kayla—W1EMV

.....de W2NSD/1

The proof of the pudding is in the eating, if I may coin a phrase, and the proof of the value of incentive licensing is in the results that it brings to amateur radio. The incentive licensing rules were announced over a year ago and there certainly has been time enough for a pattern of response to the new rules to emerge.

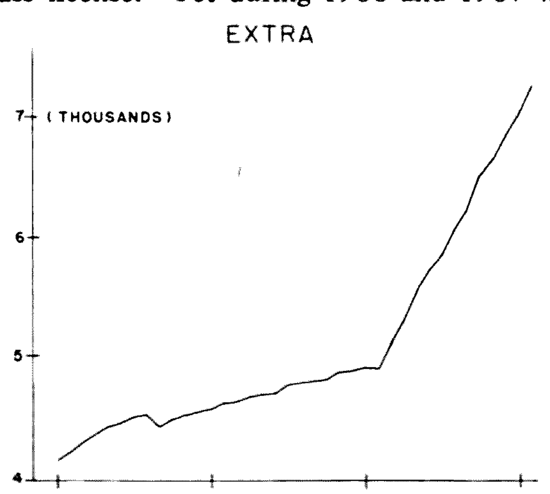
The new allocations for the Extra Class license came as a shattering blow to most DX hunters and contest fans. With the bottom 25 kHz now the exclusive Extra Class country this meant that virtually all of the DX hunting grounds were out of bounds for the other classes. The letters column in QST gave clear evidence that the amateur reaction to this was one of enthusiasm and determination. Everyone was buckling down and going to pass the new license exams.

Now that the facts are in we can see that the new licenses were met with massive apathy and resignation. There is little sign of any enthusiasm. Let's take a close look at the curve of the FCC released license figures and see what has happened.

As early as 1963, when the ARRL central Committee started the incentive licensing ball rolling, it was obvious that there were going to be some advantages to having the Extra Class license. Yet during 1966 and 1967 we see the number of EC's growing at about 500 a year, with a total of only 5000 at the end of 1967; many grandfathered into the license. Then, with the release of the new allocations, the curve changed and some 2000 new EC licenses were issued during 1968. This is about 1500 over the normal growth of the license, or about ½ of 1% of the 260,000 licensed amateurs.

It would be hard to envision a more devestating rejection. Amateur radio has flatly turned thumbs down on incentive licensing so far. Now that the new allocations have actually gone into effect we may see more of a rush for the EC license. Let's hope so, because our EC bands are just sitting there largely unused except for the DX stations now and our experience is that while nature abhors a vacuum, the commercials love it and are quick to fill in any blank spots we leave in our bands. And once in, it is almost impossible to get them back out again.

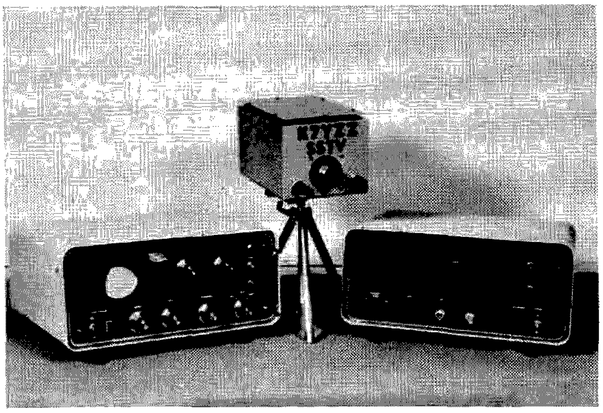
Why has the Extra Class license been turned down by the amateurs so far? The letters we receive indicate that most amateurs are put off at having to take what seems to them to be a professional exam for an amateur license. The theory part of the exam is quite comparable to the theory part of the First Phone Commercial License exam and the 20 wpm code test also seems "com-



(More of this on page 77)

A Fast-Scan Vidicon In The Slow-Scan TV Camera

Louis I. Hutton K7YZZ
12235 SE 62nd St.
Bellevue, Wash. 98004



With the successful construction of the Slow-Scan TV (SSTV) Picture Generator described in 73 magazine,[1] I decided to try my hand at building a SSTV Vidicon camera. I had previously built a conventional TV Vidicon camera of the type described in ATV Anthology.[2] I soon found that Slow-Scan Vidicons are expensive and scarce on the surplus market. Since I am not able to locate an available economical source of this type of Vidicon I decided to try to use a fast-scan Vidicon in the slow-scan mode. The camera described in this article is based on the design by Macdonald WAØNLQ,[3] but incorporates extensive circuit redesign of the video amplifier to permit the use of a standard fast-scan Vidicon operating in the shutterless slow-scan mode. The camera consists of two units, one the camera head, and the other the power supply, sweep circuits and sub-carrier modulator/oscillator.

[1] "A Slow-Scan TV Picture Generator", K7YZZ, 73, October 1967.
[2] "ATV Anthology", 73.
[3] "A Slow-Scan Vidicon Camera", Macdonald, QST, June, July, August 1965.

Camera head

To minimize stray magnetic field pickup the Vidicon, deflection coil assembly, 10 kHz video amplifier and detector were mounted in a steel cabinet 5" x 6" x 9". The shutter mechanism was omitted and a spacer made from sheet brass was installed between the cabinet front panel and the focus coil to provide the proper focus distance (25mm in my camera) between the lens and the face of the Vidicon. A fixed focus 16mm lens, Bausch and Lomb F2.7 to F16 - FL 25mm, was mounted to the front of the camera head. This lens was purchased from Burstein-Applebee and is their part number 61A78 in the 1967 catalog. The "Beam", "Video", and power plug are mounted on the rear of the camera head. The box lid is spaced one quarter inch from the box by metal standoffs to provide adequate cooling.

Comparing the circuit diagram of the camera head with the circuit of the Macdonald SSTV camera the reader will note the change of V13 and V14 to more common tube types and the addition of a tuned circuit to limit the bandwidth of the

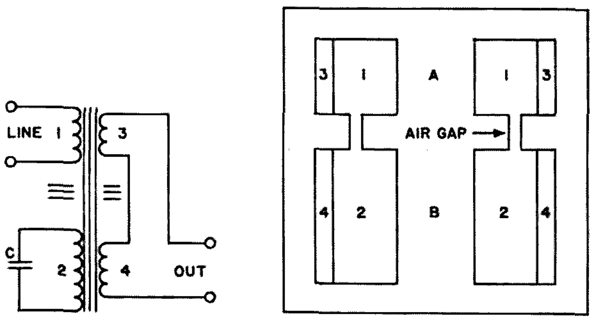


Fig. 1. Driving and control circuits mounted in the camera box.

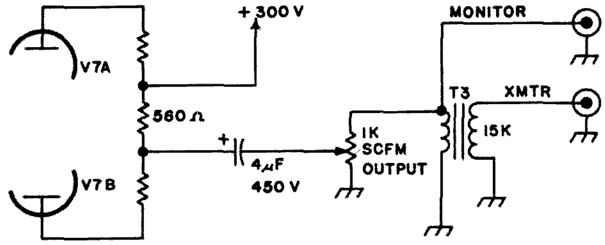

Fig. 2. Audio output control circuit.

10 kHz video amplifier. Several other component values were changed to optimize the new amplifier design.

The deflection yoke and focus coil assembly were handmade. Information on the techniques of making Vidicon deflection components may be found in the ATV Anthology. The focus coil was wound with #32 wire and has a dc resistance of 420 ohms.

Due to the lower vertical and horizontal sweep frequencies used in SSTV the deflection coils contain many more turns of wire than those used in fast-scan TV. The vertical deflection coils series dc resistance is 360 ohms, using a coil form window spaced of 11⁄16" x ¾" x .050" thick, with #36 wire. The horizontal deflection coils series dc resistance is 270 ohms, using a coil form window spacer of 1⅟16" x ¾" x .035" thick, with #36 wire. For those individuals not interested in winding their own coils, a kit of prefabricated deflection components for SSTV cameras may be purchased from ATV Research advertised in 73 magazine.

Main chassis

The remaining portions of the SSTV camera were built on a hand formed chassis housed in a Heath cabinet. The shutter control circuitry (V8a and V8b of the QST schematic) may be deleted if the builder does not plan to acquire the 7290 SSTV Vidicon. The 1200 Hz phase setter (V15) was also deleted as suggested by Macdonald. A 1000 ohm potentiometer was added to control SCFM audio output (Fig. 2).

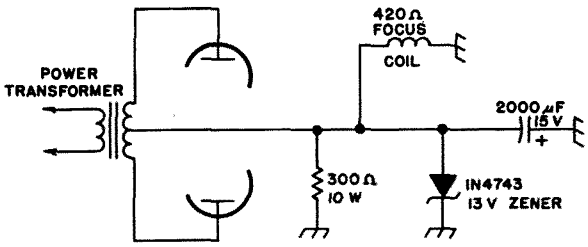

Fig. 3. After some experience with the focus coil circuit, a zener regulator was added as shown here.

The focus coil was wired as shown in the original schematic but has since been changed as shown in the schematic of **Fig. 3.** A 1000 ohm potentiometer connected in series with a 470 ohm resistor was wired across the horizontal output deflection coils terminals to provide for control of horizontal sweep width.

A test point was brought out accessable from the top of the chassis from pin #7 of V6b to aid in camera tune up and adjustment.

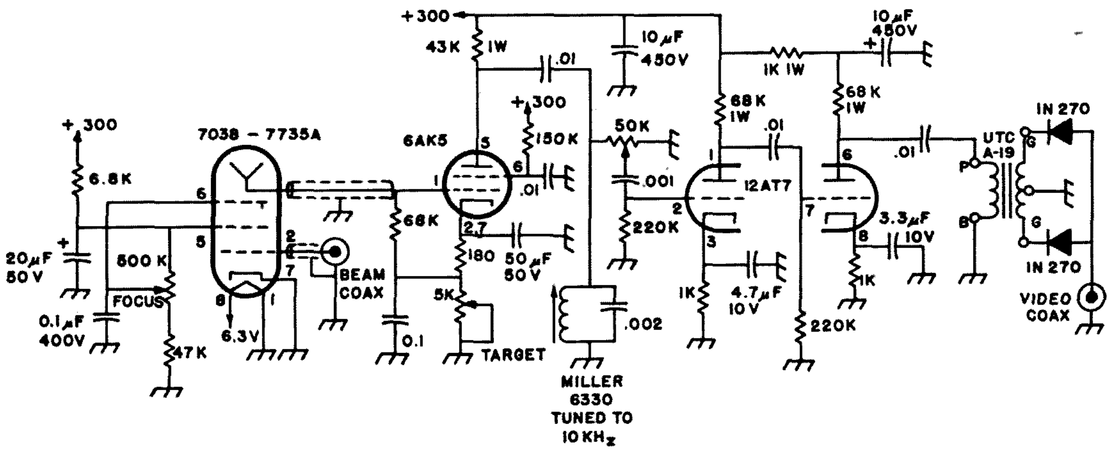

Fig. 4. Complete wiring diagram of the SSTV camera head. Note: pins 9 and 10 blank if shutter deleted on camera using standard vidicon.

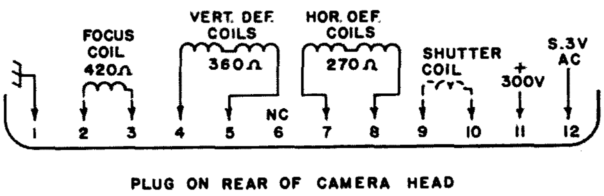
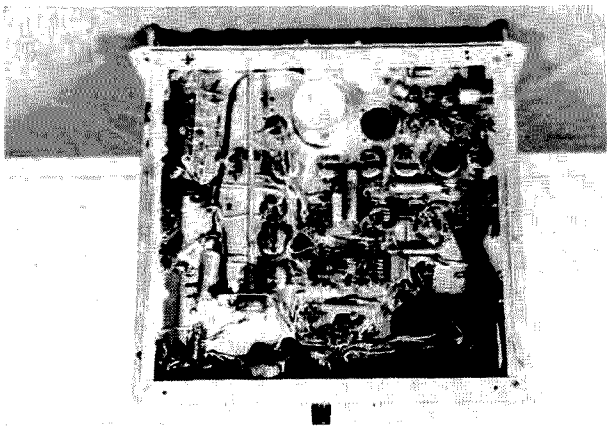
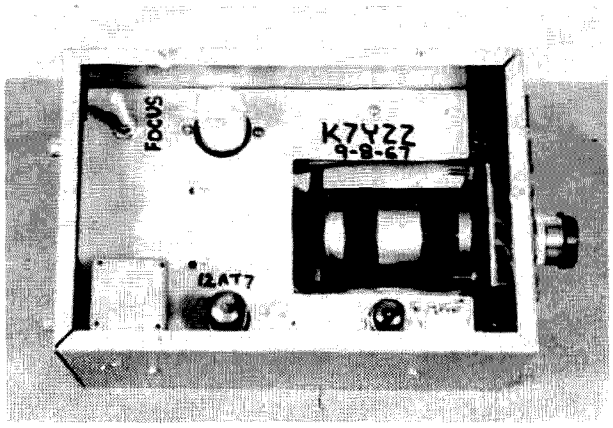
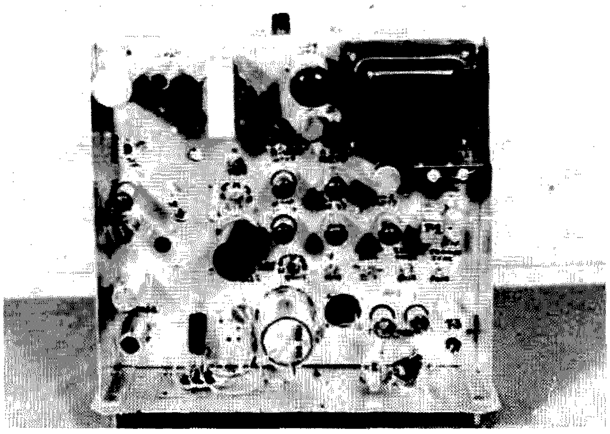




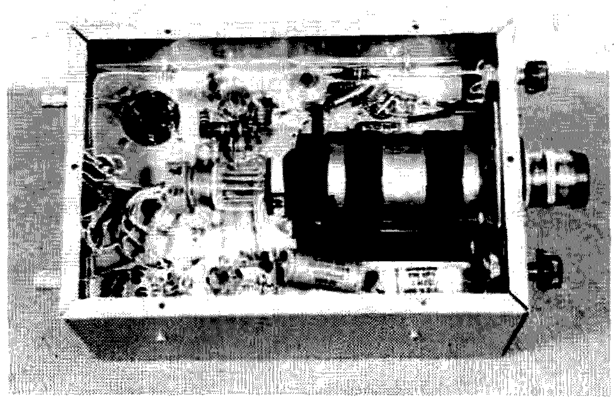
Bottom view camera power and sweep.



Top view of camera head.



Top veiw, camera power and sweep.



Bottom view of camera head.

Adjustment

The detailed adjustment of a SSTV camera is described in the original Macdonald article. Of course those portions referring to the shutter operation do not apply to this camera.

Typical operational voltages on the 7735A SSTV camera head are as follows:

Target: plus 9 to plus 15 volts
Beam: minus 87 volts
Focus: plus 160 volts
#5 pin on 7735A: plus 300 volts
Contrast: mid rotation

The first recognizable picture observed on the camera was reversed. This was corrected by reversing the horizontal deflection connections at the camera head power plug. The deflection yoke also required some minor rotation to level the picture. Optical focusing of the camera is accomplished by changing the position of the Vidicon. With the fixed focus lens referred to earlier in this article I am able to view objects in focus from around 2 feet to 20 feet.

For station identification titles I use a movie titler. This Sears catalog #3 G9350C Magic Master Letters for titling, uses white plastic letters on a black background, and is held approximately three feet from the camera for full coverage.

Live subjects may be scanned, but the individual should remain motionless for about 24 seconds for a good clear picture on the SSTV monitor.

I wish to express my thanks to Copthorne Macdonald, WAØNLQ, for his verbal assistance during the construction of the camera, and to Bob Gervenack, W7FEN, for his cooperation in the on-the-air tests of the camera.

A Cheap and Simple, Tri-Band, Linear Amplifier

Allan H. Matthews WB2PTU
R.D. 1,
Waverly, N.Y.

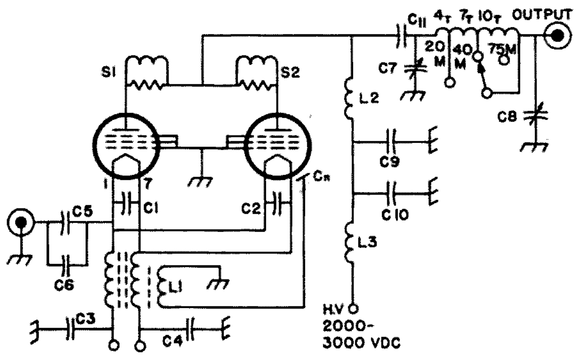

Fig. 1. Schematic diagram of the "Cheap and Simple Tri-band Linear Amplifier."

This article is not for the ham who buys all new commercial gear. He can go out and purchase a nice, new, shiny, chrome-plated linear amplifier for a few hundred bucks and be on the air fast with his 2000 watts PEP. If you are the type of ham, however, who believes in a little elbow grease and ham ingenuity, read on friend, and save some money. 80, 40, and 20 meters are covered because these are the bands most transceivers cover.

I had recently traded all of my gear and purchased the SB 34. This left me with no money for ham gear but with a desire for a higher power, at least for 75 meters. I decided that the linear amplifier must have the following specifications:

1. No screen voltage supply.
2. No bias voltage supply.
3. 500 to 1000 watts dc input.
4. Low cost.

My choice of tubes was a pair of 813's. These are available as surplus from many sources and many amateurs have a few kicking around. Some commercial stations use them for drivers and the ART-13 also used one, so look around. The tube socket is cheap and no fancy blower is needed. Since the SB 34 would deliver 135 watts PEP I decided on the grounded grid circuit. I realize that some commercial amplifiers use 813's in grounded-grid with a bias voltage, but, believe me, they work very well with all grids tied together and strapped to ground. This also saves a few capacitors and a bias supply. The schematic pretty much explains things, but don't be afraid of substitutions. The filament transformer can be a rewound television power transformer. 10 volts at 10 amperes is what is needed if you wind your own. Don't forget the center-tap.

The filament choke is used to block rf from getting into the filament transformer and to ground. You can purchase one for about $18 or wind your own for about 25c. I wound my own. The core is ferrite from the core of a burned out television fly-back transformer. Grind the U shaped piece until you have a straight bar of the material, then give it a coat of Scotch #33 tape to smooth it off. Next, wind one layer, 12 turns, of #12 wire, the wire arranged to be two windings wound simultaneously. To do this fold the wire in the center, clamp it into a vise, stretch it and then wind the choke using both strands, side by side. It requires about ten feet of wire. Use Formvar insulated wire if you can get it. Motor rewinding shops have it on hand. After you have wound the core full, give it another layer of tape. Then wind a single strand of anything from # 16 to # 26 in the same direction directly over the tape, using the same number of turns as you used on the first winding. This will be used for neutralizing. Cover this winding with plastic tape also.

The next expensive item is the kilowatt tank coil. I wound my own, using 15 ft of ⅛ in. copper tubing. My coil is 2¾ inches inside diameter because that's the size can I had on hand. Some pieces of plastic and some plastic cement were used to space the

S1, S2	5 *turns* #16 *on* 47 *ohm* 2 *W resistor.*

windings at about 1⁄16 inches apart. The coil I wound has 21 turns, but 18 would be plenty, as I tried a second tap for 75 meters but it didn't make any difference. Total cost for the coil was under two dollars. The L/C ratio is probably not exactly right but with 1000 watts of dc input, who cares if we lose a watt or two. Besides that, the coil runs cool. So much for the purists.

The amplifier was built for 75 meters but a rugged rf switch from an old tuning unit was in the junkbox and since the SB 34 covered four bands, I decided to make the unit bandswitching. I used a grid dipper to find taps on the coil so the linear would operate on 75, 40, and 20. Taps are as follows:

40 meters . . . 11 turns from the plate end of the coil
20 meters . . . 4 turns from the plate end of the coil

The power supply is conventional and since mine is rack mounted, the power supply control panel contains the 0-500 mA meter and the 3.5 kV plate voltage meter. That way, if I build another linear, I save the price of two meters. I use a variac in the plate transformer primary, but light bulbs in series will work as well to get tune up voltages.

Earlier I mentioned substitutions and here are a couple you will probably make. The plate tuning capacitor is a 240 pF Cardwell but a 150 pF would do the trick. The loading capacitor is another ancient Cardwell (I think it is 1000 pF but I'm not sure) and you might do better with a three gang broadcast variable. This would be about 1100 pF.

Tune up procedure is to warm up the tubes and apply about 1000 volts to the 813's. Tune the exciter and the linear for maximum output. This will be about 300 mA of plate current at 1000 volts. Then take out the carrier and raise the voltage to whatever is available. Operate the linear at 2800 volts at 320 mA for an input of 900 watts dc. Adding the driving power of 90 watts dc of the SB 34 we wind up with very close to the legal limit. Idling current of the two tubes runs about 60 mA.

Neutralization is not critical and perhaps not necessary. C_N is an antenna connector from an Arc-5 but a piece of stiff wire would work as well. There is no need for adjustment.

In closing, let me say that I scrounged most of the parts for this linear amplifier, and what I didn't scrounge, I built. So can you. I have much less than $20.00 in the amplifier itself. The signal reports are gratifying (about 10-12 dB above the barefoot exciter) and this unit can be heard nightly at 3955 kHz where I will be in QSO with K3ABC . . . Break in and join us.

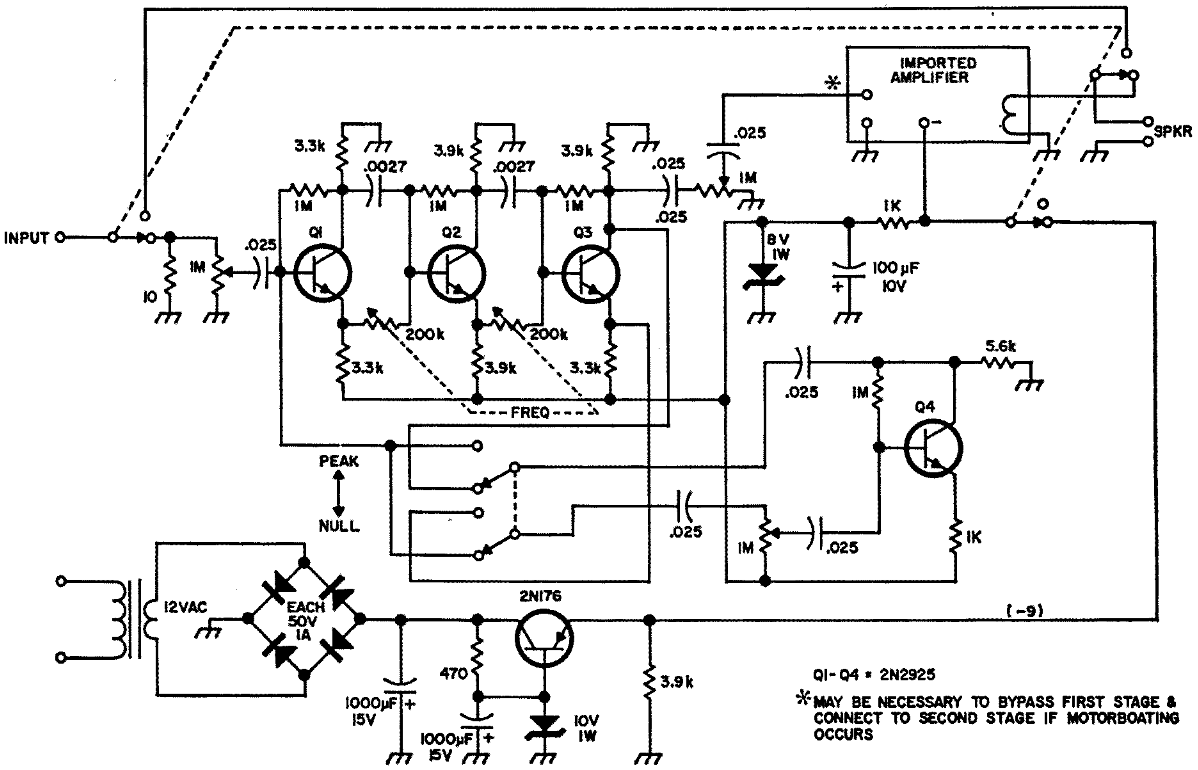
The Beatnote Basher

Roger Melen WB6JXU
Rt. 2, Box 486-M
Chico, Calif. 95926

A Selective Audio Filter

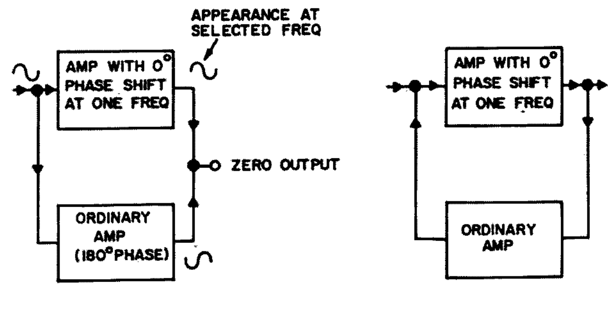


Today's crowded amateur bands require selective receivers. Heterodynes, ignition noise and other interference can wreck a good QSO. Unfortunately, some modern SSB transceivers don't have a notich filter, and aren't selective enough for good CW reception. The "Beatnote Basher" is not a cure-all, but it does offer, in the "reject", mode an audio notch that will knock an undesired heteroydne almost out of the picture. In the accept mode, it proves an extremely sharp passband allowing you to pull a single station out of a pile-up. Also, the installation requires no modification of your present equipment. It is simply installed in the speaker lead of your present receiver, or transceiver. It works with all *if*s, and receivers and tranceivers.

Basically, the idea is not new. The "selectojet"[1] and others are based on the same principal. An audio amplifier is constructed so as to have a phase shift of zero degrees at just one frequency. Q_1, Q_2, and Q_3 comprise such an amplifier. An ordinary amplifier, Q_4, is the placed in parallel with before-mentioned amplifier when the "accept-reject" switch is placed in the reject mode. The ordinary amplifier, which has a phase shift through it of 180 degrees, will have an output which is identical to the phase shifting amplifier except for a phase difference of 180 degrees at the frequency which is to be rejected. If the selectivity control is adjusted so that the gain of both amplifiers is identical at the frequency which is to be rejected, the two signals will add out, while allowing all others to pass through.

In the reject mode, the "Beatnote Basher" acts as an amplifier with feedback, but the feedback is at the optimum phase at just one frequency. The system has greater gain at this frequency than at all others, so that only the desired frequency is heard at the speaker.

Most circuits of this sort utilize a tube type amplifier. Warm-up time, heat dissipation and size were the main factors which



ACCEPT MODE REJECT MODE

discouraged the use of tubes in the author's circuit. The transistor which should be used is rather important. Impedance matching, gain and other consideration point to a high beta transistor. The General Electric 2N2925 has a typical beta of 215 which is excellent for our purpose, and they're only 60c each.[2] Bargain transistors of dubious type are not recommended. The audio amplifier may be any of the 1 watt or 3 watt imported jobs which are presently on the market.[3] The author attempted to homebrew an amplifier, but turned to an imported model when interstage and output transformers were found to be going for the same price as the complete imported amplifier. Any suitable power supply can be used, as long as it is capable of being hum free at currents up to a half an amp or so, depending on the power output of the imported amplifier obtained. Without the amplifier, the current consumption is about 4 milliamperes.

Construction technique varies with the builder, and nothing is extremely critical, although good wiring technique is always advisable. The unit in use here is constructed on a vectorboard with flea clips. Sockets are recommended for the transistors. Presently, the power supply and filter are in separate mini-boxes, but plans are being made to fit the whole thing in one 7" x 5" x 3" mini-box. The front panel controls are: power, in-out, reject-accept, frequency and selectivity. The two gain controls may be put on the back panel, or once the desired values are found replaced by fixed resistors. The filter should be in a shielded box in order to void picking up *rf*.

Once the unit is biult, the input should be connected to the speaker jack and the output to a speaker. With the selectivity control set for maximum gain and both gain controls set for maximum gain and the "accept-reject" switch put in the accept mode, the unit should oscillate quite loudly (tuning the frequency may be needed) and it is not recommended that this be done when others are sleeping). Backing down on the selectivity control should stop the oscillation.

The gain control for the imported amplifier should be adjusted so that the amplifier is not distorting badly. With audio fed into the filter, the selectivity control backed all the way down, the gain control on the input of the filter should be backed down below where distortion occurs. If output is lacking, gain control on the imported amplifier may be adjusted for more gain. For most shacks a 1 watt amplifier is sufficient, but the 3 watt model may be preferred. When finished, the gain controls should be set so that when the filter is put in it has no gain or loss when the selectivity is all the way down and it is in the accept position.

With the filter "in" a signal may be notched out by putting accept-reject switch on "reject" and tuning the frequency until the heteroydne is nulled. The selectivity control should be set about half or two-thirds of maximum for this operation. Once the null is achieved, the selectivity control should be tuned for maximum null.

A signal may be peaked by putting the accept-reject switch on accept and advancing the selectivity control to the threshold of oscillation. The frequency control is turned to peak the desired frequency. The selectivity may have to be readjusted some while turning the frequency control. The operation of the unit is very similar to a Q multiplier except that it operates at audio frequencies in the speaker lead.

The unit may be built into a receiver and then the imported audio amplifier could be omitted, and the output of the filter hooked to the input of the receivers audio.

If properly wired the unit should give no difficulty and serve as a useful receiving accessory. It can also be useful as an audio oscillator when the selectivity control is advanced in the "accept" position. Oscillator output can be taken at the input to the imported amplifier. . . . WB6JXU

The Unijunction Transistor

Roger L. Harrison VK3ZRY
1 Mary St.
North Balwyn 3104
Victoria, Australia

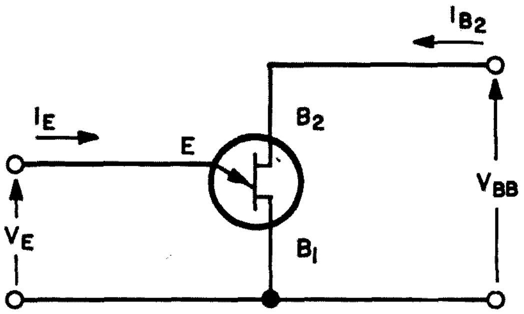

Fig. 1. The symbol and conventions for current flow in the Unijunction transistor.

Perhaps you have seen this rather unusual name in technical journals. Perhaps you have seen an odd-looking symbol (see **Fig. 1**) in a circuit in those very same technical journals. Perhaps you have wondered what this little device does—with its symbol that vaguely resembles that of a conventional transistor but actually behaves much differently. The thing looks (and behaves) like some weird paradox—it has an emitter in the wrong place and *two* (yes two) bases —which incidentally gives us its other name —"The Double-Base Diode," which tends to confuse matters even further.

Well, what is this little device and what can you do with it? Read on, and all shall become clear (or more confused).

The unijunction transistor (hereinafter referred to as UJT) is a semiconductor device possessing quite unusual electrical characteristics. Its construction and operation is markedly different from the conventional two-junction transistor.

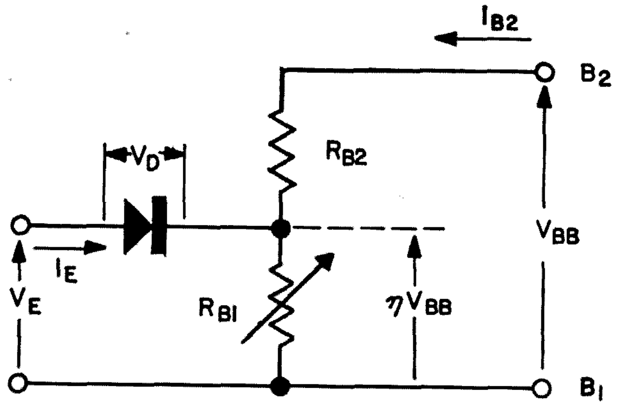

Fig. 2. A simplified equivalent circuit where R_{B2} plus R_{B1} represents the resistance between B_2 and B_1.

Characteristics

Fig. 1 shows it's symbol and the conventions for current flow in the device. **Fig. 2** gives a simplified equivalent circuit. Now, referring to **Fig. 2**, R_{B2} plus R_{B1} represents the resistance between B_2 and B_1. This is known as the interbase resistance, R_{BB}, and is generally in the range 4K and 12K ohms. This is the resistance of a bar of N-type silicon with two contacts at either end. Now another contact of P-type material is placed somewhere between B_2 and B_1 on the N-type silicon bar and this forms a rectifying or diode contact called the emitter (E).

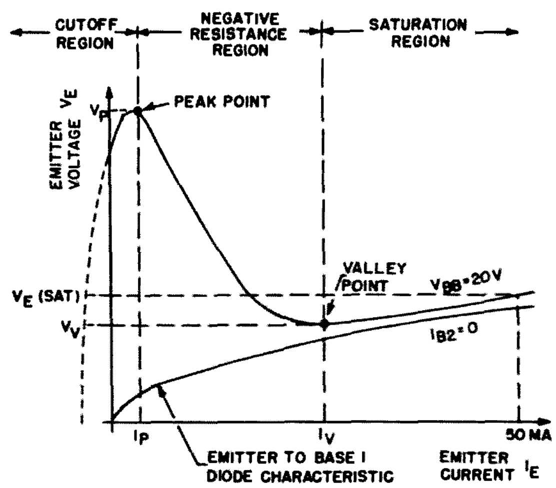

Fig. 3. Plotting the interbase characteristics.

Intrinsic standoff ratio

If a variable potential is connected between B_2 and B_1, with the positive on B_2 and the negative on B_1 (E not connected to anything) the device acts just like a voltage divider and a certain fraction, will appear at the emitter (E). This fraction (η) is called "the intrinsic standoff ratio". The ratio is approximately 0.5 to 0.8 for all types of UJT's. Mathematically the following equation will accurately define η.

$$\eta = \frac{R_{B1}}{R_{B1} + R_{B2}}$$

Peak point emitter voltage

If the emitter Voltage, V_E, is less than V_{BB}, the emitter diode is reverse biased and only a small leakage current will flow. As V_E is raised towards V_{BB} and just above, emitter current will flow as the emitter diode becomes forward biased. The result is that R_{B1} will suddenly decrease its resistance. Consequently I_E will suddenly increase and V_E will drop.

The point at which R_{B1} suddenly decreases is called the "peak point" and the emitter voltage at this point is called the "peak point emitter voltage" and is labelled V_P.

The diagram in **Fig. 3** illustrates the peak point and V_P a little more clearly. These are the static emitter characteristics and you will note that V_P is dependent on V_{BB} (the interbase voltage.) The lower curve (I_{B2} = 0) is the emitter to B_1 diode curve when B_2 is disconnected. These curves can be plotted for any UJT by breadboarding the circuit in **Fig. 4.** Set V_{BB} to convenient voltage in 5V or 10V steps and for each setting of V_{BB} vary the emitter pot. to find V_P first (sudden increase in I_E) and then vary I_E in suitable steps (about 1 or 2 mA steps), reading V_E at each step. You can then plot the static interbase characteristics like those in **Fig. 3.** Disconnecting B_2 will allow you to plot the curve for $I_{B2} = 0$.

From these curves an approximation to η can be calculated very easily. Simply divide V_P (for a certain value of V_{BB}) by the value of V_{BB} for that curve—

Now V_{BB} = 30 V, lets say V_P = 16 volts. at this point

$$\eta = \frac{V_P}{V_{BB}} = \frac{16}{30} = 0.534$$

To be more accurate at lower values of V_{BB} use the equation—

$$\eta = \frac{V_P - V_D}{V_{BB}}$$

where V_D = emitter diode voltage, $\approx$ 0.6 volts

Peak point current

This is marked as I_P in **Fig. 3.** I_P is the minimum current necessary to trigger the UJT. It can be measured using **Fig. 4** with some changes. Disconnect the meter (VTVM etc.) reading V_E. Replace the meter reading I_E (0-50mA) with a 0 to 50 microammeter. At each setting of V_{BB} slowly increase the emitter potentiometer until the meter jumps suddenly. The point just before the jump in emitter current is the value of I_P.

Valley voltage

This is marked as V_V on **Fig. 3.** It is the emitter voltage at the valley point. V_V increases with increase in V_{BB} you may notice.

Valley current

This is marked as I_V on **Fig. 3.** It is the value of emitter current at the valley point, this also increases with increase in V_{BB}.

Static interbase characteristics

These characteristics are a series of curves that relate V_{BB} and I_{B2}. They can be plotted by breadboarding the circuit in **Fig. 5.** With the emitter disconnected at first, a reading of I_{B2} for every step in V_{BB} is taken. The steps in V_{BB} should be at 5V intervals. Then, connecting the emitter, increase the emitter pot. until the UJT fires and set I_E at

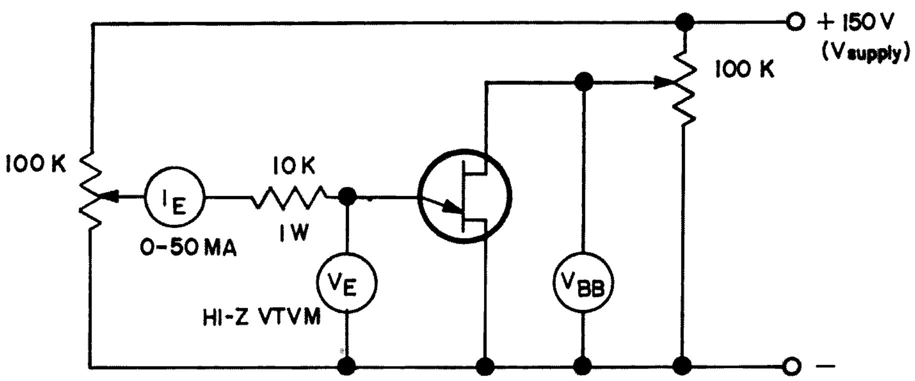

Fig. 4. The minimum current necessary to trigger the UJT can be measured. Keep V_{BB} constant at each step for variations.

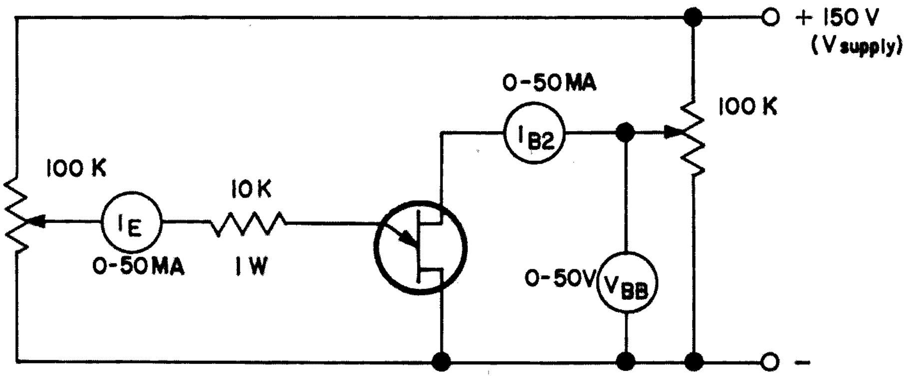

Fig. 5. Static interbase characteristics can be plotted by breadboarding this circuit.

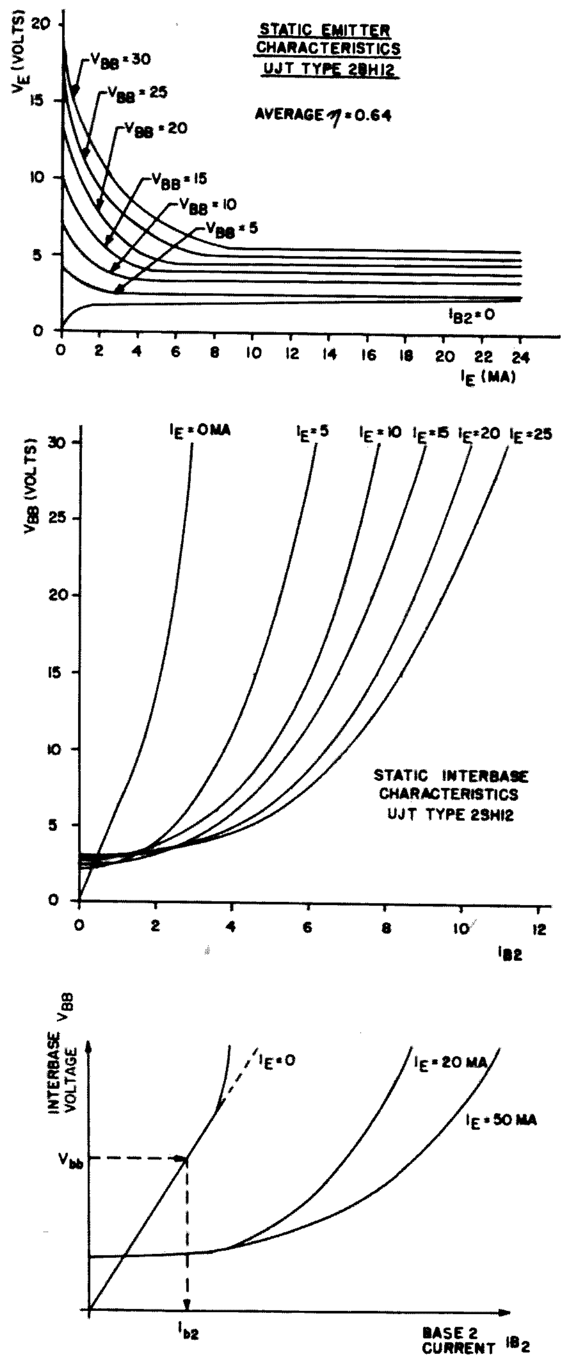

Fig. 6. Resultant curves from plotting by Fig. 5.

5 mA or 10 mA and keeping this constant, take readings of I_{B2} at every step in V_{BB}. Take another set of readings for I_E at say 10 or 15 mA. Continue this for steps of I_E at 5 or 10 mA intervals stopping at I_E = 50 mA. Plotting the results will give a set of curves like those in **Fig. 6.**

A set of curves was plotted, using the above methods, for a type 2SH12 UJT.

Construction

The UJT is constructed in two basic forms known as the bar and cube structures. Most UJT types are of the bar construction form.

The bar construction is shown in **Fig. 7.** A small bar of silicon has two ohmic contacts (not junctions) implanted at opposite ends of the bar. A junction (the emitter)

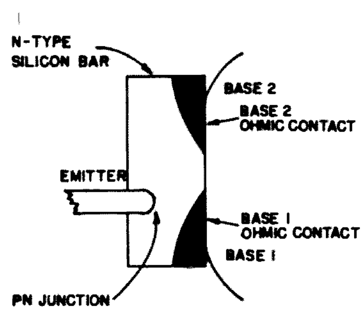

Fig. 7. Bar construction of most UJT types.

is implanted on the opposite side of the bar between B_1 and B_2. This junction is somewhat closer to B_1 than it is to B_2. The unit is generally mounted on a ceramic disc inside a TO — 5 or TO — 18 case and all leads are electrically isolated from the case.

The cube construction is shown in **Fig. 8.** The cube of N — type silicon is mounted on its base-two contact and the base-one contact is a thin wire alloyed into the top of the cube. The emitter is alloyed into the

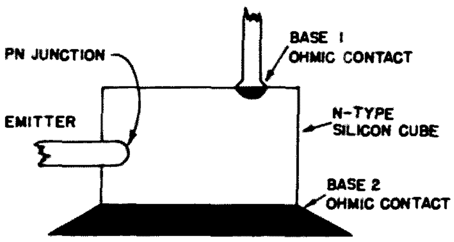

Fig. 8. Cube construction. This type is usually mounted in a TO—18 package.

side of the cube and a PN junction formed. This type of construction is usually mounted in a TO – 18 package.

This type of construction gives different characteristics to the bar type. Owing to the small contact area and shape of B_1 a higher intrinsic standoff ratio (n) can be achieved with much smaller spacing between E and B_1. This produces a lower I_P, short turn-on time, lower valley voltage, and permits operation at reduced voltages. Unfortunately cost is generally higher. **Fig. 9(a)** and **9(b)** illustrates the different static emitter characteristics of typical bar and cube structure UJT's.

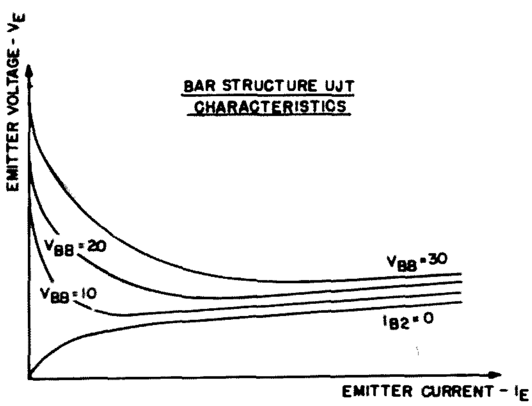

Fig. 9A. Characteristics of a bar type UJT.

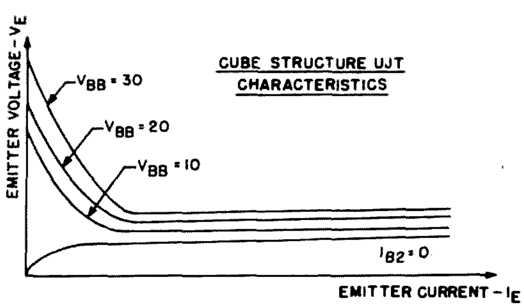

Fig. 9B. Chracteristics of a cube structure UJT.

UJT circuits

Seeing as most types of available UJT's are of the bar construction type I will only consider these in the following discussion.

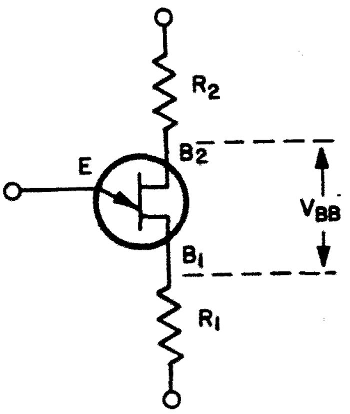

Fig. 10. Resistor R_2 compensates for temperature variations.

Bias circuits

The various parameters and characteristics of a UJT are subject to temperature variation; some more so than others. Now V_P will vary with temperature and is principally due to variation in V_D (see **Fig. 2**). This effect is usually compensated for by a resistor, R_2, in **Fig. 10.** As the temperature increases so will R_{BB}; V_{BB} will increase owing to the voltage divider action of R_2, R_{BB} and R_1.

The resistor R_2 can be chosen from the following equation

$$R_2 = \frac{R_{BBO}}{2\ V_1} \quad (\text{for } R_{BBO} \text{ see } \textbf{Fig. 6})$$

this equation is only approximate and some juggling of R_2 might improve the compensation, but generally it will be close enough for a wide range of UJT's. Also, for the circuit in **Fig. 10** V_P is given by: $-V_P = V_1$.

The resistor R_1 should generally be kept below 100 ohms as it controls the Valley Voltage (V_V) and Valley current (I_V) (see **Fig. 3**). Use what you have on hand.

Relaxation oscillators

The relaxation oscillator shown in **Fig. 11** can be used for many applications. For example; tone oscillator, timing circuit, pulse generator, sawtooth generator or a trigger circuit.

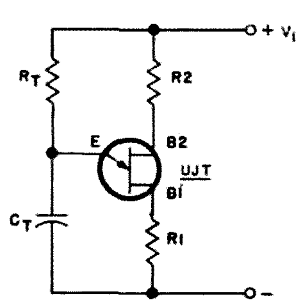

Fig. 11. The relaxation oscillator may be used for many purposes.

When V_1 is applied C_T appears as a short circuit and thus E is reverse biased and does not conduct. As C_T charges through R_T the emitter voltage rises exponentially towards V_1. When the voltage reaches V_P the emitter suddenly conducts and C_T discharges through E and B_1 via R_1.

The emitter then ceases conducting and the whole process begins again. The waveform produced is shown in **Fig. 12.**

The approximate frequency of oscillation is given by:

$$\frac{1}{R_T\ C_T\ I_n \dfrac{(\ 1\ )}{(1 - \eta)}} \text{ Hz}$$

the equation holds providing R_1 and R_2 are small ie. $R_1 \leqslant 100$ and R_2 from previous equation but less than 1000 ohms.

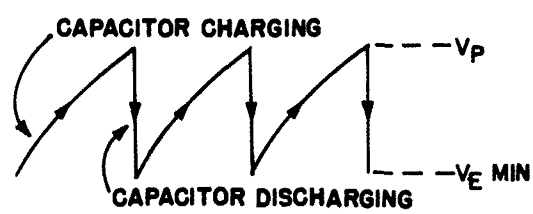

Fig. 12. Waveform produced from the relaxation oscillator.

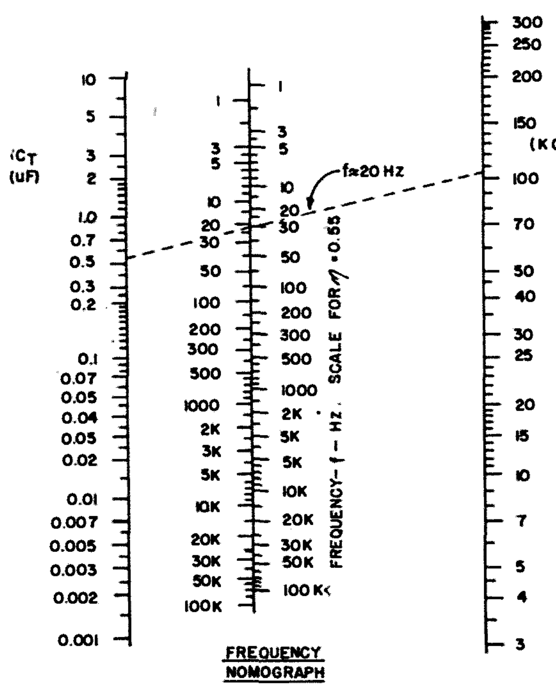

Fig. 13. Nomograph to assist in the design of a relaxation oscillator.

To save calculation in many instances a nomograph (**Fig. 13**) will assist in the design of a relaxation oscillator using a UJT.

Two frequency scales have been given. One for a value of $\eta = 0.55$ and another for a value of $\eta = 0.65$. Use the scale appropriate to the value of η for the UJT you are going to use. An example for a practical circuit is given later. (see **Fig. 16.**)

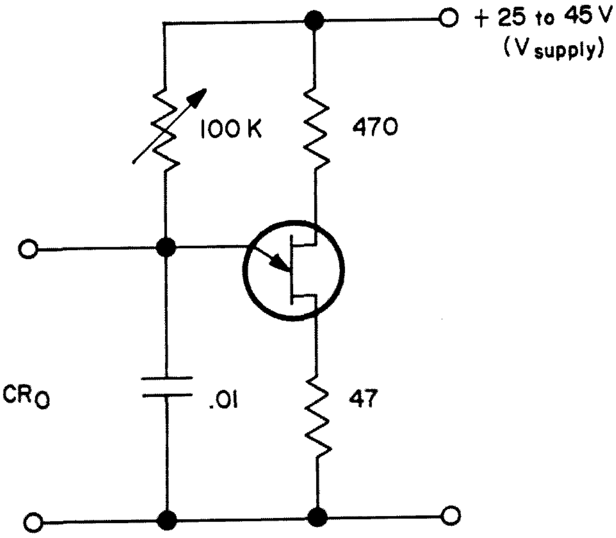

Fig. 14A. A practical circuit built and tested by the author.

A wide range relaxation oscillator

The circuit in **Fig. 14(a)** shows a practical circuit built and tested by the author. I used a Japanese UJT, the NEC-2SH12. It performed very well, the frequency range being 500 to 1. I inspected the waveforms with a Hewlitt-Packard CRO and the results are shown in **Fig. 14(b)** and **14(c)**. The circuit would not oscillate below 1kHz as the timing resistance R_T was too great to allow the emitter to "fire". The frequency is easily lowered by increasing C_T.

This circuit has great potential for the sweep generator in a CRO, rf sweep generator or Panaramascope. Unfortunately the output has a non-linear rise as can be seen in **Fig. 14(b)** and **(c)**. This can be overcome in two ways. **Fig. 15(a)** shows R_T returned to a higher voltage supply. This is OK and gives reasonable linearity providing a higher voltage supply is available. It suffers from a disadvantage though—the frequency is not as stable as it would be with a single supply.

In **Fig. 15(b)** a transistor, connected in a common-base circuit, uses the high output impedance of the circuit to maintain a relatively constant charging current for the timing capacitor C_T.

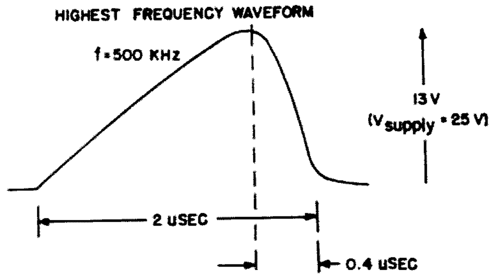

Fig. 14B. Highest frequency waveform.

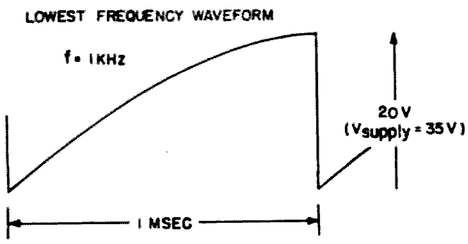

Fig. 14C. Lowest frequency waveform.

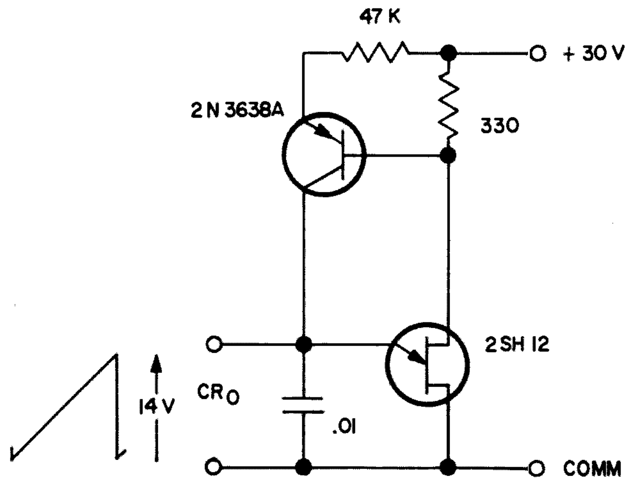

Fig. 15B. Using high output impedance to maintain a relatively constant charging current.

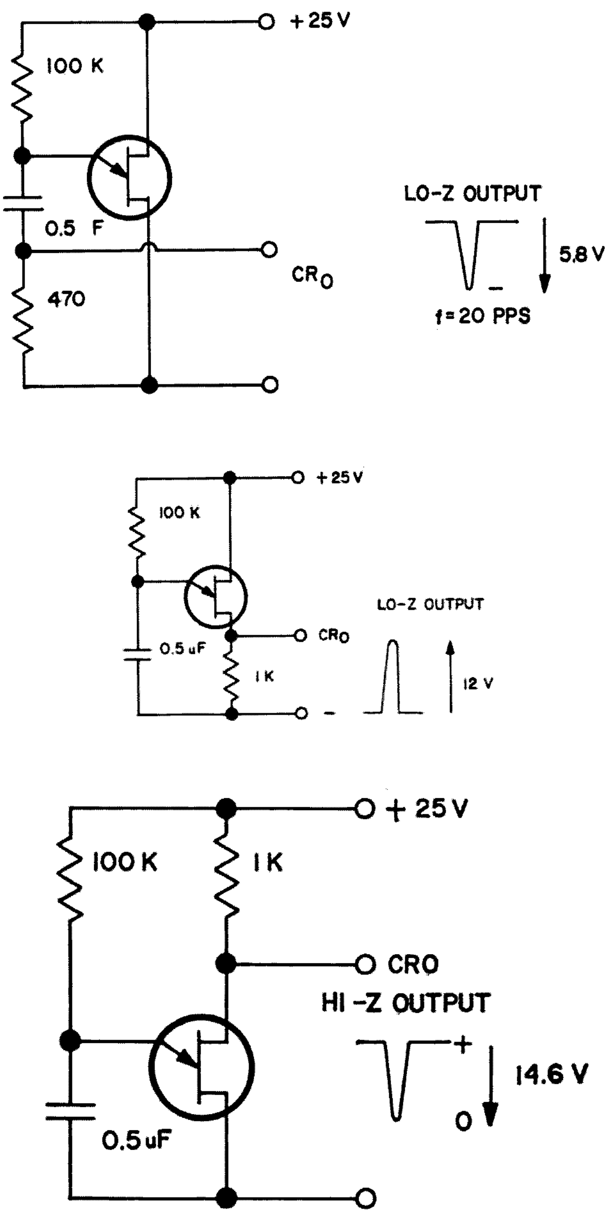

Fig. 16A., B., and C. Several circuit configurations.

Pulse generators

A current pulse will flow in the emitter, base-one, and base-two circuits each time the UJT "fires" in a relaxation oscillator. Thus, a relaxation oscillator can be used as a very efficient pulse generator giving either positive or negative output pulses at various impedance levels. Several circuit configurations are shown in **Fig. 16(a) (b)** and **(c)**.

The output pulse from these circuits has a relatively fast rise time and quite a slow fall time compared with the length of the pulse. A significant improvement in this state of affairs can be made by using an inductance in the B_1 circuit. A transistor can be used to invert the output pulse. (See **Fig. 17**).

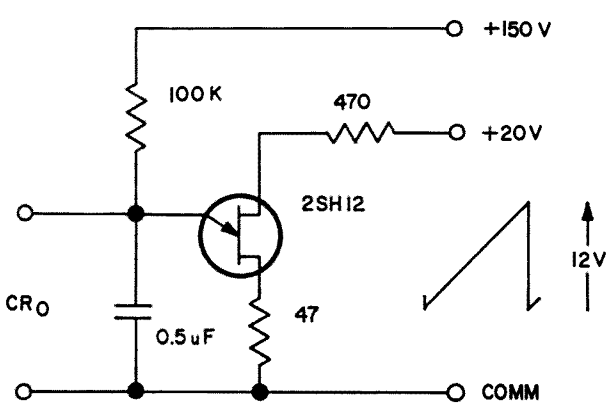

Fig. 15A. R_T returned to a higher voltage to give better linearity.

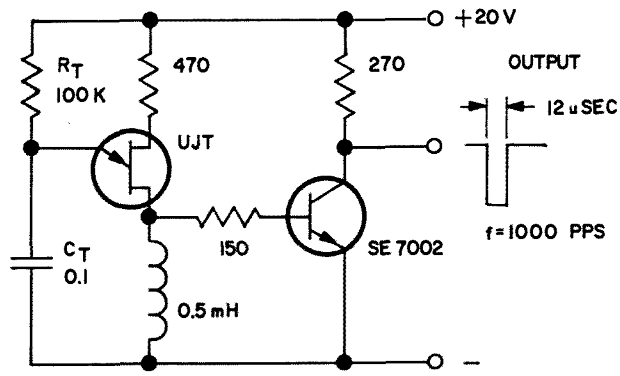

Fig. 17. Inverting the output pulse by use of a transistor.

A pulse generator can be designed by using the nomograph of **Fig. 13** and picking the circuit configuration you desire from **Fig. 16.** The resistor R_1 shown in the circuits (**a**), (**b**) and (**c**) of **Fig. 16** can be chosen by the "um-now-let-me-see-what-have-we-got" method. Juggle its value and the supply voltage to obtain the output voltage you want.

For more critical applications the circuit in **Fig. 17** can be used. The width of the pulse is determined by the inductance in the emitter (L). The frequency of the pulses (or number of pulses per second) is determined by R_T and C_T. The rise and fall times will be quite short, typically 1/20th to 1/50th of the pulse width "t".

UJT timers

A timer can be designed using the relaxation oscillator principle. Referring to **Fig. 18,** when S_1 is closed, C_T charges to the peak point voltage at which time the UJT "fires" and the capacitor C_T discharges through the relay which closes. One set of ((changeover) contacts holds the relay closed. Opening S_1 returns the circuit to its original condition. This circuit is useful for periods up to 15 or 20 seconds.

The best way to design a circuit like this is to haywire it together and juggle R_T and C_T until you achieve the desired result. I found this method reasonably fast and calibrating the pot. is easy. Note that the relay should be physically small so that it has low operating power. A huge 600 or 3000 type relay just won't work (I tried).

Have a look in the **G.E. Transistor Manual** for more timer circuits.

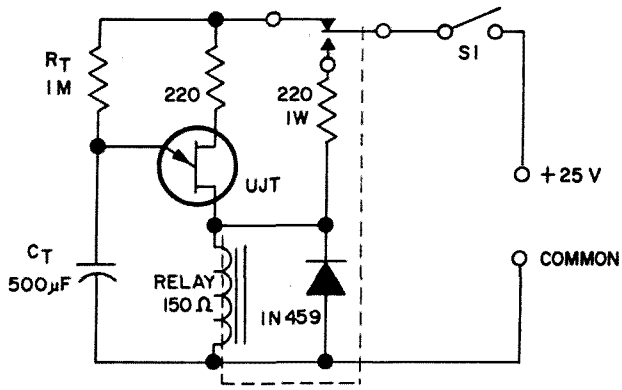

Fig. 18. The relaxation oscillator principle used for a timer circuit.

Sweep generators

Fig. 19 gives the circuit of a very handy little sweep generator. The coils can be switched if you like. It will work from about 60 kHz to about 60 MHz, depending on the transistor used for SCZ. If you don't want to go really high in frequency an OC45N will work admirably.

The circuit is fairly non-critical and some

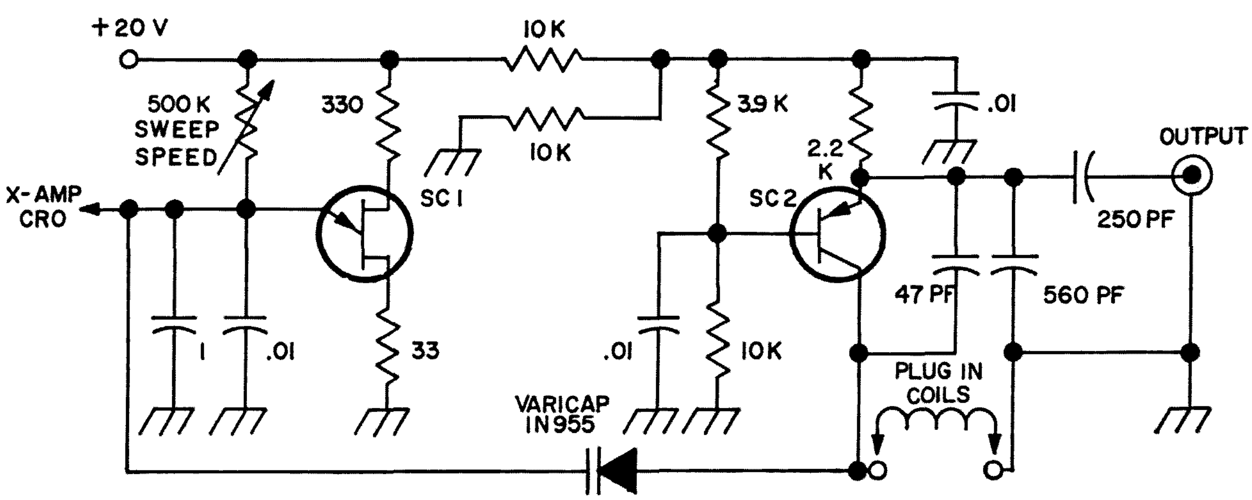

Fig. 19. The circuit of a very handy little sweep generator.

variations are permissable. The supply could be two 9V batteries in series. Coils are found by experiment. For 455 kHz the coil from an *if* transformer (with capacitor removed) is ideal. To limit the sweep range add a capacitor across the coil and retune the slug. The output is quite high and some attenuation may be necessary. Connect a high resistance in series with the output to effect a reduction.

Well, there we are. Knock up a few circuits and find out about UJT's. I think you may find a useful circuit in this article. For more ideas look up the references mentioned below.

CLUB SECRETARIES NOTE

Your club can round up some extra funds by imploring, cajoling, convincing, or forcing your members to subscribe to 73 Magazine. Never mind the cries of anguish, just remember that you are doing what is best for them—and the club.

Subscriptions to 73 are normally $6 per year. The special club rate is exactly the same: $6. The only difference is that the club treasury holds 25% of the loot and sends the rest to 73. Send us $4.50 for each one year subscription, in groups of at least five subs. Just think, if your club has 10,000 members you can quickly get $15,000 for the club on this deal!

Send the subscriptions to us on 3"x5" cards, giving the name, call, address, city, state and zip code of each subscriber. If the subscription is a renewal please include the address label from a recent 73 wrapper. Indicate all renewal subscriptions so we won't start a second sub. We have been known to do that.

Send to: Club Finagle, 73 Mag. PETERBOROUGH, N.H. 03458

What's Out There?

Jim Ashe W1EZT
P.O. Box 343
Peterborough, N.H. 03458

The Universe is out there, and men go into it for short visits. Maybe one day they will live in space and we can sit down here and talk to them at distances of hundred-thousands or ten-millions of miles. Is it possible there are other intelligent beings out there already, who have never seen our sun except as a distant star?

Within recorded history people not very far removed from us believed the world extended a few miles from top to bottom, and maybe as many as several hundred from one edge to the other. They thought this little area was provided for raising people, as we might grow radishes or bugs in small dishes. The sun, moon, and stars were ornaments or maybe a part of the machinery of the Gods, but nothing more.

One Greek philosopher had a ready reply to a question of "Which is most important, the sun or the moon?" "The moon," he said. "The sun shines in the day when it is light anyway."

All through history men with new ideas have had to be careful. You could get killed that way, or at least written off as a useful member of society. Evidently you still can, if news reports are to be accepted. Yet there has been a slow trend to decreased reliance upon dogma in favor of science and technology, which really works. And just a very few years ago some scientists met (quietly) to assess the chances there might be life on other worlds.

Their question was, "Are there intelligent beings on other planets who would be interested in talking with us?" They had all of human knowledge to work with (it doubles every few years now) and while they could not come to a definite yes/no result they could estimate at least 40 and perhaps fifty million planets interested in communication, *right now*. And there could be about ten times as many worlds with intelligent life.

We'll have to make considerable progress in exploring space before we come upon grounds for a more definite opinion, or for one with a narrower margin of error. Perhaps we will discover a surprise: an explorer's camp left on the Moon. And scientists are very puzzled over some points about the two moons of Mars, which act like artificial satellites.

But the strongest chance seems to be that somehow we'll overhear a conversation or intercept a message aimed at somebody else. SWL's in space? Most probably, and radio amateurs too. Ham radio is in a doldrums now, but may be facing a greater opportunity than was open to it in the early 1900's. We'll have to enlarge our perspectives considerably to meet that challenge.

Are there worlds out there?

This is an excellent question because if there are no worlds in space other than ours we hardly need look for people living on them. A world in space without a nearby sun would be too cold to live on, and so if we want to find worlds we start by looking for stars.

What do we see if we look up at the skies late at night from some clear hill? We see a tiny bit of the universe, and several thousands of stars. I have always felt it is a splendid sight, and very thought-provoking. Except for a few wandering lights now known to be planets and some others that are specially interesting to astronomers, these stars are suns. Each one of these suns—just think! Each one *might* have a planet something like our own. If this is a possibility why haven't astronomers increased the magnification of their telescopes so we can see those stars close-up and observe any possible planets?

The uncompromising laws of nature intervene. The stars are too far away, and there is a practical limit to the magnification any optical device can achieve. There is another limit too, set by the erratic jiggly nature of our atmosphere. We cannot look to see if there are planets circling the stars.

Yet if we want to discover life on other worlds, we have to sort out the worthwhile stars from all the stars we might look at.

If we cannot see planets how do we even know they exist? Not so long ago most astronomers felt it was quite likely our own world was something of an accident, and others must be so rare it would not be worthwhile to look for them.

A simple observation finally terminated that line of thought. Our sun does not rotate very fast. Our sun has planets—we live on one of them. Is there any connection between the planets and the sun's slow rotation? Yes, and the modern theory of magnetohydrodynamics explains how the sun could have lost some of its rotation to its planets. Now we know why the planets go in the same direction the sun turns, and about the same axis.

Looking outward we discover some stars that rotate rapidly, and many that do not. Very probably the slow ones are slow because, as our sun did, they gave up that energy of rotation to their planets. Current thinking is that nearly 70% of all stars have planets, and each one may have two or three that might bear life. Our own system has three planets and a moon (ours) that might have life, and Mercury, Jupiter and Saturn are less certain prospects.

Life

Modern research into the question of how life originated is complicated, interesting, and not yet complete. We can be certain there was no life in the universe at its creation about 26 billion years ago. What happened since then to bring life into the scene? What happened here?

Well, the current trend in thinking about this question is that life appeared naturally here about 4 billion years ago. The earth was very different from the earth we know, and a number of chemical processes were going on that we can only observe in sealed experimental chambers now. The chambers have to be sealed because if we left them open bacteria and insects would enter to consume any life-like chemicals we might produce.

It turns out we do produce complex chemicals identical with those of life by simple heating and mixing processes together with electrical discharges and radiation similar to what we think were found on earth about the time life originated. Researchers are convinced this process, going on naturally for a few millions of years, would generate

a molecule that could duplicate itself. The rest of the story of life would be evolution, not creation. Could this process take place elsewhere?

Best results indicate it certainly could, and probably would. And other studies indicate that once life appears it is extremely hard to destroy. Experimenters thinking about life on other worlds have tested some of their ideas by looking for unusual kinds of life on our own world and they have found it in environments so harsh and unusual as to qualify "extraterrestrial, just happens to be here." For example, bacteria live in the cooling water of nuclear piles, an environment once regarded as absolutely lethal. Some insects found in the arctic will cook to death in the palm of a man's hand. Other insects can be dessicated—as dry as old seeds, and will live again when placed in water. Seeds thousands of years old, and some bacteria sealed in salt crystals for millions of years have come to life again in the laboratory. And some plants are known to live naturally in water at 194 degrees F., and others have survived higher tempera-

EXTREME	EARTH (life zone)	MOON	MARS	VENUS	ELSEWHERE
Temperature	—100° F To +212° F	—210° F To +212° F	—210° F To +80° F	? Very Hot	All Extremes or Lack of Them
Pressure	Vacuum To 8 Tons/in²	Vacuum on Surface	1/8 Earth Pressure	?	
Radiation	To Nuclear Pile Intensity	Moderate	Low	Low	
Life?	Yes— Everywhere	Possible Under Surface	Possible on Surface	Maybe in Atmosphere	Almost Certainly

Fig. 1. Temperature and other conditions in some known parts of space are within extremes known to be habitable here on earth.

tures than that. Lab studies have shown bacteria can thrive in jars pumped and cooled to the conditions known to exist on Mars.

Apparently, once life appears it can adapt to gradually harshening conditions fast enough to continue in the face of anything short of a cosmic disaster. If there ever was life on the moon, on Mars, Venus, or elsewhere there probably still is. Few people will be surprised if the first men visiting the moon bring back fossils, or even small plant-like things that live safely a few feet under the moon's surface.

Extraterrestrials

Once life has appeared, intelligent life is likely. The continual generation, survival and destruction of living beings wherever we see life tends to emphasize the development of the ones most able to survive. If there are many different environments there will be many kinds of beings, and the odds favor the development of intelligence sooner or later. And, once it appears, it wins over all the competion almost instantly, on a cosmic time scale. And then by degrees we have science, technology and engineering, and finally interest in other worlds.

Of all the risks involved, the interest in other worlds seems to be the greatest. It seems ten times more likely that intelligent races exist elsewhere in space than that they will be concerned about what is outside their skies. Our own history bears this out.

But if we are interested and they are there and interested too, how will we find them?

Some thinkers suggest they may have found us. I'm not referring to the flying saucer reports, which seem rather faddish to me. Some historians suggest we must have had a real visit at least once in recorded history and maybe we can find a description of it somewhere. Others suggest we already have the records but we don't understand them, and point to various odd legends of supernatural beings or visitors.

If we have had visitors from other star systems we are likely to find traces on the moon. Our moon, handy to the most interesting planet in the Solar System (from our own viewpoint at least) would offer an excellent base for observing a possibly dangerous planet (it's safe to suppose *all* planets are dangerous if they are as ours was hundreds of thousands of years ago) while simultaneously mining nuclear fuels for a re-

YOUR CALL

Please check your address label and make sure that it is correct. In cases where no call letters have been furnished we have had to make one up. If you find that your label has an EE3*&* on it that means we don't know your call and would appreciate having it.

turn trip. If any traces have been left over the past few hundred-thousands of years they are probably still there. The Moon has no weather to obliterate footprints and engineering structures.

Looking a little farther out we come to Mars, interesting in itself, and its two moons. Phobos, the inner moon, behaves like a hollow shell in space and both Deimos and Phobos are in orbits unlike those of any other satellites except our artificial ones. And astronomical records suggest both moons *may* have appeared in space between our years 1862 and 1877. Several other observations about Mars are interesting, and it will probably be visited by humans next after our moon. That expedition may bring back a bundle of news!

But the most probable way we can discover any other people is by their radio communications. We have some idea how many planets might be interested in communicating with us, but what are the odds one is both interested and near enough? How near is near enough? And how will they go about it?

Right here the question becomes one of most fascinating things we can find to think about. Here we are at the sea shore, as we were once before in this same century. We can guess, we can conjecture, and while the experts are working like made on the problem there are thousands of amateurs per expert. The odds for success favor the men with two-hundred and thousand-foot reflectors and yet simply because their gear is so powerful and cumbersome they cannot try all possibilities with it. Only the best. Can ham radio jump off again, as once before, and find a place in the future

A New Material—VELCRO

R. Bailey, K3AQH
326 Hoffnagle St.
Philadelphia, Pa. 19111

In this space age new things are coming along all the time, sometimes at a pace that is hard to keep up with. Some of these new ideas may be of use to hams, and a specially good one is VELCRO.

VELCRO is that stuff used on your family doctor's blood pressure cuff. If your wife does a lot of sewing, she may already know about it, and maybe there is some in her sewing box. It is a rather ordinary looking product, but when you look closely, you see it comes in two types: one with a forest of tiny nylon hooks and the other with a surface resembling felt.

When you press the two pieces together the hooks engage the felt, and if you press the attachment becomes stronger. The force necessary to separate the pieces is that required to bend one hook times the number of hooks. Since there are many hooks and the nylon is "kinda" stiff, the holding power becomes quite useful.

Applications

After thinking about this a number of ideas come to mind. For mobile operation, for instance, you can cement a piece of VELCRO to the mike and a mating piece to the dash; now the "right" spot is a general area rather than a precise mechanical point. No fumbling in traffic.

You can make up a strap of VELCRO to go around your mobile log, with some elastic or a rubber band to complete the loop. After opening your log to the correct page you slip this loop over it; the mating piece of VELCRO is located on the appropriate shelf or surface. When you put the log down there, it won't slide. Put another piece of VELCRO around the pencil and it won't dance around either!

If there is a fairly wide base area in your car, you can use some VELCRO to hold your rig in place. Three or four strips on the bottom of the rig (use low-profile bolts, rivets, or cement) against mating strips on the mounting surface will provide a surprisingly strong mounting arrangement. In the same way you can hold your rig, or parts of it, very nicely in place if you are thinking of a tilted shelf to improve panel visibility.

VELCRO will hold small, light chassis in place on top of larger, heavy ones, too. This idea has very good possibilities in view of the trend to smaller, lighter electronic components. Use noncritical pieces of VELCRO in place of harder-to-assemble (and more expensive) mechanical mounting assemblies.

When you put up your mast, wrap a piece or two of VELCRO near the top. When you are up there with test gear it can serve as a third hand holding your field strength meter or whatever.

If you are experimenting with VHF yagis, lay out a strip of VELCRO along the boom. Wrap a mating piece around the center of each element, and when you press the element down onto the boom it will stay put yet is easily moved.

Other suggestions are a bulletin board with some VELCRO for semi-permanent mounting of clip boards, pens, charts, even a small card file. Some tools might be hung on VELCRO, too, in the workshop.

$1,000,000 TVI SUIT FILED

Grid, W4GJO, the well-known VHF pioneer, is being sued for $1,000,000 for causing TVI. His case, if lost, could mean the end to amateur radio. Please read this incredible case.

It is the purpose of this letter to set forth in as factual a manner as possible the events which have taken place in the subject TVI case.

This case was first brought to the attention of the Sarasota Amateur Radio Association in April 1968 when Mr. Ansel Gridley W4GJO requested the assistance of the TVI Committee. Mr. Gridley, who resides at 2439 Goldenrod Street, Sarasota, had received a TVI complaint from Mr. Lee H. Eggers, whose address is 2451 Goldenrod Street, next door to Mr. Gridley. Mr. Gridley explained that his neighbor had complained of interference on his TV set on two other occasions during the last ten years and each time the interference had been eliminated by the addition of high-pass filters at the TV sets. This time, however, Mr. Eggers had refused to consider the installation of a filter or to cooperate in any way. At that time Mr. Gridley wrote to Mr. Eggers to the effect that he would be happy to investigate the cause of the interference at Mr. Eggers' convenience. A copy of this letter was filed at the FCC office in Miami. As a result of Mr. Gridley's request, Mr. Larry Loper, W4WHF, of the TVI Committee contacted Mr. Eggers, who again declined to discuss the situation.

On August 1, 1968, an advertisement appeared in the Sarasota Herald Tribune. This ad was placed in the newspaper by Dixie Lee's Bar and Package Store and contained an "editorial" ostensibly written by the proprietor, Lee Eggers. The object of the editorial, of course, was Mr. Gridley.

As a matter of interest, Mr. Gridley is the owner of Tel-Appliance, Inc., one of the larger TV and stereo sales and service stores in Sarasota. As part of this operation, Mr. Gridley also handles the most complete line of amateur radio equipment and supplies on the west coast of Florida. Mr. Gridley, known as "Grid", has been a licensed amateur for over 30 years and is well known in VHF circles throughout the country.

I personally met with Mr. Eggers at his place of business on August 3 to discuss his complaint. He said that he had experienced interference in varying degrees with various TV sets and other appliances during the past 10 years. He said the interference to his new color set was unacceptable and that he would seek to prevent Mr. Gridley from operating. The possibility of a lawsuit was mentioned. Reluctantly, he consented to allow the TVI Committee to investigate the nature of the interference in his home.

On the evening of August 8, Mr. William Quigley, also of the TVI Committee, Mr. Harry Hartnup, owner of Harry's TV from whom the TV set was purchased, and myself were admitted to Mr. Eggers' home. By telephone, Mr. Gridley was asked to begin transmitting. The 28.5 MHz. band was used for the test since this has been the band most frequently used in recent months. Severe interference to both picture and sound was apparent on all channels including UHF channel 38. Several orientateons of the transmitting antenna were tried as well as power levels of 100 and 1000 watts average. The degree of interference remained substantially the same throughout the test. Single-sideband transmission was employed in all cases. It was determined that an antenna mounted pre=amplifier was being used by the TV set. When this device was disabled by disconnecting its power supply, the degree of interference was reduced significantly. This concluded the initial test at Mr. Eggers' home.

The TVI Committee also inspected the amateur station of Mr. Gridley. The transmitter in use is the Drake Model T4X followed by the Drake L-4 Linear Amplifier. A Drake Model TV-1000LP low-pass filter and a Johnson Match Box antenna coupler are used at all times. The antenna used on the 28.5 MHz. band is connected to an earth ground. To all appearances, the station is installed, maintained and operated within the norms of good engineering practice. Mr. Gridley also has several TV sets in his home. These sets are fed from an outside TV antenna and through a high-pass filter and a distribution amplifier. It was witnessed by the committee that no trace of interference occurred on these sets under any conditions of operation of the amateur station.

It was the committee's opinion at this time that the interference was principally due to

overloading of the single-transistor pre-amplifier which is loćated at the TV antenna and in a high intensity RF field. This overloading and consequent crossmodulation is producing spurious signals throughout the entire television spectrum. Under these conditions, rejection of the interfering signals within the TV set is not possible. The installation of a high-pass filter ahead of the pre-amplifier was considered but disregarded due to the weather-proofing problem. It was the recommendation of the committee, therefore, that the offending pre-amplifier, a Bonder-Tongue U-V Amp-2, be removed entirely. It was recommended that a Jerrold Model TA-66 amplifier be installed at the TV set and that a high-pass filter be installed at the amplifier input. The TA-66 is generally intended to be used as a four set coupler. It does, however, have approximately the same gain as the Blonder-Tongue amplifier, and some amount of input tuning is provided. The TA-66 operates on VHF channels only.

Mr. Eggers, his attorney, Mr. Jack Windt, and Mr. Hartnup were informed of the results of the committee's investigation and the above changes were proposed. It was also stated that the new amplifier and high-pass filter would be supplied at no expense to Mr. Eggers. The possibility of subscribing to the cable TV service which is available in the neighborhood was also discussed. It was stated that this service had been tried but that the results were unsatisfactory for reasons not related to this problem.

During the first week of September, the recommended changes were accomplished by Mr. Hartnup. Shortly thereafter, Mr. Hartnup and myself repeated the original tests at the Eggers' home. With Mr. Gridley transmitting under the same conditions as previously, there was no trace of video interference except on channel 3. Channel 3 exhibited a very slight variation in intensity on peaks of modulation. Audio interference was present on all channels, however, and to a degree approximately equal to that of our first visit. This interference was recognized as being due to audio rectification or detection in the audio amplifier stages of the TV set. The elimination of this type of interference is generally difficult and dependent upon trial and error methods. The first step would be to bypass or shield any long leads associated with the audio stages. It was proposed to Mr. Eggers that the TV set be removed to Mr. Hartnup's TV store and that the necessary work be performed. This proposal was refused. Mr. Eggers also stated that he was not satisfied with the quality of the reception with the new amplifier and that he wanted it removed and his original pre-amplifier re-installed.

It should be mentioned that Mr. Eggers is an avid television viewer and expects to receive signals reliably from stations other than the principal stations in the area. These principal stations are WTVT-TV, channel 13, and WFLA-TV, channel 8, both in the Tampa-St. Petersburg area, a distance of about 50 miles over flat terrain. The other stations which he expects to receive include several lower power stations in the Tampa-St. Petersburg area, one in Ft. Myers, a distance of 65 miles, and one in Orlando, over 100 miles away. Even in the case of the principal stations, Sarasota is considered to be a fringe area.

Also during the month of September, Mr. Hartnup contacted the RCA factory in an effort to obtain their assistance on this problem. Their suggestions were essentially the same as those of the TVI Committee. As a matter of interest, the set uses the RCA CTC 30 color chassis.

During the latter part of September, Mr. Eggers and Mr. Gridley were advised that on October 2, 1968, Electronics Technicians Robert Ritchie and William McCrimmon of the Tampa FCC office would arrive in Sarasota to investigate the complaint. This investigation was apparently the result of a letter written by Mr. Eggers' attorney to the FCC. Upon their arrival, Mr. McCrimmon inspected Mr. Gridley's station. He also observed the absence of interference to a TV set just a few feet from the transmitter. After approximately an hour and a half, Mr. Ritchie entered. He said that he had visited every house within two blocks of the Gridley residence, and that while a few isolated cases of interference were reported to him, in every case Mr. Gridley had quickly provided the necessary filters. Mr. Ritchie stated that "Mr. Gridley's cooperation in this matter appears to be outstanding". Tests were then conducted with the FCC inspectors observing Mr. Eggers' interference. Finally, a test was made with the FCC inspectors monitoring a TV set in their automobile located approximately 75 feet from Mr. Gridley's beam. With Mr. Gridley operating with the maximum legal power, there was no evidence whatsoever of interference on any channel. Upon leaving, Mr. Ritchie said that he could not make an official recommendation at that time and that

Nikola Tesla
Master of Electrical Energy

"Give me a lever long enough, and a fulcrum on which to rest it," Archimedes said, "and I will move the Earth." Nikola Tesla, a nearly forgotten man from a forgotten country, who was perhaps the greatest scientific genius in human history, needed no such prerequisites as Archimedes. Tesla succeeded in resonating the globe as though it were only a child's toy.

This man, who dared presume his power as significant as a God's, had humble beginnings. As the night of July 9, 1856 was drawing to its end, Nikola was born, the second son of a Serbian Orthodox clergyman in Smiljan, Lika, Croatia. (Croatia is now one of the six republics of Jugoslavia.) Djouka Tesla, Nikola's mother, was unable to read or write, yet had an excellent memory and literary facility. She could recite long passages from the Bible and thousands of verses of Serbian national poetry and was an accomplished seamstress. Nikola's father, Milutin, had had an excellent education, though, and had started a career in the military, only to enter the ministry shortly after he married.

Tesla forebears had given a long line of sons either to the military or the Church and Tesla's father intended Nikola to become a minister. The elder son, Dane, had a brilliant mind and the family expected him to bring them honor as a scientist or engineer. But Dane died when he was twelve years old, as the result of an accidental fall. It has been speculated by some writers that Nikola had to succeed in his brother's stead, perhaps because he felt guilty. This author thinks rather that Tesla's choice of vocation was the inevitable result of natural ability.

Young Nikola had an inherent mechanical aptitude which evidenced itself many times in his early years. When he was only four years old, he built a water wheel for the creek which flowed near his home. During his childhood he made many curious devices. One such was a popgun which fired a ball of wet hemp. He built and sold these to his fellow children until a rash of broken windows ended this enterprise. He turned to archery and went from bow-and-arrow to crossbow and then arbalest. He was fascinated by the idea of flying and when he was twelve years old, made an unsuccessful parachute jump from the barn using an umbrella.

He evidenced an original turn of mind from his earliest days. Once he noticed that after lightning struck from the dark masses of clouds that torrents of rain would fall, and decided that one might be able to control rainfall by controlling the lightning. Years later he had succeeded in producing artificial lightning, but was never able to convince the U.S. Patent Office that weather control might be possible.

In school his talents quickly led him to the head of his class, particularly in mathematics, a subject he favored. He detested resorting to paper and pen when it was so easy for him to solve any problem in his mind almost as quickly as the teacher had given it. This ability led to his being suspected of cheating and he was not given a passing mark. Nikola went to the director of the school and demanded an examination. The test was duly given and in the presence of the director and the teacher, Tesla solved problems far beyond his years. Suspecting that he had somehow gotten the answers to the standard examination, the officials departed from it to throw even more difficult problems at him, which he solved equally well. The astonished men could only acknowledge that Nikola Tesla possessed an astounding ability and passed him.

At fifteen Tesla continued his education at the Higher Real Gymnasium in Karlovac, Croatia, which corresponds to our college

level training. He completed the four year course in three years. During this time, he was living with an aunt and her retired army officer husband. The woman felt that Nikola was of delicate health and that heavy meals would have a bad effect on him. Tesla remembered this as the hungriest period of his life. While he was at Karlovac, he took many hikes along snow covered mountain trails. One day, he began rolling snowballs down a slope, trying to see how big he could get one. He succeeded too well and sparked an avalanche which roared down the mountainside and diverted itself harmlessly in a field, only just missing some farm buildings. Tesla was horrified at the near disaster he had created but wise enough to recognize that the tremendous power of Nature could be harnessed by relatively small applications of Man's power.

When he had completed his studies at the Gymnasium, his father had written urging him to take a hunting trip rather than return home. Tesla impulsively disregarded his father's advice and went home to find the area in the grip of a cholera epidemic. Worse than this was the elder Tesla's desire to see his son study for the ministry. Milutin Tesla was not wholly autocratic, however. He knew that if his son did not enter the church, he would be required to serve three years in the army. Nikola felt he was caught between Scylla and Charybdis, about to be crushed by alternatives he could not stand. Three years as a soldier seemed to him three years as an unthinking robot, compelled to the mindless disciplines of drill and routine. And a life in the ministry would leave him no time to learn Nature's secrets. Nikola had decided that he wanted to be an engineer.

The three years of undernourishment and the spiritual anguish he faced now so weakened him that he succumbed to cholera. For months he lay ill, one sinking spell leading to another. The family doctor finally announced that he could do nothing more for the boy and the family should prepare themselves for his imminent death.

Now the elder Tesla was facing his own crisis. One son had already died. He had pledged Nikola to the church, but if the boy died, the pledge would be unfulfilled. In anguish the father asked the dying son what he could do. Nikola whispered that he could get well if only he could study engineering and the despairing father quickly agreed. The deathbed crisis passed, Nikola's will strengthened and he began to recover. Tesla wrote in later years that no magical event had taken place, but rather his recovery had been because of a distasteful but potent medicine his mother prepared.

Subsequently the army declared the convalescing Nikola unfit for service and he was now free to pursue his goals. The elder Tesla's influence with other members of the family in the military for this decision has been suggested but is not definitely known. It is a fact that the father sent Nikola away for a year while the decision was being rendered. During this year Nikola amused himself with such fanciful projects as a proposed subterranean tunnel between Europe and America through which containers could be propelled by water pressure. Tesla quickly realized that drag would make the project unworkable, but nevertheless enjoyed such pursuits as a stimulus to his imagination.

In 1875, nineteen-year-old Tesla entered the Polytechnic Institute at Graz, Austria. In his effort to prove himself worthy of his father's reconsidered decision, he took twice the normal number of subjects and limited himself to less than four hours' sleep a night. At the end of the year, he returned home with the highest possible marks, fully expecting his father's praise. Instead his father disregarded the effort his son had made and criticized him for endangering his health. It was only years later that Tesla discovered that the dean of the technical faculty had written Milutin Tesla to say that Nikola was "a star of the first rank but will kill himself from overwork."

In his second year at the Institute, Tesla limited his studies to physics, mechanics and mathematics. During a demonstration of a Gramme motor/dynamo, Tesla remarked that the commutator sparking indicated power loss. His instructor, Professor Poeschl, patiently explained that the commutator was necessary to provide a direct current output. Tesla responded that by discarding the inefficient commutator and using the natural alternating current from the rotating armature, far greater efficiency could be attained. A hail of invectives greeted Tesla's conjectures, comparing them with such foolishness as perpetual motion machines. Since early experimental motors would not run,

it was assumed that the positive and negative cycles were cancelling one another. Some ac generators were used about this time, but only for resistive loads, such as street lamps. Everyone knew you could never get a motor to work on ac!

Though Tesla bowed before the authority of his professor, he could not get the concept out of his mind. Plan after plan was imagined and discarded. Tesla had had, for his earliest childhood memory, an amazing ability to visualize objects. When he thought of something it appeared before him, as real to him as any object in the external world. It took some time for the child to realize that other persons could not perceive these visualizations of his. The adult Tesla always said that he perfected his models in his mind, and that there they were so real that he could see signs of wear, and in the case of rotating machinery, could actually tell whether or not it might be out of balance. His visualizations were accurate to the thousandth of an inch; the piece parts he required did not need any trial-and-error machining. Years later, in America, the staff he had in his laboratory had a hard time keeping up with him. If his precise verbal instructions did not seem clear to a workman, Tesla would make a small, neat sketch on the handiest piece of paper. It is said that no matter what size paper Tesla picked up, his sketch was sure to be no more than one inch across, yet perfectly detailed.

This uncanny visualization, coupled with his amazing mathematical ability, certainly aided his inventive efficacy. Tesla had what we would call a photographic memory, and was able to quote—from beginning to end—Goethe's *Faust,* as well as a good deal of Shakespeare, and other classics. He committed the logarithm tables to memory, so that he would not have to waste computation time in reference.

Since he had heeded his father's advice for his second year at the Polytechnic Institute and had not taken as many classes, he rounded out his activities with billiards, chess—and poker. As he could visualize many moves ahead on the chessboard, it was only a short time before he had conquered all his fellow students. He then set about organizing a chess team which challenged other schools—the first known example of intercollegiate activities. His first poker game was a memorable one—the companion who took him to the game had promised a lamb for the shearing. By the end of the evening, the lamb had won everything. Then he amazed everyone by returning, to the cent, what each player had lost. For Tesla it was only a means of relaxation, not a profit-making venture. Many times he returned to the card table, and it was the same. Then one night luck or his own ability let him down. He calmly bet the tuition money he had received for the next year's study, and it was quickly gone. The game was over—but no one offered to return the money as Tesla had. This was a painful lesson about the nature of men and Tesla was deeply shamed that he had lost his parent's careful savings. Yet he could do only one honorable thing, and that was to confess all. He returned home, found his mother, and told her what had happened. Djouka Tesla sagely understood. Where his father would have scolded him for immoral activities, the mother knew that her son was obsessed. She gave him what little remained of their savings, telling him that he had yet to learn a lesson. When Tesla returned to the card sharps, they expected only more loot. Instead, Tesla, playing with steel determination, won everything. When the game was finished the players expected their money to be returned. This time, Tesla kept it. He had regained his tuition, and the money his mother had advanced him was returned. He made a solemn oath never to play cards again.

When he had completed his studies at the Institute, Tesla took a job at nearby Maribor with a tool-and-die works which was manufacturing electrical equipment. The money he saved enabled him to study a year at the University of Prague. Upon graduation, he travelled to Budapest, where a telephone central office was being built. The excellently-educated engineering graduate found that no responsible engineering position was open to him. Ironically, the job he was able to accept was that of draftsman with the Hungarian Government Telegraph Office. Some forty years later, he wrote that it was "at a salary which I deem it my privilege not to disclose!" He also recalled that, "By an irony of fate my first employment was as a draughtsman. I hated drawing; it was for me the very worst of annoyances." Yet Nikola Tesla could not do a job poorly and it was not long before his

ability was noticed and he was promoted to more responsible work and finally made chief electrician to the telephone company. At only twenty-five years of age, he found himself engineer-in-charge of an entire system.

It was to his liking. He found himself fully occupied during the day, limiting himself to a five-hour rest period, in which he tried to keep up with current technical journals, sleeping only two hours a night. At this time he invented the first "speakerphone", a loudspeaker apparatus with which a roomful of people could hear a telephone conversation. Tesla never bothered to patent it, though the company put it into service. Thirty years later, he remarked that it compared favorably with then-current loudspeaker designs.

All the while, his mind was constantly working on the concept of alternating current, but he had not yet solved the basic problem. Then the long hours of toil, welcome though they were to him, took effect and Tesla had a breakdown. Chief symptom of the unique nervous disorder he developed was a highly abnormal sensitivity. Tesla wrote: "I could hear the ticking of a watch with three rooms between me and the timepiece. A fly alighting on a table in the room would cause a dull thud in my ear . . . In the dark I had the sense of a bat and could detect the presence of an object twelve feet away by a peculiar creepy sensation on the forehead." Doctors pronounced the malady incurable, though they did not know what it was. As quickly as it had come, it went. While he was convalescing, his assistant, Szigeti, went with him for a walk in the park one afternoon. Tesla was pleased that the illness had not affected his memory and, looking at the sunset, began an appropriate quote from Goethe. Suddenly, before him, was the alternating-current apparatus he had thought about for so long. "Watch me reverse it!" he cried, throwing an imaginary switch. Szigeti feared that his boss had gone 'round the bend. Tesla calmed himself enough to explain. Evidently his mind had unconsciously completed the assigned task while he was ill. Tesla picked up a stick and sketched the circuit diagrams on the dirt path, explaining each detail to Szigeti. Tesla would use a two-phase ac in the field coils of his motor, which would produce a rotating magnetic field. This magnetic whirlwind would—by induction—pull the armature around with it. The armature would have wound coils closed on themselves, requiring no external electrical connection. Thus, in a blinding flash of inspiration, Tesla had grasped the answer. There would be no commutator to cause power loss; the only wear point of the motor would be the mechanical bearings.

Years later, a president of the American Institute of Electrical Engineering said: "The work of Nikola Tesla in his great conception of his rotary field seems to me one of the greatest feats of imagination which has ever been attained by the human mind."

The rotary magnetic field was more than an invention. It was a basic discovery, and it was this ability to perceive new insights into nature's wonders that set Tesla apart from other men. While those such as Edison made improvements on existing theory, Tesla forged ahead into an uncharted wilderness, where Man had not gone before. It was Tesla's gift that he could discover—but the gift contained tragedy, in that other men could not, or would not follow.

It was in February, 1882, that Tesla grasped the answer to the alternating-current problem. It would be six years before he would convince men that this was a revolutionary, wonderful new system. His immediate problem was more mundane—the job he had held was ended, as his employer had sold the business. Puskas, the employer, wrote a letter of recommendation for Tesla, which enabled him to get a job with the Continental Edison Company in Paris.

Tesla felt that the cosmopolitan city of Paris would give him the opportunity he needed and he swiftly took the job. Even more swiftly, he found that his employers were not interested in any "crack-brained schemes". Tesla tried to interest businessmen in his alternating-current system. Friends warned him that someone would steal his discovery, but that was hardly the case. Tesla could not even give it away.

In the meantime, his position with Con. Edison had been done in the usual flawless manner. Tesla was assigned as a roving trouble-shooter, and in 1883 was sent to Strasbourg, Alsace, then part of Germany, to straighten out an embarrassing situation. A new power plant had been built and Emperor William I was present at the dedication ceremonies. Unfortunately, the plant

had been wired by men who were less than adept at their job and when the master switch was thrown to activate the new lighting system, a short circuit blew out one wall, showering bricks and debris on the dignitaries. The Germans understandably would not accept the plant in its present condition and Tesla was dispatched to the rescue.

He soon put matters right, even in the face of German bureaucratic bungling. He writes of the "efficiency" of a simple matter of placing a hall light, in which the whole chain of command had to be consulted before the light could be installed at the very spot Tesla had suggested to begin with. When he was not taking time in matters of this sort, however, he was free to work on his own. He had brought some materials with him, and rented the facilities of a machine shop near the railroad station for evening work. There he built his first induction motor. Because he could vis*u*alize the final design so accurately, he did not need blueprints. He was a fussy worker, however, and the precise machining and polishing of the parts took time. The individual parts did not need cut-and-fit partial assembly but went together into a finished product the first time.

It was a dramatic moment. Tesla had thought the idea through in his mind, but it was new, it had never been tried before. Perhaps he had deluded himself, maybe it was only wishful thinking. He could only find out one way—he threw the switch. The motor hummed, the armature turned. Almost instantly, it had built up full speed. Tesla threw the reversing switch. The armature stopped, began to revolve in the opposite direction. It was clearly a success.

Tesla had made many friends in Strasbourg, impressed many people because of his efficiency and knowledge. Now he went to the mayor and various businessmen. Perhaps the sight of a working model would suffice where words had failed. But it was the same. No one seemed interested in what was the most significant commercial development in electrical engineering.

The despairing inventor returned to Paris, where another disappointment awaited him. He had been promised a substantial bonus on successful completion of the Strasbourg project. He had delivered. Now the managers of the works sent him on a wild-goose chase. The treasurer would pay him, only the treasurer said he did not have the authority to issue a draft; the operations manager understood, but he had not authorized the trip, etc., etc. Tesla gave his resignation in disgust.

Charles Batchellor, one of the company administrators who had been friendly toward Tesla advised him that he would have a better chance of achieving success in America. Batchellor was a close personal friend of Thomas Edison and gave Tesla a letter of introduction.

Once the idea was in Tesla's mind, it didn't take long for him to settle his affairs. He sold his possessions and books and bought a steamship ticket. On the way to the station where he would catch a train for the seaport, he was robbed. He managed to get to the docks but the steamship officials would not let him board without a ticket. He persuaded them that if no one showed up before departure to claim the reservation that they should accept his story as true. He arrived in America with four cents in his pockets, a book of his own poems, a couple of technical articles, some notes on a mathematical problem and on the design of a flying machine—and a wealth of inventive genius in his mind.

He presented himself to electrical wizard Edison quickly and angered the great man immediately by telling him of his alternating-current system. Yet Edison was quick to recognize the ability of the young immigrant and impressed by the letter Batchellor had written. Never one to ignore the knock of opportunity, Edison hired the well-educated and experienced engineer for eighteen dollars a week—hardly more than he paid the average mechanic in the shops.

Tesla was impressed on their initial meeting by Edison's forceful personality and recognized that the practical man had done quite a lot with no formal training. He wondered if his own educational process had been a waste of time. He was quick to learn, however, that it had not. Edison firmly believed in the trial-and-error approach to all things and much later Tesla wrote that "a little theory and calculation would have saved him ninety percent of his labour."

Tesla was initially assigned minor routine work but when he showed his talent and his dedication by working eighteen hours

a day, Edison soon trusted him with important tasks. One of the most significant concerned the steamship *Oregon*. Edison generating equipment had been installed on this most up-to-date liner of the day and worked well for many months but eventually broke down. Edison sent his lesser lieutenants to make repairs but they failed. The *Oregon* did not sail as scheduled and Edison was faced with financial and personal embarassment because of his equipment. In desperation he sent hardworking Tesla to try his luck. Working throughout one night with the assistance of a willing crew, Tesla rewound the armatures which had short-circuited. Leaving the ship in the early morning, Tesla met Edison and Batchellor, who had returned from Paris. When Tesla reported success, Edison remarked to Batchellor that Tesla was good as Batchellor had said, and "indeed, he's even as good as he thinks he is!"

But their good relationship was soon at an end. Tesla was already discomfitted by Edison's refusal to consider an alternating-current plan. It is true that Edison had made a $2 million investment in New York City on a dc distribution system. Naturally he did not want to see this expenditure threatened.

The final blow came as the result of a statement Edison made to Tesla concerning some research problems. Edison told him it would be worth fifty thousand dollars if he could come up with the answers. In all, Tesla's improvements led to twenty-four new dynamo designs utilizing highly efficient short field-core magnets, some new automatic controllers, and several patents taken out in Edison's name. Tesla had delivered the goods and eagerly awaited the promised bonus. When it was not forthcoming, he asked the great man and was told: "Tesla, you just don't understand our Yankee humor."

It was Spring, 1885, and he had been with Edison less than a year, but he could no longer go on. As Con. Edison had cheated him in Europe, so he was led down the garden path in America by Edison himself. Tesla's reputation had developed well, and some promoters approached him with the idea of starting a street and factory lighting company under his name. Tesla offered his alternating current system to them, but they rejected it in favor of quick profits in this utility venture. Tesla agreed to develop a practical arc lamp for shares in the company. For about a year he worked at a very small salary, producing all the equipment the businessmen had asked for, and taking out several patents. When the system was well under way, Tesla was given stock shares and was quickly manipulated out of the company. He found that his share certificate was worth very little. The United States was undergoing a depression and Tesla was without income. His former associates, not content with having eased him out of the company, new made spurious claims about his unreliability. And Edison certainly had nothing good to say about him.

Tesla underwent such a period of hardship during the next year that he would never discuss it in later life. It is known that he did occasional electrical repair jobs, when he could find them, and that he worked as a common laborer. During the winter of 1887, Tesla was working as a ditch digger. The crew foreman, a former stock broker who had lost everything in the market, became interested enough in Tesla's theories to introduce him to A. K. Brown of Western Union Telegraph. Brown and an associate financed a laboratory for Tesla, and organized the Tesla Electric Company in April, 1887. Tesla's lab was at 33-35 old South Fifth Avenue (later West Broadway) and not far from the Edison works. The models Tesla now built were identical to the designs he had conceived five years before. In all this time he had made no notes—the concepts were firmly locked in his memory. By October of that year, Tesla had filed for a patent. He wanted a single patent for the discrete elements which comprised his system. The U.S. Patent Office was horrified at the idea of such a sweeping omnibus approach. They insisted on a breakdown to seven separate sections. By the end of the year he had filed for and received thirty basic patents.

The scientific world which had ignored Tesla for so long now could not contain its amazement. As the import of his system was grasped, he was praised as the scientific genius of the age. The lecture he delivered on invitation to the American Institute of Electrical Engineers on May 16, 1888, is a classic of the electrical engineering field. The theory and practise he presented are the basis of the system we still use today.

In one stroke he accomplished an engineering breakthrough of such magnitude that no comparable development has been presented since. Tesla was on the crest of an inventive wave that would last for thirty years.

Fortunately for Tesla—and for the world—the man of commerce who could bring this scientific feat out of the laboratory and into the everyday world of engineering practise approached. This was George Westinghouse, inventor in his own right, and head of his own company. Westinghouse was not committed to direct current as Edison was. In Tesla's system, he saw the revolutionary means of long-distance power transmission that would reap profits such as Edison's plant could only wish for. Westinghouse offered Tesla one million dollars for the rights to the group of patents, which now numbered forty. Tesla agreed, provided that a royalty based on equipment produced was also paid. A conservative estimate was later made that Tesla should have received an additional $12 million in royalty payments.

This dynamic duo was the worst possible threat to the Edison system. What Tesla—the man of vision—lacked in financial awareness, Westinghouse—the successful entrepreneur—could supply. The United States was leaving a phase of depression and entering one of explosive capitalistic growth, in which giant industrial empires were born. Westinghouse, in his eagerness to make the most of the Tesla system, expanded his corporation by consolidating a number of smaller companies and also by attracting much outside capital. The time came, however, when Westinghouse's board of directors overrulled him on the matter of royalty payments to Tesla. Even though there was a legal contract in which the payments were stipulated, the board argued to an unwilling Westinghouse that such payment would seriously endanger the stability of the corporation. Further, if Westinghouse insisted on honoring the contract, much of the outside capital would be withdrawn. As an inventor himself, Westinghouse understood the justice of the royalty payment; as a businessman, he could not bear the thought of the empire crumbling. He went to Tesla and explained the situation. Tesla had become a close personal friend of Westinghouse and understood the problem. Further, he was more interested in seeing his system operating on a successful basis than in collecting a payment legally his, which would wreck any chance of that system's development. Tesla tore up the contract and the Westinghouse empire was saved.

Tesla had had to give half of his million dollar initial payment to Brown and his associate, but the half which was left served well enough to maintain the most splendid research establishment seen in America at that time. Tesla embarked on a program of research that would have broken most men. He began his monumental studies into high-frequency phenomena, and at most fortunate time.

The Edison faction had not been inactive during this period and in a calculated campaign to destroy the alternating-current disciples, began a whirlwind of adverse publicity. Edison and his friends gave Sunday afternoon demonstrations on the evils of ac by electrocuting cats and dogs for the edification of visitors.

Edison wrote: "Just as certain as death Westinghouse will kill a customer within 6 months after he puts in a system of any size. He has got a new thing and it will require a great deal of experimenting to get it working practically. It will never be free from danger."

A propaganda campaign of immense proportions arose. Most of the so-called scientific proof of the horrible dangers of ac erupted from Edison's laboratory in West Orange. Misleading statements were issued to the press. Pamphlets were distributed, warning the people that it would soon be a matter of taking one's life in his hands to merely walk the streets, constantly at the mercy of the lethal high-tension wires. A further suspicious fact is that a former laborartory assistant at West Orange, H. P. Brown, began lobbying and lecturing for the passage of a bill in the New York state legislature for the provision of death by electrocution.

Such a bill was passed in 1888 and H. P. Brown, now a consultant to the state, authorized the purchase of three Westinghouse alternators to be installed at Sing Sing Prison. George Westinghouse protested this particular use of his equipment, but the authorities pointed out blandly that dc generators could hardly provide the high voltages necessary. On August 6, 1890, con-

victed murdered William Kemmler was to be put to death in a secret ceremony. The engineers who had installed the electric chair had been perhaps more frightened of it than was necessary. It was reported that the power was insufficient to cause death. Repairs had to be made and the execution repeated, resulting in "an awful spectacle, much worse than hanging . . ."

Meanwhile, Tesla had not been idle. He had, of course, selected 60-Hertz operation as best for commercial power applications. Indeed, he had opposition from Westinghouse engineers at the Pittsburgh plant where the new apparatus was being developed. They preferred a 133-Hertz system, partly because of decreased cost of core materials needed at the higher frequency. Tesla left in disgust, even though Westinghouse was able to offer him $24,000 a year salary. Shortly thereafter, the engineers did select our familiar 60-Hertz system as the standard. Tesla remarked that the year he spent in Pittsburg was wasted in minor design problems and that he was not free for creative work. In the next four years, he was granted 45 additional patents on polyphase current distribution.

His researches into higher frequencies had led him to the discovery that as the frequency increased, less and less iron was necessary in transformer cores. Utilizing conventional rotary dynamo technique, he built devices which produced up to 10,000 Hertz. The next step was the production of even higher frequencies and the development by him of the air-core high-frequency transformer known and loved by all as "the Tesla coil". Two decades later, F. W. Alexanderson was developing high-frequency ac dynamos for high-power wireless transmitters for the government along the same lines.

Incidentally, Tesla's choice of 60-Hertz operation made possible cheap electric clocks, driven by synchronous motors, a fact he pointed out freely.

Along with the high frequencies Tesla was now producing, were also high potentials, so much so that conventional insulating methods were ineffectual. It was at this time that Tesla produced the technique of oil immersion, which had great commercial importance. He had soon reached the practical limits of frequency from rotary dynamos. Now he was exploring the field of resonance phenomena. He developed the technique of electrical tuning in 1890, one of the basic principles of radio.

Utilizing Lord Kelvin's theory of the damped oscillation wave of a discharging condenser, Tesla developed means of charging a condenser by low voltage, then using the "disruptive discharge" through the primary of his air-core transformer, deriving very high-frequency oscillations and extremely high potentials in the output. He discovered the heating effect in the human body of the high frequency currents and thereby laid the principles for medical diathermy. Here was another pioneer discovery for which he took no patents nor credit.

He lectured once more before the American Institute of Electrical Engineers in May 20, 1891, on the subject of high frequency currents, and demonstrated a variety of phenomena. With apparatus then, he was able to achieve a spark discharge of over five inches, indicative of a potential in excess of 100,000 volts. The induction coil he used was energized from a generator of his own design working at 20,000 Hertz. He described the various discharge phenomena exhibited under varying conditions of potential and frequency. In his research he had discovered that the nerves of the human body could not react to currents higher than 700 Hertz. He recognized that high voltage as such was not lethal, as he had taken the high-frequency discharges of his larger apparatus many times without ill effect. Partly it is because of "skin effect", in which the high frequency tends to travel across a surface of a conductor. Also the output of Tesla's apparatus had a low current density. He wrote that slight changes of potential, current, and frequency could work together to form a lethal shock.

He said that the surest way to electrocute a person was to subject him to sustained direct current, but that the most painful means of killing would be to use a low-frequency alternating current. It is conceivable that a high-power, high-frequency current could kill swiftly and painlessly. But his demonstrations before the Institute were clear proof that alternating currents, as such, were quite harmless. Tesla repeatedly put himself into the high voltage secondary circuit of his coil, in the process of lighting bulbs of his own design, with no discomfort.

Part of the awe-inspiring show was the fact that the forms of illumination Tesla was demonstrating had never been seen before. Instead of the ordinary Edison bulb for light, Tesla was using ordinary wires in normal atmospheric pressure to demonstrate luminosity effects. He had vacuum lamps, lamps with other gases, lamps with extremely high internal pressure—and most of the above had but one terminal. Others had none at all!

The production of a practical means of commercial power and now the development of a whole new spectrum of alternating currents—both within three years—established his reputation firmly with the scientific community. All at once he had more offers for lectures, after-dinner speeches, demonstrations and consultations than he could cope with. One of the problems was that his high sense of intellectual honesty and originality required him never to duplicate the material in a lecture; thus each appearance of this prodigal genius before the public was a unique event.

He was invited to lecture before scientific bodies in England and on the Continent. In February, 1892, he gave another lecture on high-frequency currents before the Institute of Electrical Engineers in London. Sir James Dewar asked Tesla to repeat the lecture before the Royal Society. Tesla had other plans and demurred, but Sir James took him to Michael Faraday's chair and plied him with the remaining private stock of whisky which had belonged to that earlier genius of electrical invention. After such a singular honor, Tesla could do no less than agree.

While he was touring Europe he received word that his mother was gravely ill. He arrived at her home in time and was able to talk with her that day. She died during the night. The strain of rushing to her deathbed caused a patch of hair on his head to turn white overnight, but a month later it had regained its natural color. His father had died years before, while he was still a student.

When Tesla returned to America he realized that his social success had cut into his research time tremendously and he turned away from all such engagements in the future, preferring to devote himself to useful work in the laboratory. During this period he experimented with such diverse items as high-frequency currents, mechanical oscillators, X-rays, and astronomical studies. He prepared a large exhibit for the 1893 Columbian Exposition, where Westinghouse had won the contract to furnish power and lighting equipment. During frequent demonstrations at this World's Fair, Tesla passed one million volts of high-frequency electricity through his body, to turn copper plates molten or to light special bulbs of his own exotic design. The public was thoroughly convinced that ac was not the danger Edison and his followers claimed.

The final blow the dc faction received was the harnessing of Niagara Falls. The child Tesla, having seen a picture of Niagara and perhaps influenced by that first toy waterwheel, prophesied that he would someday make the falls work for him. Now that dream was to come true. A charter for developing power at the Falls had been granted in 1886 and in 1890 Edward Dean Adams, head of the Cataract Construction Company, organized the International Niagara Commission. Lord Kelvin, the famous British scientist, was made chairman of this body, which was to determine the best method. A prize of $3,000 was offered for the best plan submitted. Tesla was frantic to toss his hat in the ring but George Westinghouse pointed out that the prize would be insufficient payment for value received and persuaded Tesla to persevere. A further complication was that Kelvin favored direct current. However, in 1893, when none of the major manufacturing concerns had submitted plans to claim the prize, the commission asked for bids. By now the Edison faction had capitulated and paid for the rights to utilize the ac patents. Westinghouse's bid for the generating plant was accepted on May 6 and the by-now General Electric Company, Edison's empire, was chosen to build the transmission line to Buffalo, twenty-two miles away. After the completion of this project, which was described as the "most tremendous event in all engineering history," Kelvin admitted that alternating current had many more advantages, and further stated that "Tesla has contributed more to electrical science than any man up to his time."

Ironically, during this period of commercial development of the polyphase ac system, Tesla was referred to as an imitator by the British press, which claimed that he

had used as the basis of his system the apparatus of a physicist at the University of Turin, Professor Galileo Ferraris. It has been proven that Ferraris first presented a paper on "electrodynamic rotation" in 1888, six years after Tesla's discovery of the rotating magnetic field, and indeed, several months after Tesla's application to the U.S. Patent Office. Ferraris had developed an alternating-current device as a demonstration of circularly polarized light and stated specifically that the principle behind his model could never be developed as a practical power unit. Yet chauvinistic English publications, which had received notice of the Tesla system, ignored it.

In 1891, another pretender to the throne arose, in the person of Dolivo Dobrowolsky, at the Frankfurt Industrial Exposition of 1891. Dobrowolsky claimed the invention of the first practical ac motors, and later reduced his assertions to a greater efficiency of his three-phase motor than that of the original two-phase Tesla induction motor. However, the chief engineer of the project, C. E. L. Brown, completely smashed Dobrowolsky's claims by writing to the *Electrical World* that "the three-phase current as applied at Frankfurt is due to the labors of Mr. Tesla and will be found clearly specified in his patents."

Part of the problem during this period of massive technological change was that the lines of communication and publication of new inventions were very slow. And there were those that put forth fradulent claims, so that they could reap the rewards. But at the same time, errors of fact have been made by writers too lazy to do proper research.

Finally and unequivocally, Tesla was granted the credit due him, by scientists, engineers, and editors throughout the world. It is certain that the many persons who saw Tesla's demonstrations at the Columbian Exposition would not soon forget him. By 1900 there were many usurpers and infringers on the Tesla patents. The Westinghouse Co. took about twenty suits to the courts and the Tesla patents were upheld in every case. Judge Townsend of the U.S. Circuit Court of Connecticut in September, 1900, wrote: "It remained to the genius of Tesla to capture the unruly, unrestrained and hitherto opposing elements in the field of nature and art and to harness them to draw the machines of men . . . he first conceived the idea that alternations might be transformed into power-producing rotations, a whirling field of force.

"What others looked upon as only invincible barriers, impassable currents and contradictory forces he seized, and by harmonizing their directions utilized in practical motors in distant cities the power of Niagara."

After his European and American lecture tours and his triumph at the World's Fair, Tesla withdrew from public and social life. The next two years were full to bursting. Induction coils had led him from the curious phenomena of high-frequency to the realization of the nature of electrical resonance. He planned to develop wireless communication through the earth by means of his air-core transformers. Soon he progressed to the notion that power itself could be transferred. Even working eighteen hours a day, he had not enough time for the ambitious program he undertook. During this period he discovered, independently, X-ray phenomena of the type that Roentgen would soon announce. But Tesla never claimed his system was similar to Roentgen's. All he noted at this time was a type of "very special radiation". With it, he was able to get shadowgraph pictures through a human head—at a distance of 40 feet!

He turned his attention to atmospheric phenomena and declared that the *aurora borealis* was caused by expulsion from the sun of particles of high electrical charge. Professional astronomers laughed at such an idea; after all, they knew that the sun was 93 million miles away. He further convinced them of his eccentricity with a casual statement about the "dozen or so" planets of the solar system. Then he announced his detection of mysterious rays bombarding the earth, of hundreds of millions of volts in energy. A decade later, in 1909, W. H. Pickering announced the probability of a trans-Neptunian planet. In 1930, such a planet was discovered photographically and named Pluto. Robert Millikan announced the existence of cosmic rays in 1926 and thereby won a Nobel Prize in physics.

The above were merely side interests. His main curiosity was in resonance phenomena. Aside from electrical oscillations, Tesla had developed several interesting mechanical

resonators, testing their low frequency mechanical vibrations and their effect on the human body and on various materials. Noticing the invigorating effect of the vibrations, he was induced to construct a small massager for the barber of one of his assistants—the ancestor of the same massager the barbers of today use. Another of his vibrating machines consisted of a platform on which one could stand. The platform was connected to a large motor which could be adjusted for different rates of vibration and which created invigorating sensations in the human body. Author Sam Clemens had become a close friend of Tesla and visited the inventor's laboratory many times. Tesla admired Clemens and claimed that one of "Mark Twain's" books had hastened his recovery from a youthful illness. One day, Clemens tried the platform and found it so refreshing that he would not get off, even at the urging of his friend, Tesla. Suddenly he stepped down and demanded petulantly to know "where it was". Smothering a smile, Tesla pointed the way to the rest room, where Clemens hastened. At certain rates, the curious platform had an irresistible laxative effect.

Another of Tesla's mechanical oscillators had more serious ramifications. Tesla had noted that gentle application of power at the natural resonant frequency of a material would set up strong vibrations within it, just as it is possible for an opera singer's voice sustaining one note to sometimes shatter glass. Tesla attached his puny device to a strong vertical steel girder in the laboratory. It seemed improbable that any significant action would occur. He activated the device, which was described later as small enough to slip into one's pocket. It was automatic in operation, in that it would "hunt" for the natural frequency of the substance it was attached to and then lock in step and reinforce the resonant wave. At first, nothing could be noted in laboratory. However, in other parts of Manhattan Island matters were quite different. The strata of sand beneath the surface transmitted the vibrations exceeding well, whereupon they reflected from the granite layer of bedrock. Since the vibrations were sustained by the mechanical oscillator, the power of the waves constantly grew. Shortly, windows were cracking, plaster falling, furniture

moving wildly about. The man-made earthquake began at some distance from the laboratory and slowly moved in toward the source centre. By the time the shock wave impinged on Tesla's building, local police were deluged with reports. Officers were sent to the laboratory. When they entered, they found Tesla smashing the oscillator with a sledge hammer. He had realized what must be happening and taken the swiftest action necessary to cease his experiment. The police had been right in believing Tesla to be involved—after all, anyone who could make lightning in the laboratory must be responsible for other strange occurrences.

Tesla later calculated that his innocent-appearing device was capable of much greater damage. He never released specifics on its construction, prudently, and never resumed such experiments. Later he claimed that with it he could have destroyed the Brooklyn bridge within an hour, or "could now go over to the Empire State Building and reduce it to wreckage in a very short time." At least one published estimate of the time necessary was fifteen minutes! Lest someone think this an idle boast, recall that soldiers break step when marching across a bridge. Further, the infamous "Galloping Gertie", a bridge across the Tacoma Narrows built in 1940, showed all too clearly the result of destructive vibration. When completed, it was the third longest suspension bridge in the country. Four months after its completion, a wind storm, with gusts to 42 mph, well within the calculated safety limits, started erratic vibrations in its span. After four hours, waves of thirty feet were passing along. Then it began undulating from side to side. Four more hours saw 600 feet of the centre span plunge into the Narrows. The 1000-foot side spans followed. Anyone who has seen the film of this bridge swinging from side to side in a mad dance will acknowledge the effects of internal vibration.

On the night of March 13, 1895, catastrophe of another sort hit the Tesla laboratory. A fire razed his building, destroying several years' work, most of Tesla's awards and momentos, what notes he did keep. Fortunately his prodigious memory kept the loss to a minimum, but almost all his experimental equipment was lost. He opened a new laboratory at 46 E. Houston Avenue in July of that year and went on with his work.

By September of 1897, he had filed and received U.S. Patents 645,576 and 649,621 —which have been called the fundamentals of radio broadcasting. He was now ready to demonstrate for the public his new wonders. Always the showman, he booked Madison Square Garden and put on a demonstration of what we would refer to as a radio-controlled boat. He called his remotely-controlled devices "telautomatons". Thousands of people saw a small craft with antennas which could be ordered about at will. Tesla had had constructed an immense tank, in which the boat was placed for the demonstration. The model craft was controlled by a Tesla wireless transmitter and could follow its orders even under water, for it was also a submarine!

This alone would have been sufficient to win him undying fame, had he pursued it monomaniacally. But for Tesla it was not yet enough. His idea of good transportation was a vessel which did not have to take its fuel along, but could receive it as electric power via a broadcast system. Once he had achieved the means of sending signal power, he believed that he could transmit power enough to drive ships and eventually aircraft.

Tesla had advanced in his research to the point where he was able to build a 5 million volt oscillator in his New York laboratory. He was already using lower-potential oscillators as a drive for wireless fluorescent lamps which lighted the laboratory. The big job was used to test his theories of energizing the earth to transmit power by conduction. He recognized that he had reached the limits of safe operation within the confines of the city and proceeded to set up a new laboratory near Colorado Springs. Local entrepreneur, Leonard E. Curtis had promised land and all the electric power he needed, reasoning that a great scientific name such as Tesla's would bring a good deal of attention to the community.

The new laboratory was at an ideal location. Colorado terrain is a great producer of natural lightning and Tesla was able to devise equipment which would record the magnitude of the blasts. He determined that standing waves were set up by the lightning bolts—as storms moved further away, the recorder invariably showed peaks and troughs in the received energy. This further

substantiated his theory of earth conduction. The additional data he obtained aided his production of artificial lightning, perhaps with a view to controlling the weather, as he had fancied long before. However, his present interest was the development of practical wireless transmission of power in commercial quantities. Tesla's apparatus depended for its effect not on electromagnetic radiation, as some have mistakenly believed, but on massive electrostatic action. Indeed electromagnetic dispersal of power was wasteful, in Tesla's system. His system used a "magnifying transmitter," which was a gigantic Tesla coil, driven by thousands of horsepower. The secondary was a quarter-wavelength coil, one end grounded, the aerial portion attached to an immense copper electrode. Once the generator attained full power, the aerial electrode acted as one plate of an artificial condenser, the ground point being the other. In this way, Tesla pumped enormous quantities of electricity into the earth. Some 200 kw was the rating of his Colorado installation.

While weeks of labor turned into months, and the barn-like building he had had erected became stuffed with equipment, his workers had no clear idea what exactly was to happen. At last all was complete and Tesla explained to them; there was a nervous exodus for the door. Only one old assistant dared to stay. Tesla stood outside, conveying his orders to Czito, the assistant, by hand signals. At first, the generator, which drew its power from the commercial ac mains, was only energized a little. Then the power was slowly increased. With each step up in power, changes occured at the copper aerial electrode, First there was only a violet corona discharge. Then, as more power was fed to the system, sparks began to snap and hiss. At the half-power point, bolts of raw electricity leapt from the electrode. As the system neared full power, artificial bolts of lightning, thick as a man's arm, snapped forth, fifty, a hundred, then almost two hundred feet in length. This secondary effect was natural, a sign that the electrostatic equilibrium was being disturbed. When the system stabilized, the lightning would end. Then, as they reached full power, all activity ceased. Tesla ran inside, saw that he was no longer receiving power from the commercial lines. He called the power company.

"You've ruined my experiment," he told them.

"And your experiment has ruined our station," was the reply. "You overloaded the generator and it caught fire."

Humbled, Tesla took Czito to help him set things right at the power station.

It has been stated that Tesla failed in his attempts to transmit power, but this writer believes that other factors became predominant. There are pictures extant of Tesla's apparatus in operation. In one instance, he demonstrated for the press the new system. A receiving circuit was set up twenty-six miles away from the "magnifying transmitter" and 200 50-watt incandescent bulbs were lighted to full power; this, with the transmitter at a low output. Tesla claimed a 95% efficiency for the new equipment.

Tesla was fully satisfied with his results and evidently the U.S. Patent Office concurred, as they issued a number of patents on wireless power transmission. However, when Tesla returned to New York to raise capital for a commercial system, he was unable to. Investors could not see what profit they could make from a system where anybody anywhere could use the power fed into the earth. Let it be said that practical financial considerations of this type were never Tesla's strong suit. The single greatest flaw of this scientific Jove was complete lack of a hard-headed business sense. He further compounded his errors by an overly generous nature.

Those who infringed on his patents were never attacked by him personally, as he considered time taken in such undertakings as wasted. He believed he could never run out of new ideas and inventions. He preferred the wealth of discovery in the laboratory. Also, his great goodwill led him to the naive expectation that, when he had produced a means of improving the human condition, he would be appropriately rewarded by a grateful humanity. His polyphase power distribution system had already improved man's lot by substituting cheap electrical power for manual work in many areas. His new system would make electrical power available in the most remote, inaccessible and impoverished places.

Tesla, returning to New York City in the summer of 1900, found himself in the same situation he had been in in 1882—he had

a wonderous discovery, but could not interest anyone in it. The financiers asked if he had not something else they could capitalize on. He stated that he could adapt his system as a "world broadcast plant". With it, he asserted, he could provide "interconnection of existing telegraph and telephone exchanges *all over the world;* establish a secret and non-interferable government communication service; maintain universal distribution of news; establish a world-wide system of musical distribution; maintain accurate time signals to clocks everywhere; provide full facsimile transmission; send accurate navigational signals"—among other possibilities.

"A cheap and simple device, which might be carried in one's pocket, may then be set up somewhere on sea or land, and it will record the world's news or such special messages as may be intended for it," wrote Tesla, concerning his "World-system".

The men of money were skeptical; Tesla promised much. Still, he had delivered on his claims before; the polyphase ac system in general use now was silent testimony to this man's genius. Then J. P. Morgan made a gift to Tesla of a sum which was never disclosed, but estimated to be from $150,000 to twice that amount. James S. Warden, manager of the Suffolk County Land Company made available to Tesla two hundred acres of his company's tract at Shoreham, Long Island, about sixty miles from New York City.

A large brick building was soon erected and a great, wooden tower was being built. An all-wood structure was specified, because of the enormous voltages the plant would handle. Stanford White, the eminent architect of government buildings of that era, provided the plans for such a structure. The tower was some 187 feet high, and many people snickered, because they knew such a wooden tower could not stand, or if it did, would not be able to resist high winds. A torus-shaped copper electrode of copper, 100 feet in diameter, was to top the tower. This was later changed to a hemispherical shape. Needless to say, the equipment being installed—most made to order—the tower itself, and the cost the copper electrode and changes engendered took all the money Tesla had. The smaller investors stood by, waiting to take their cue from Morgan. That financial baron had

made a good deal of money on the General Electric Company, whose financing he had accomplished, and the others reasoned that if he was backing Tesla again, they would follow. They did not know that the sum was a personal gift, not a business investment. When Tesla ran into financial difficulties and Morgan did not rescue him, rumors arose that Morgan had withdrawn his support in dissatisfaction. Tesla was unable to raise further capital and the "World-system" went down the drain. A couple of personal friends extended sums, which Tesla used to pay off creditors.

It may be argued that the system was a technological failure, that Tesla was unable to produce the results he had claimed. However, his earlier experiments in Colorado had been sufficiently practical to win him U.S. patents. It is hardly necessary to say that the Patent Office does not grant patents on conundrums such as perpetual motion machines.

Tesla wrote of this failure: "My project was retarded by the laws of nature. The world was not prepared for it. It was too far ahead of time. But the same laws will prevail in the end and make it a triumphal success."

Nevertheless, Tesla did not regain his stature as creator after this episode and his twilight years were taken up with ever smaller practical projects and ever more grand dreams and theories. His next major enterprise was the successful development of a bladeless turbine, another revolutionary idea. The Tesla turbine used a rotor composed of a series of smooth discs. Steam entered through center porting and flowed in spiral lines around the discs, dragging them along by virtue of viscosity and adhesion. The first experimental model, built in 1906, was six inches in its largest measurement, weighed about 10 pounds, and developed 30 horsepower. But it was another case of being too much ahead of time and revolutionary. Though the high cost of machining the conventional turbine bladed rotor made the Tesla approach attractive from a cost viewpoint, the conventional turbine was already highly developed and accepted.

In 1911, Tesla adapted the radio-control apparatus he had developed for his 1898 submarine demonstration to an airplane and presented his plans to the War Department, where the scheme was laughed at. Of course, this was the same period when Robert Goddard, the American father of modern rocketry, was ridiculed as a crank by the military savants of this country. By 1936, the aging Tesla had completely recanted in his idea that devastating weapons would make Mankind turn away from war; he claimed that he had conceived a 'death ray,' but would not give his calculations to the government. Fantasy, some say. Yet it is a fact that the Federal Bureau of Investigation impounded his papers when he died in 1943, and for all this writer can discover, still has them. The death ray would have been only a defensive weapon, because it required staggering amounts of electrical power. It would have secured a country against enemy air attack. As early as 1917, Tesla had thought about this problem and had described the possibility of apparatus which could broadcast short-wave impulses and receive reflected waves which would be displayed on a fluorescent screen—radar, in short.

Fortunately, Tesla wrote a good deal in later years. Gernsback's "Electrical Experimenter" published a series by the scientist starting in 1919, which gives some valid

biographical data and a good review of his discoveries and plans. Tesla also wrote on diverse subjects: van de Graaf generators, Servian poets and translations of their works, the compass, the moon's rotation, woman's role in future society. Perhaps the writing that caused the greatest reaction from the public was "The Problem of Increasing Human Energy," in Century magazine, June, 1900. Instead of a dry scientific dissertation, Tesla took a philosophic approach, derived in part at that time of a mechanistic view of Man. In this massive article, he discussed such topics as public health, morals, diet, the outlawing of war, his telautomatics and their potential use, harnessing solar energy, the iron industry, the coming age of aluminum, new power sources and prime movers, wireless and the secret of tuning, and the practical possibility of interplanetary communication.

Concerning the latter, Tesla had claimed that he had received radio-type signals which could only have come from outer space. Conventional people, both scientists and laymen, laughed. Marconi claimed the same results. Many years later, Project OZMA's radio telescope began probing the stars for intelligent signals. And the recent International Astronautical Congress in Rome heard a paper which reviewed the findings of Tesla, Marconi and the Scot, David Todd.

In 1912 the Nobel prize in physics was awarded jointly to Tesla and Edison. Though he could have sorely used the $20,000 prize money, he refused the honor. Tesla called himself a discoverer and Edison an inventor. "Placing the two in the same category would completely destroy all sense of the relative value of the two accomplishments," he wrote. By a great irony, a few years later friends persuaded Tesla to accept an honor presented by the American Institute of Electrical Engineers—the Edison medal. In 1936, the Yugoslav government awarded an honorarium of $7,200 a year to the aging scientist.

On January 7, 1943, Tesla passed away, ignored by the world he had helped to energize. He had once written: "The opinion of the world does not affect me. I have placed as the real values on my life what follows when I am dead." A prophetic statement—for less than a year after his death, the United States Supreme Court rendered a decision that the Marconi radio patents were invalid, on the basis of prior work by Tesla and others. Had this significant decision been reached during Tesla's lifetime, he might not be all but forgotten today. Every school child knows of Edison. Most people have heard of Marconi—but the name "Tesla" raises blank stares. Of course, much has been written about Tesla concerning his eccentricities, his strange beliefs and habits—sensation-mongering that has led attention away from his accomplishments. However, the summation must be that his was a brilliant career—he led the way for the world during the peak of his abilities, and as his influence ebbed, he pointed to future realizations for others. His successes are beyond dispute. His failures may yet yield practical results. ■

ATTENTION

Last minute news! W3EFI and WA5AXW/3 are sending up a balloon containing a ½ watt transmitter sending a series of dits. The unit will go to 50,000 ft. and will be launched February 26th. Frequency will be 28.250. Send signal report and time/date heard to: Ken Hollan, W3EFI, Fairhaven, Maryland, 20796. Future balloons will include telemetry and more sophisticated equipment. Hopefully we will hear more from these enterprising hams.

Go Mobile!

Joe Hannigan WB6ACM
887 *Islay* 3
*San Luis Obispo, CA*93401

So you've decided to go mobile. Have you considered the problems you may face when it comes time to put the rig in the car?

Have you decided on your equipment? Let's think about it for a while.

High power is not too practical for mobile operation. A medium powered transceiver will work around the world. Also, the lower power adds a challenge to the game, and saves batteries and generators as well.

Unless you have one of the larger luxury cars or have no family, you'll want a unit that takes up as small a space as possible (some 300 watt units take up less than a cubic foot).

If you're not a VHF'er, you'll want a rig that will work on 80 through 10 meters and an antenna that covers those bands. Long whips may cause a problem with mounting and can be dangerous when you go around a corner (it might wrap around something or someone)!

Now, let's see what problems lurk ahead.

The first step in the installation is to mount the antenna. A body mount should be used, because it will give greater efficiency by providing added height. Place the mount on the top of the left rear fender. This position will give a good radiation pattern. A better pattern can be achieved by mounting the antenna in the center of the roof, if you have the courage.

A bumper mount can also be used, but a poorer ground may result.

The coaxial cable should be run from the antenna mount to the position chosen for the transceiver, usually be under the dash.

Take care to protect the cable from fraying when it passes through holes in the body of the car by installing grommets.

The transceiver should be mounted as far toward the firewall as possible to give the passengers as much room as possible. This saves the equipment from being kicked when they enter the car.

Make sure the installation is as vibration proof as you can make it so that the printed circuit boards won't be broken and other parts shaken loose.

The power supply is next. It should be placed as far in front of the engine and radiator as possible. Power transistors generate a large amount of heat, and need to be kept cool. Position the supply so it will be in an area of maximum air flow. It unit should be mounted flush with the body of the car to insure a good ground, and to allow the body to act as a heat sink.

Run the cables from the power supply to the transceiver, but be sure to remember the grommets! Keep the leads as short as possible.

Remove the fuse from the power supply and connect the battery cables. These cables should be as short as possible (no more than three or four feet), or poor voltage regulation will result. Put the fuse in the supply, and you're almost ready to go on the air.

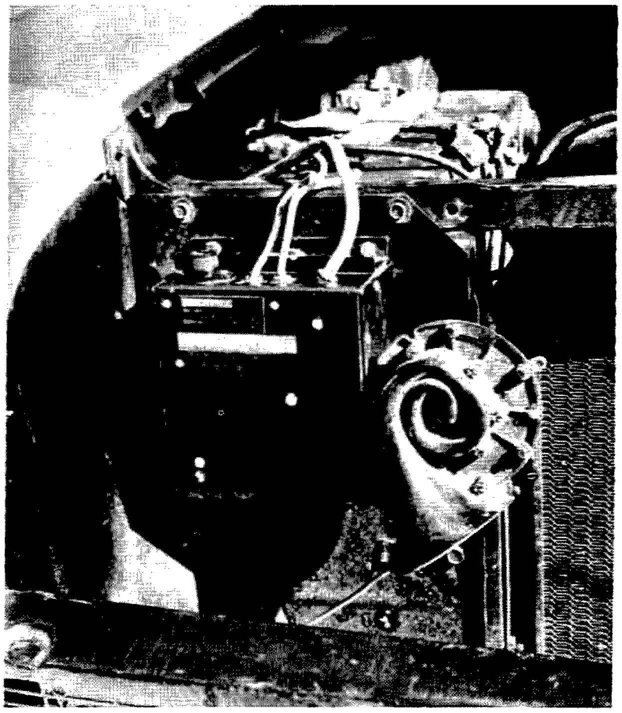
You still need a speaker, but most cars have one mounted for the car radio. Clip the speaker's hot lead and install an spdt toggle switch. Attach one lead from the car radio and one lead from the transceiver, and use a common ground for both.

Don't turn the rig on yet!

Check your job of wiring. A little precaution now can save time and money. If you're sure everything is wired correctly, throw the switch.

Run tests at low power first and check

The advantages of a collapsible whip antenna are many. You may want to reinforce the whip to halt wild swaying when cornering by using an insulated brace mounted on the car body.



Special attention should be given mounting the power supply. Be sure plenty of air reaches it and make it as water tight as possible. Keep all cables as short as is practical.

the standing wave ratio by inserting an SWR bridge in the antenna line. An SWR of 2:1 is reasonable.

Now try full power, and have a friend listen to your signal, checking for clarity, strength and frequency drift (which could be caused by having too long a cable from the battery to the dc supply!)

That about does it. The pleasures of mobile operation await you.

With the current sun spot activity, world wide communications are possible using low power on 20 meters. If you like DX (who doesn't), now you can enjoy it while you take a Sunday drive, or while you're caught in a traffic jam on the freeway.

If you can't hear the weak DX stations because of the ignition noise, try one of the commercially made suppression kits.

I work the VK's and ZL's regularly from California with S9 plus signals and DXCC is about 50 countries away. You can enjoy mobiling, too, and share the adventure. But be sure you do a good job when you install the rig. It'll pay off. . . . WB6ACM

Getting Your Extra Class License

Part I — AC-DC Theory

Having completed the study course for the Advanced Class examinations, let's turn our attention to the Extra Class ticket and its technical requirements.

The official FCC study list to prepare for the Extra Class exam includes 79 questions, most of which appear much more forbidding than do the 51 for the Advanced Class license. However, if you've stuck with us this far you may be amazed at how much of the required information you already have!

We'll tackle the Extra Class just as we did the Advanced, by selecting several questions from the study list which deal with the same general subject, and then exploring that subject in detail. We'll also continue to paraphrase the official questions into broader queries, to assure that we get all the necessary information rather than just enough for memorization.

At times, we'll refer back to the Advanced Class articles; in several cases, our broader questions covered not only the data needed for Advanced tickets but that for Extra Class as well.

To kick off this course, let's take the group of questions dealing with ac and dc theory. We covered much of the information needed to answer these questions last time out, in the final installment of the Advanced Class course, and so this is a good time to get the rest of it.

The FCC study list questions included in this group are (all numbers, as always, are from the study list):

10. What is the meaning of the time constant in a resistance-capacitance circuit?
16. What are inductive and capacitive reactance? How are their phase angles related?
25. How do mica and paper dielectric bypass capacitors compare at different frequencies?
26. How do filter capacitors made of mica and paper compare at different frequencies?
30. What does the term "power factor" mean in reference to electric power circuits?

All of these questions deal with characteristics of capacitors and inductors—even number 30. Last time out we went into great detail concerning reactance, so we'll refer you back to that one so far as question 16 is concerned. The rest of the group can be covered by posing four questions:

First would come "How do capacitors and inductors work?" With that settled, we can ask "What are time constants?" to get a handle on question 10. While we find out how the devices work we'll meet the term "dielectric" and so a natural successor in our list of questions would be "What is a dielectric?" There, we'll find answers which apply to questions 25 and 26. Finally, we'll ask "How about power factor?", and dispose of the final question from the original list for this month.

Ready? Let's get on with it.

How Do Capacitors and Inductors Work? Both capacitors and inductors are, essentially, energy-storage devices. Each of them works by storing energy, but they do so in opposite ways.

Energy may be stored in many different ways. A living creature, for example, stores heat energy by chemical action which transforms the energy already stored in its food into another class of compounds more suitable for storage in its body. Both the food and the body itself are basically chemical structures—but the energy which is stored,

and which powers the creature, is that of heat.

Similarly, a storage battery or storage cell stores electrical energy by chemical action. The electrical energy causes chemical changes within the storage cell. These changes turn the electrolyte of the cell from its original chemical compound into another. When, sometime later, the electrical energy is needed, the second compound is transformed back into the first—and in the process, the electrical energy is made available to an external circuit.

The energy storage action of capacitors and inductors is somewhat more direct in that no chemical transformation occurs. The capacitor stores electric (sometimes called electrostatic to distinguish it from "electricity") energy by creating a temporary "electric field", while the inductor stores magnetic energy by forming a magnetic field. Since "electricity" always involves *both* electric and magnetic fields, storing either kind of energy in its own field is a direct storage of "electricity".

A capacitor consists simply of two conductors, of any sort at all, separated by an insulator known as the "dielectric" of the capacitor.

An inductor, on the other hand, consists of only one inductor, surrounded by its magnetic field.

You can see from these definitions that *any* wire carrying an electric current must be an inductor, and any two wires which are not connected to each other must form a capacitor. This is absolutely correct.

In fact, this "stray" capacitance and inductance which is present in every electrical circuit is one of the biggest problems the VHF or UHF worker must battle. The inductance of a 2-inch length of hookup wire is not very large; normally you can merely ignore it, but when the frequency gets high enough it may be *more* inductance than the design calls for. Similarly, the capacitance from one pin of a tube socket to an adjacent pin is usually less than ½ pF, which again is a very small value—but when the frequency is far enough up there, this may be more than the maximum allowable for a circuit.

In the rather unrealistic world of "pure" theory, though, we can *imagine* such things as perfect resistors which have no capacitance or inductance, perfect inductors with no capacitance, and the like. And even in the more realistic world we live in, most of the time we can consider all the capacitance in a circuit to be contained in those components called capacitors, and all the inductance to be in the inductors.

These "normal" capacitors usually have plates and dielectric made out of thin, rather flexible material, and rolled into a cylinder or similar shape to occupy the least space. We'll look at the physical details of the various types of capacitors in more detail when we examine the properties of the dielectric, a bit later in this session.

The "normal" inductor usually has its single conductor wound into a coil, so that the magnetic field tends to be concentrated in a single region. This permits the field to store more energy in the same space, than would be the case if the conductor were stretched out straight. Inductors for *rf* use frequently use nothing at all to strengthen the field, but you will often find ferrite slugs used as "cores" in the inductor. The same current can create a stronger field in the ferrite core than it can in air, thus increasing the inductance of the coil. Audio inductors almost invariably use either ferrite or soft iron cores.

Brass slugs are also used in *rf* coils; they serve a purpose opposite to that of the ferrite. Where the ferrite core increases inductance of the coil, the brass slug decreases it. Effectiveness of either type of core depends upon how much of the field is occupied by the core; this permits adjustment of inductance by moving the core in or out of the coil.

Capacitors and inductors store energy without regard to whether ac or dc is flowing in the circuit which contains them. However, their energy is "polarized"; that is, a capacitor charged with dc will retain the polarity of its charge. In an ac circuit, the polarity reverses every half-cycle, and as a result the capacitor discharges at every reversal and re-charges with opposite polarity. This effect is the cause of phase shift, which we went into in such detail last time.

Both capacitors and inductors store energy by converting it from a moving "wave" into a stationary "field"; just exactly *how* this is accomplished is still not known, but the theoretical boys are pretty well certain that it's somewhat similar to the stretching of a rubber band which converts energy of

motion—kinetic energy—into energy of tension—potential energy.

The capacitor works on voltage, and stores it in an electric field, while the inductor works on current and stores it in a magnetic field.

Either kind of field is unstable, once energy is stored there. The energy, like the stretch of the rubber band, is eager to get out. That's what makes the whole idea practical.

The energy-storage aspect of capacitors and inductors is most apparent in some of their non-radio, dc applications. For example, a photographer's strobe-light unit uses large capacitors to accumulate a high-voltage charge. This charge is measured in watt-seconds, and a typical strobe operates at 50 to 100 watt-seconds, with anywhere from 250 to 2500 volts. The charge accumulates over a period of several seconds; some units take as long as a minute to re-charge after each shot. This means very little power is necessary. The discharge, however, happens in a very few thousandths of a second, so that during that time you have the equivalent of a 50-kilowatt light.

Another example, using an inductor rather than a capacitor, is the Kettering auto ignition system, which was standard equipment on all autos from the days of the magneto until the rise of transistorized ignition and is still widely used. Here, the ignition points are closed most of the time and a current of several amperes flows through the ignition coil primary. This is a rather sizeable inductor, and a large magnetic field results which stores much energy. When the points open, the primary circuit is broken. The current no longer flows, which releases the "stretch" holding the field in place, and the magnetic field collapses. This collapse releases the stored energy of the field, which reappears as high-voltage pulses at both the primary and the secondary windings.

The purpose of the whole thing is to produce a 25000-volt pulse at the secondary winding; the 250 to 500-volt pulse in the primary circuit is an unwanted side effect. That's the purpose of the capacitor known to mechanics as "the condenser" across the points; it stores the energy of the primary pulse and returns it to the circuit.

These examples bring out one of the fundamental differences between energy storage in a magnetic field and in an electric field. A capacitor is charged by application of voltage, and the electric field will remain there—stretched—until you discharge it. The inductor is "charged" by applying current, but the magnetic field remains only as long as current flows and "snaps back" as soon as current stops.

What Are Time Constants? It would appear, from what we've seen so far, that any capacitor could store as much energy as any other capacitor. If you qualify this by adding to it the words "of the same capacitance", the statement is true. The only factor affecting the amount of energy which a capacitor can store is its capacitance, which is determined by the *area* of its conductors or "plates" and the thickness of its dielectric.

Practical capacitors, of course, have a few other limitations such as voltage rating and self-inductance, but we'll get into these later. The essential point at this stage is that the size of the field is limited only by physical characteristics of the capacitor itself and not by any other component in a circuit.

In most if not all applications of capacitors, though, we must consider not only the capacitor but also the rest of the circuit—and the other parts of the circuit *do* affect the size and strength of the field at any specific instant.

For instance, let's look at the capacitor as being something like a large water glass. It can hold a pint, let's say. We can fill it up from a gallon bucket in a hurry, or we can trickle water in from a dripping faucet. The glass will still fill to its pint capacity—but it will take longer.

A capacitor being charged with dc reacts in just the same way. If we connect it directly to a battery, it will charge rapidly until it reaches approximately the same voltage as the battery. If we connect it to the battery through a large resistor, which reduces the current flow to a mere trickle, it will take longer to charge—but it will eventually reach the same voltage, if we leave it connected long enough.

That's the whole meaning of the term "time constant". As it turns out, we can connect a 1-mfd capacitor in series with a 1-megohm resistor to a 12-volt battery, and the capacitor will have reached a voltage of about 8 volts after 1 second. If we connect a 2-mfd capacitor in series with that same 1-megohm resistor, it will take twice

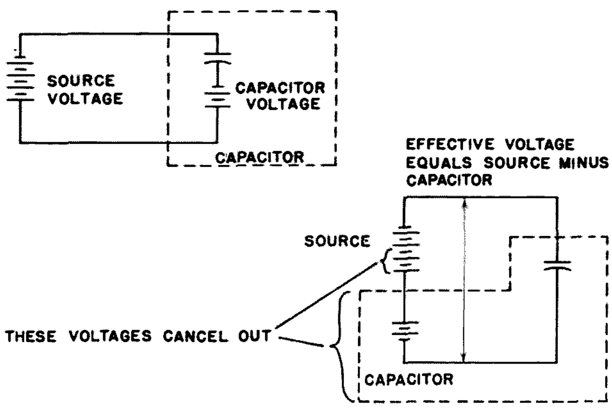


Fig. 1—When a capacitor is charging, three voltages must be considered. The obvious one is the voltage of the source from which the charge comes. However, as charge accumulates on the capacitor it takes on a voltage which acts to oppose the source voltage; the effective voltage available to keep charging action going is then the source, minus the voltage on the capacitor. This is why charging slows and eventually apparently stops when a capacitor is connected to DC.

as long to reach the same voltage since the capacitor is twice as large. However, if we use a 2-mfd capacitor and a ½-megohm resistor, the time will remain constant.

For capacitors, time constant is defined as the product of resistance in ohms times capacitance in farads. Resistance in megohms times capacitance in microfarads gives the same result, and the resulting time constant is measured in seconds. In our examples, 1 megohm x 1 microfarad = ½ megohm x 2 microfarads = 1 second time constant.

The same rules apply to inductors, but the R-L time constant is not nearly so widely used as is the R-C time constant. We'll concentrate on the R-C case.

You probably noticed that in our examples above the capacitor had charged only to about 8 volts, rather than to the full battery voltage, after 1 time constant's worth of time had elapsed. Why?

The reason is a little tricky, and most texts resort to differential calculus to explain it. Let's see if we can't make it clear by using only simple arithmetic.

When we set out to charge a capacitor, it may look as if there's only one voltage to worry about—but actually there are three. The *source* voltage (our 12-volt battery) is the obvious one. The hidden ones are the *capacitor* voltage and the *effective* voltage. The schematic in Fig. 1 shows what they are.

The capacitor voltage can be thought of as a battery inside the capacitor. Actually, it's the voltage of the charge which we have *already* stored, and since in the series circuit which the charging current must traverse it's opposing the source voltage, it makes the circuit act as if the source voltage were continually decreasing.

For instance, when we have the capacitor charged to 8 volts in our earlier examples, the capacitor voltage is 8 and the source voltage is steady at 12. So far as the capacitor alone (without regard to its already-existing charge) is concerned, the situation is the same as it would be if source voltage were (12 - 8) or 4, and capacitor voltage were zero.

This difference between source voltage and capacitor voltage is what we call "effective" voltage. It's the only voltage available to *add to* the existing charge.

When we started, capacitor voltage was zero and the effective voltage was the same as the source voltage, or 12. As soon as the capacitor had charged any at all, though, the resulting capacitor voltage opposing the source voltage began reducing the effective voltage.

When the capacitor reached 1 volt, the effective voltage was down to 11; when capacitor voltage reached 2, effective voltage was down to 10. By the time capacitor voltage was 8, effective voltage was only 4.

It's like an ant crawling up the side of a wall, who covers half the distance between where he is and the top in any given period of time. During the first period, he makes it half-way up. During the next, he gets half-way up the remaining half, or a total of ¾ of the way up from the start. In the next period, he gets half-way up the remaining quarter, or ⅞ of the total distance.

The higher he gets, the slower he goes. Also, you may notice, he will *never* make it to the top of the wall. No matter how high he gets, he can only make half of the remaining distance in the next period of time.

The same thing's true of a charging capacitor. No matter how long you charge it, it can never reach the full source voltage.

In practice, though, it will get so close—within a few million-billionths of a volt—that you can't tell the difference. And the

longer you leave it connected, the closer it will get.

Our R-C time constant, ohms times farads, is simply a convenient and easy-to-use measure of that "time period" in which our poor ant was climbing. There are good mathematical reasons why it works out this way, but for our purposes it's only necessary to know that a capacitor will charge to 63.2 percent of the source voltage during one time constant, and to know that the speed of its charge is always changing as the voltage changes.

Fig. 2 tabulates the three essential voltages at selected time periods between 0 and 10 time constants, for a capacitor being charged from a 100-volt source.

All this time, we've been talking about voltage only—but whenever we have voltage in action, we must have current too. What happens to the current in this circuit?

Initially, when the capacitor voltage is zero, the capacitor acts just like a short circuit so far as the power source is concerned. Theoretically, the current at this instant is infinite; in practice, it's limited only by the resistance of the wires in the circuit and the capability of the power source.

But as soon as the capacitor begins to charge, the capacitor voltage opposes the source voltage as we have seen and shown in Fig. 2, and so the current drops to a smaller value. The higher the capacitor voltage, the less current flows to charge it.

And as a matter of fact, you can use the figures listed in Fig. 2 to determine the current as well as the voltage at any time after charging begins. The same column of figures which shows "effective voltage" applies to current flow.

Initially at 0.0 time constants, the current flow will be 100 percent of that which the external circuit can provide. After 1/10 time constant, only 90.5 percent of the available current will be flowing, and after 10 time constants, current will have dropped to just 45/10000 percent of that available.

The time constant of an R-C circuit has many effects, not all of which are obvious. One of the more apparent is the possibility of using the effect to provide a means of timing events—and this provides the horizontal sweep timing signal for most oscilloscopes. Less apparent is its application to bypass and filtering action.

But in the circuit of **Fig. 3**, for example, if the input signal consists of pulsating dc such as you would get from a full-wave rectifier, and no current were being drawn from the output of the circuit, the capacitor would eventually charge to approximately the peak value of the input signal voltage. Having reached that peak, it would retain that voltage level because the time constant of the R-C network R1-C1 is so long that the capacitor voltage cannot change greatly in the time between the peaks of the input signal.

Time (Time Constants)	Voltages Source	Capacitor	Effective
0.0	100.00	0.0	100.00
0.1	100.00	9.5	90.5
0.2	100.00	18.1	81.9
0.3	100.00	25.9	74.1
0.4	100.00	33	67
0.5	100.00	39.3	60.7
0.6	100.00	45.1	54.9
0.7	100.00	50.3	49.7
0.8	100.00	55.1	44.9
0.9	100.00	59.3	40.7
1.0	100.00	63.2	36.8
1.5	100.00	77.7	22.3
2.0	100.00	86.5	13.5
3.0	100.00	95.02	4.98
4.0	100.00	98.17	1.83
5.0	100.00	99.326	0.674
6.0	100.00	99.752	0.248
10.0	100.00	99.9955	0.0045

Fig. 2—This shows how effective voltage goes down while capacitor voltage goes up. After 5 time constants, capacitor is so close to full charge that it can be considered "charged", but charging continues indefinitely. You can use this for any source voltage by reading the voltage values as being "percent of source voltage".

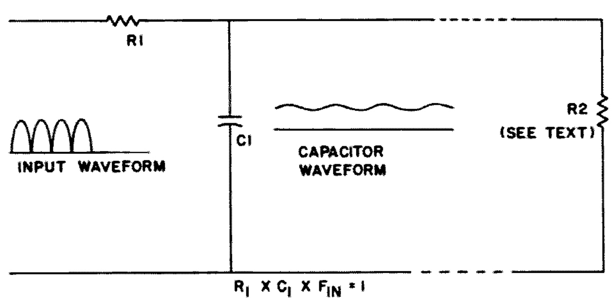

Fig. 3—Time constant of a resistance-capacitance circuit can be used to filter out low-frequency signals, by proper choice of time constant with respect to input frequency and output loading. See text for discussion of resistor R_2 which represents load on the filter and affects actual resistance and capacitance values for any practical circuit.

If the value of R1 is reduced, shortening the time constant, the output signal level would have time to fall back in an attempt to follow the input signal. If R1 were reduced to zero, the output signal might be able to follow the input signal almost exactly and no filtering action would occur.

When a load is applied to the circuit, it acts just as if resistor R2 were connected (unless the load is itself an inductor or a capacitor, and we're not considering that kind of load at this point). Now the charge on Cl is bled off through R2 during the time between peaks, and the output level may tend to follow the input signal.

Increasing CI or Rl, either one, will lengthen the time constant and keep the output level more constant. If Rl is increased, though, less current may be taken from the output; if the time constant is lengthened by increasing CI, the available current will not be reduced.

The exact relationship between time constant of a filter or bypass circuit such as that shown in Fig. 3. and the lowest frequency at which bypass or filtering action is effective, is complicated greatly by the variables always present in practice. These variables include the waveform of the signal to be bypassed or filtered, the current through Rl and that through R2, and a number of other quantities.

A useful rule of thumb, however, is to always make the time constant at least equal to one full cycle of the lowest frequency to be filtered or bypassed. For a low-frequency cutoff of 100 Hz, for instance, the time constant should be at least 1⁄100 second. This would work out to be a 0.1 mfd capacitor for CI and a 100 K resistor at Rl, or a 10-mfd capacitor at CI and a IK resistor at Rl, or possibly a 100-mfd capacitor and a 100-ohm resistor. All three of these combinations provide a 0.01-second time constant and would have equal filtering action; the choice between them would depend upon power requirements and impedance of the circuit being filtered.

What Is A Dielectric? We noted several pages back that a capacitor consists of two conductors, known as "plates", and an insulator separating them, called a "dielectric". This implies that any and all insulators are "dielectrics", and in fact this is true. However, when an insulating material is used primarily as the dielectric of a capacitor several characteristics of the material assume considerable importance. They not only help determine the capacitance of the resulting capacitor, but its useful frequency range of operation, the voltage levels at which it may be used, and the temperatures at which it may be employed.

To help us see just how the characteristics of the dielectric determine all these properties of the capacitor, let's take a rather oversimplified look at the way in which a capacitor stores energy.

All materials, of course, are composed of atoms, and atoms, in turn, are composed of protons, neutrons, and electrons. Only the electrons concern us in this view.

The major difference between an insulator and a conductor is in the way in which the electrons are held to the atoms which compose the material. In a conductor, many of the electrons are "free"—that is, they are able to migrate from one atom to another. Since each electron is a minute negative electric charge, this migration or "drift" of the free electrons is what we generally call an "electric current" in the conductor. The greater the pressure, or voltage, which we apply to the material, the more electrons move—and the larger the current.

In an insulator, on the other hand, the electrons are "bound" to their parent atoms more firmly and are not free to drift. While they can, and do, travel comparatively long distances from their "home positions", the binding forces remain to pull them back into place once any pressure is removed. It's very much as if they were attached to the atoms by rubber bands of various thicknesses.

When we apply a voltage to the conducting plates of a capacitor, the pressure from the voltage source pushes a large number of free electrons onto the negative plate. Since charges of like polarity repel each other, the combined negative charge of all these free electrons pushes the neighboring "bound" electrons in the insulating dielectric away from the negative plate.

The push away provided by the repulsion force is opposed by the binding forces within the dielectric, but in all cases the repulsion force is the strongest and it overcomes the binding forces.

As a result, the electrons of the dielectric, although still bound to their original positions, are pushed out of place and pile up near the positive plate. There, they repel the free electrons in the conducting positive plate, which in turn drift on out of the capacitor into the remainder of the circuit.

The total effect is that a current flows "through" the capacitor—but in so doing,

the binding forces within the dielectric have been stretched to permit the current to flow through.

This tension of the binding forces is usually called "stress",, and *is* the stored energy. So long as the binding forces remain stretched, the energy remains stored within the capacitor. It would be just as accurate to say that so long as the capacitor retains its charge, the binding forces remain stretched.

When a discharge path is provided from one plate to the other, then the binding forces within the dielectric pull the bound electrons back into place. This creates a shortage of electrons at the positive plate and an excess of electrons at the negative plate—but the excess electrons flow through the external discharge path back to the positive plate to make up the deficit there. In the precess, their energy is released as electric energy.

As we said, this is an oversimplified view of the process and makes no mention of the "electric field" associated with a capacitor. The oversimplifications lie in the area of "What keeps the binding forces stretched out?", and any attempt to answer *that* one accurately would lead us far into the depths of solid-state physics and beyond the scope of this study course.

But it may be a bit clearer now just how the physical and atomic characteristics of a dielectric can determine so many of the properties of the complete capacitor, since the dielectric is the place in which the actual energy storage occurs.

For instance, some materials have stronger binding forces than others. The stronger the binding force, the more pressure will be required to put in the same amount of "stretch" or stress. This means that the material with the stronger binding force must require a larger electric charge, if physical sizes are the same, than one with a weaker binding force. Its capacitance, then, must be smaller.

This characteristic is normally called the "dielectric constant" of the dielectric, and is also a measure of its insulating capabilities. The dielectric constant is a number which provides a comparison of the dielectric in question with clean, dry air. That is, air has a dielectric constant of 1. Any material whose dielectric constant is greater than 1 will permit greater capacitance for the same thickness than will air. For instance, a material with a dielectric constant of 2 will make a capacitor having twice the capacitance of one with air as a dielectric, all other things remaining equal, and another material whose dielectric constant is 10 will provide 10 times as much capacitance as air or 5 times as much as the first material.

While the binding force can be stretched over a considerable distance, it cannot be stretched indefinitely. Like a rubber band, it eventually reaches a point at which it snaps. The dielectric material is then permanently damaged. This effect is measured by a characteristic called "dielectric strength", which is usually rated in volts-per-mil. The volts-per-mil is the voltage necessary to cause permanent breakdown in a 1/1000-inch-thick sample of the dielectric.

Very few, if any materials, are either perfect conductors or perfect insulators. The most perfect insulators known still retain a few free electrons and so can act as partial conductors, while the most perfect conductors (at normal temperatures) still retain some resistance. This provides a third factor in the dielectric which affects the capacitor greatly—one called "volume resistivity" and measured in ohms per cubic centimeter. The higher the resistivity, the better the insulating qualities of the dielectric. Surprisingly, some popular dielectrics have rather poor insulating qualities; it all depends upon the particular application!

The fourth major characteristic of the dielectric which has large effect upon the properties of the capacitor is the "dissipation factor". Like everything else, the stretch-and-release action of the dielectric is far from perfect. Not all the energy stored when the binding forces are stretched is turned back when the stress is released. Some of it is dissipated as heat within the dielectric.

The "dissipation factor" is the ratio of energy released to energy lost, and like dielectric constant is measured by comparison to air. Air has a dissipation factor of 0.0; most if not all other dielectrics have higher factors. In most, it is also frequently sensitive, with losses increasing as the signal frequency goes up. This is the principal reason why some types of capacitors are suitable only for use at dc or audio frequencies, while others work well up into the UHF spectrum.

A perfect dielectric for an all-purpose capa-

citor, then, should have a high dielectric constant to keep the capacitor small; very high dielectric strength to permit its use with high voltages; high volume resistivity to prevent loss of the stored energy by internal leakage; and a low dissipation factor so that most of the stored energy will be returned to the external circuit upon demand.

Few dielectrics meet all these requirements—and that's why we have so many different types of capacitors available. Of all the various insulating substances available for use as dielectrics, only six major types have found wide use, with a seventh (not usually considered to be an insulator) coming into popularity for special applications.

The classic dielectric is, of course, air. Its dielectric constant is so low, however, that air capacitors of practical physical sizes are limited to small values of capacitance.

A substance even better than air as a dielectric in most of the critical factors is ruby mica. Again, though, the dielectric constant is relatively low and so mica capacitors of any appreciable capacitance are extremely large.

The most popular dielectric for general purpose use through the years has been paper. The paper is almost always treated with special materials to modify the critical factors, but dielectric constant is always high. The principal problem with paper as a dielectric is threefold—the dissipation factor, while reasonable at low frequencies, becomes excessively high in the *rf* region; the dielectric strength is not always great enough to get adequate capacitance and voltage ratings at the same time; and the physical construction, being so much like a coil, introduces undesirable self-inductance.

Despite these limitations, paper capacitors are still the most widely used in moderate capacitance ratings for dc, audio, and low-frequency *rf* applications—and their only serious rivals are members of another very similar class.

These rivals are the plastic capacitors, which use any of a number of types of plastic as the dielectric. The qualities of the plastic can almost be tailored to the needs of the capacitor designer, permitting near-perfect capacitors for any specific purpose, but the physical limitations remain.

Similar to plastic capacitors in some ways, and vastly different in others, are the capacitors which use ceramic dielectrics. Most of us tend to think of ceramic capacitors as relatively recent devices. Yet glass is a ceramic material—and the very first capacitors, the venerable Leyden jars which date from before the invention of the electric battery, used glass as their dielectrics.

Like plastics, ceramics can be made with almost any characteristics. "Ceramic" capacitors fall into two broad classes, though. One of these—which includes glass—is similar in most ways to mica. It offers extreme precision of manufacture, excellent stability of characteristics over wide temperature ranges and humidity conditions, and moderate values of dielectric constant. The other is not so stable, but has the highest dielectric constant of any type of insulator in wide use except one. This type of ceramic is used in the popular disk bypass capacitors and other units which feature high capacitance in small size. Unfortunately, its resistivity and dissipation factor prevents its use in general applications and limits it to bypassing and filtering.

The sixth type of dielectric provides the highest dielectric constants of all, but at the cost of having the lowest dielectric strength and resistivity, together with polarization effects which restrict its use to dc circuits. This is the electrolyte dielectric, used in electrolytic capacitors.

An electrolyte dielectric is a chemical solution which, in the presence of voltage stress, produces an ultra-thin oxide coating on one face of one plate of the capacitor. This oxide coating is the actual dielectric, and the electrolyte actually serves as the other plate of the unit.

When an electrolytic capacitor is manufactured, its dielectric is "formed" by operating it for a specified time at specified voltages. The unit should never be used at higher voltages than it is rated for—and likewise should not be allowed to stand idle for excessive periods of time, or the oxide coating may go back into solution and cause failure of the unit when voltage is applied.

Because of its unique characteristics, the electrolyte dielectric is used mainly for filter capacitors where the need is for largest possible capacitance values with moderate physical size, and comparatively large amounts of leakage can be tolerated.

Material	Dielectric Constant (relative)		Dielectric Strength (Volt/mil)	Volume Resistivity (ohm/cm³)	Dissipation Factor (relative)	
Frequency	60Hz	1 MHz			60Hz	1 MHz
AIR	1	1	1200	very high	0	0

Tantal	140	——	150 V max	very low		very high

Fig. 4—Key characteristics of the various types of dielectric materials are listed above. Note that all have comparatively high resistivity and most have small dissipation factors.

Fig. 4 lists the four key characteristics for the six types of dielectrics we've examined so far. The figures come from the fourth edition of "Reference Data for Radio Engineers", but in most cases have been modified to cover an entire range of materials rather than specific dielectrics. (The plastics entry, for instance, condenses two pages of reference data into a single line covering the entire range.)

In general, the dielectrics with the larger dielectric constants are used more frequently at dc and low frequencies where larger capacitance values are more frequently needed. The critical factor so far as frequency is concerned is that of dissipation—this is a measure of internal losses, and dielectrics with excessive internal losses are not usable at higher frequencies.

For bypassing, for instance, either a paper or a mica capacitor can be used at low frequencies, but paper would be the more normal choice because of its higher dielectric constant. A physically smaller capacitor could be used, if paper were chosen. As frequency goes up, though, losses in paper increase more rapidly than do losses in mica—and at the same time the capacitance values required for effective bypassing go down. This makes the dielectric constant less important, and the preference would switch to mica somewhere in the neighborhood of 1 MHz.

The high-capacitance ceramic units, however, would be preferable to either so long as capacitance values of 0.1 mfd or less would suffice, since the unit would be smaller than an equivalent-capacitance paper unit, and would perform at least as well as mica up through the UHF spectrum!

In a tuned filter, on the other hand, the mica unit would be preferable in all cases. In a filter, the self-inductance of the capacitor would become an important factor, and that of a typical paper unit would vary widely from manufacturer to manufacturer because of differing construction techniques. All mica capacitors, however, are made in the same layer-cake fashion because mica is brittle, and so the variations would be held to a minimum.

How About Power Factor? Quite a ways back there, in looking at the low-pass R-C filter circuit of Fig. 3, we said that a load on this circuit would look like a resistor, unless the load had either inductance or capacitance—and we begged that question at the time. It's time for it now.

Obviously, any electric circuit could be put into a solid black box with nothing exposed except the terminals, and it would be rather difficult to tell what was inside.

When we're looking at the power circuitry of any device, we can forget all about the signal terminals and look only at the power terminals on that black box. Most of the time, we'll find that the innards of the box cannot be distinguished from a large resistor.

That is, if the gadget operates on dc, it takes both voltage and current, and replacing the black box with a resistor which draws the same current at the same voltage would put the same load on the power supply.

Sometimes, though, that resistor representing the circuit's power usage might appear to have a capacitor in parallel with it—or an inductor in series. If it draws heavy current when it's first connected, which comes down as time passes, that's the same action we would expect from a capacitor. On the other hand, if it draws less current at first than it does after it's been connected for a while, that's the action an inductor would produce. In the first case, we would call it a capacitive load, and in the second, an inductive load.

On a dc circuit, the inductance or capaci-

tance of the power loads is of little importance except at the instant of switching power on. When the power circuit uses ac, though, the inductance or capacitance appearing at the power terminals of a device can wreak havoc with other gadgets on the same line, because of the phase shift introduced on the main power lines by these reactances.

That's what "power factor" amounts to; it's just another way of measuring the apparent capacitance or inductance of a load on an ac power line. Any normal resistive load has a power factor of 0. This means that it is effectively a pure resistance to the power line, free of either inductance or capacitance.

A completely reactive load, having no real resistance in it but composed exclusively of either inductance or capacitance, would have a power factor of 1.0. If it were capacitive, it would be a *leading* power factor, and if it were inductive, the power factor would be said to be *lagging*.

In other words, the term "power factor" refers to the percentage of reactance in the load. The whole thing is almost identical to the "Q" factor we normally apply to coils and tuned circuits, but power engineers use the "power factor" approach instead.

Many "normal" devices used on ac lines have some reactance in them, which reflects to the power line as a power factor. Among these are electric motors, which reflect large inductive power factors when they are coasting, and are highly capacitive loads when power is first applied. The capacitive nature of the motor's load on the line is the reason most motor circuits use slow-blow fuses; these fuses will carry the "charging current" required by the reactive load without blowing, yet still provide protection if the current drain continues for an excessive length of time.

Transformers may reflect either inductive, resistive, or capacitive loads, depending upon the type of circuit connected to the secondary.

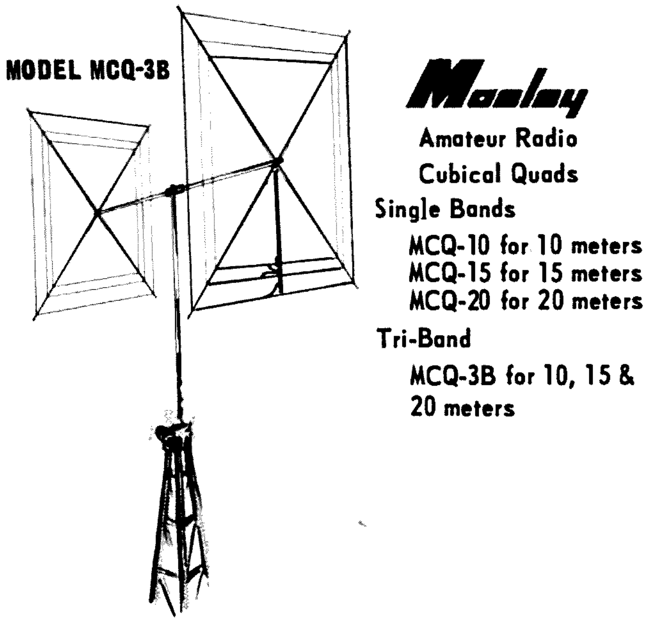
In general, power factors of any type of load can be corrected to the ideal 0.0 figure by deliberately introducing the opposite kind of reactance to cancel out that present in the load itself. For instance, "synchro motors" (commonly known as selsyms although this term is actually a trademark) usually appear to be inductive loads to their power sources. Correcting capacitors are connected across the lines supplying primary power to these devices, to "tune out" the power factor and keep the main power line itself at a power factor of 0. The amount of capacitance required to do this depends upon the power factor present in the load, which in turn depends upon the number of devices and their exact operation conditions.

In most ham power wiring, it's safe to assume that the power factor is always zero and not attempt to adjust it. Normal household wiring is quite tolerant of reactance, as are most devices used with it.

The term "power factor" is also used, in somewhat different surroundings, to describe the "dissipation factor" of a capacitor which we examined in the previous question. This usage, however, is not in reference to electric power circuits. When applied to a capacitor, the power factor is similar to the dissipation factor, and indicates the amount of loss to be expected within the capacitor at power-line frequencies. The higher the power factor, the greater the internal losses.

Next Session. The Extra Class exam is more loaded with theory than is any other amateur examination. While we're working with the basics and some of their finer points, let's stay with them a while longer and examine the details of amplifier operation. Even if you're not interested in the higher ticket, you may find it nice to know how an amplifier works! ■

NEW PRODUCTS



Mosley Amateur Radio Cubical Quads

Mosley's newly released MCQ Cubical Quad Antennas are available in single-band form for 10, 15, or 20 meters, or as a tri-band quad for all three bands. The antennas feature Mosley's rugged boom-to-mast mounting assembly with stainless steel clamps, 52 ohm coax feed to wire elements, and a Gamma Match coupling arrangement that maintains an SWR of 2.2:1 or better across the entire amateur band. Shipped with boom, spreaders, wire, hardware and instructions. For further data write to Mosley Electronics Inc.. 4610 N. Lindberg Blvd., Bridgeton, Missouri 63042.

TAB Book Catalog

If you're in ham radio as a game, or one of the electronics fields for life and advancement, there is a TAB book that you will be interested in. A recently published catalog describes over 100 current and forthcoming books, dealing with broadcasting, servicing, basic technology, electric motors, audio and hi-fi, test gear, transistors, and several other subjects. The catalog is available free upon request, from TAB BOOKS, Blue Ridge Summit, Pa. Ask for their 1968 catalog.

VHF Converter

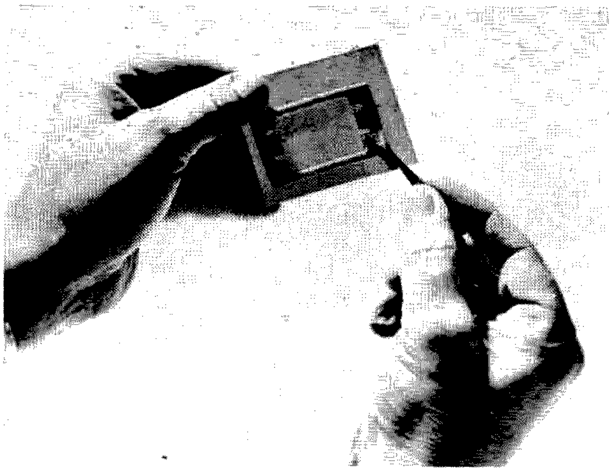
The performance of 1957's elaborate vacuum-tube receiving converters is considerably improved upon by today's inexpensive solid-state models. Prices are lower, too. For instance, here is a 432 MHz to 14 MHz converter, typical noise figure of 3.6 db., at a kit price of $29.95. Hams who have been around for a while will realize how remarkable this really is. The circuit requires about 4.5 mA from a 9 to 12 volt battery. Kit available from VHF Associates, PO Box 22135, Denver, Colorado 80222. Since they are an active company, you might ask for their catalog, too.

Varactor Multiplier

Sometimes it is easier to generate radio frequency power at a relatively low frequency, and then to use a simple circuit to generate a much higher frequency output. This possibility is a relatively new arrival in amateur electronics, using a key component now known as a varactor diode.

Varactor diode circuits can handle considerable amounts of power. For example, here is a varactor multiplier that will take up to 40 watts input on 144 MHz to generate about 24 watts output at 432 MHz. Unlike ordinary multipliers, varactors will take AM or sideband inputs as well as CW, without generating unacceptable distortion of the signal.

Several models are available. The one shown here, is priced at $54.95, from VHF Associates, PO Box 22135, Denver, Colorado 80222.

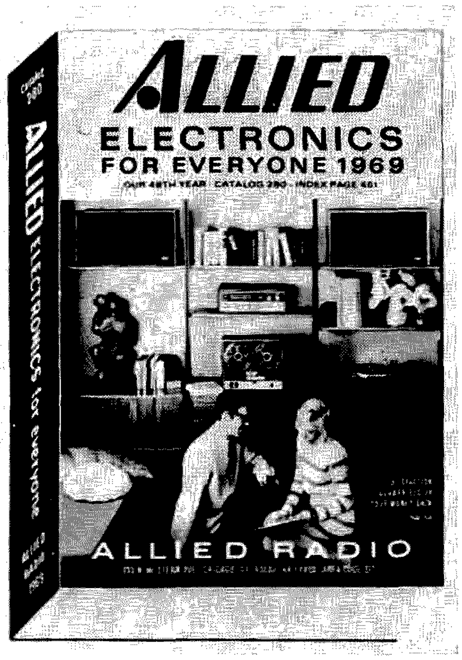


Metex Polastrip

If you are facing shielding or TVI problems, some modern ideas for interference shielding materials may interest you. For instance, how about POLASTRIP, a material provided with tiny wires in elastomer? Under pressure, the wires bite through dirt and oxides to complete connections between two parallel metal surfaces. If the POLASTRIP will not stay in place, you can ask for some POLASTICK. This is a special adhesive which will not interfere with the electrical properties of the strip material. For further information write to the Sales Manager, Metex Corporation, 970 New Durham Road, Edison, N.J. 08817.

Noise Suppressors

Mobile ham radio sounds like a lot of fun, but there are some hard technical problems to get over first. The car builders don't expect their buyers to have ears for electrical noise, but it turns out good ham radios are very sensitive, and respond strongly indeed to the electrical noises cars generate. Very often you can tell, without any technical knowledge at all, that your car is generating excessive noise, by hearing the noise change with the road or engine speed. Is there something you can find that will help stop this noise? Yes, and the Estes Engineering Co. is very active in this field. For a minimum job try their Ignition Suppression Kit #6415 at $8.95. Or for a more complete treatment their Universal Suppression Kit goes for $14.95 to reduce noise from spark plugs, distributor, generator, and other parts of the car. From Estes Engineering Co., 543 West 184 St., Gardena, Calif. 90247.



Allied 1969 Catalog

Allied Radio, perhaps the nation's largest consumer electronics distributor, has just published their #280 Electronics-for-Everyone, with 536 pages. This is a very large catalog, full of hi-fi gear, TV cameras and monitors, radios, phonographs and turntables, right through to test instruments, electronics components, and a line of kits. This line includes Allied's recently introduced KG-2100 Triggered Sweep Scope kit, and a variety of other test instruments. For all these details, the catalog is free on request from Allied Radio Corporation, PO Box 4398, Chicago, Ill. 60680.

Model 830 Transistor Commander

Weight: 3 lbs. Portable. Luggage type case is 9¼" x 6¾" x 6⅜". That's Amphenol's new service oriented transistor tester. It can also check diodes, zeners, and circuit supply voltages up to 100 volts.

Provided with color-coded meter scales for simplified tests, the Model 830 tester will measure the DC beta of small-signal or power transistors without their removal from the circuit. Out-of-circuit tests include I_{CBO} measurement. The tester is protected against accidental burn-out of transistors and diodes, or of the instrument itself.

Available from Amphenol Distributor Division, 2875 South 25th Ave., Broadview, Ill. 60153. Price, $79.95 net.

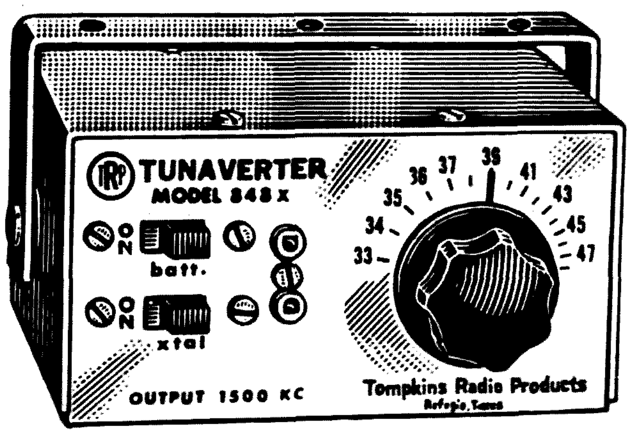
Semiconductor Handbook

Semiconductor Handbook, by Robert Tomer. From Howard B. Sams & Co. Inc., 1968

The good old days of small transistor handbooks are long past, but a coverage of the general principles along with illustrative applications can still be packed nicely between two covers that are not too far apart.

It takes 13 chapters and three appendices to do the job, but the field is covered from basic physics ideas through circuit fundamentals, component ratings, industrial and power applications, communications applications, advanced devices in general, FET's in some detail, and at last about 20 pages on micro-circuits and integrated circuits.

The coverage is improved by many small diagrams, located at frequent intervals through the text where they are handy to the appropriate paragraphs. This is a second edition, written by an experienced field engineer. His experience shows in the close relevance of the writing to readers' requirements. From Howard B. Sams & Co., Inc., $5.75.



RF Converter

Tompkins Radio Products has developed new models versatile *rf* converter line. Their new TUNAVERTER X line can tune over a range of frequencies, and then monitor drift free with crystal control by simply flipping a switch. Another channel may be monitored by changing crystals. Priced at $32.95 each less crystal from Tompkins' marketing division, Herbert Salch & Co., Woodsboro 73M, Texas 78393.

Dictionary of Electronic Terms

If you have not been working in electronics for very long, or if you have, for that matter, sometimes you need to find out what some new term means. A remarkably complete collection of old and new terms has just appeared on the market.

Allied's dictionary supplies definitions of power line, coil form, Citizens' Band radio, radio receiver, etc., which will be very useful to the beginner who wants to understand what the basics are all about.

But like any complete dictionary, it also meets requirements for the advanced worker. For instance, what is a ferrospinel? Triad? (a color TV term) or how about gamma ferric oxide?

The print in this 112-page dictionary is a bit small, but it is a good visible type face, offering a lot of material between two low-priced covers. A really complete book, and the definitions are not too short to be useful. From Allied Radio Corporation, Chicago, Ill., and the price is a remarkable one dollar.

Application Notes Catalog

If you're thinking about that next project, or the one following, maybe you can find some ideas in Motorola's new Application Notes Catalog. It is industrially oriented, but many of the entries should be interesting to non-engineers and amateurs. There are 130 entries, each describing the design and application of a circuit (or circuits), using Motorola components. A Selector Guide section at the beginning of the catalog lists the entries by applications categories.

Titles include "20 Watts at 1 GHz with Step Recovery Varactors," "An Integrated Circuit RF-IF Amplifier," "Using Shift Registers as Pulse Delay Networks," and "Unijunction Transistor Timers and Oscillators." Several reference guides, two catalogs, and the Semiconductor Data Book are also listed, in the back of the catalog.

For your copy of this handy guide, the Motorola Application Note Catalog, write Department TIC, Motorola Semiconductor Products Inc., Box 20924, Phoenix, Arizona 85036.

SUBSCRIBERS

We want to make absolutely sure that no one is using our 73 mailing list. We do not rent this list out as do other magazines. If your address label from 73 is distinctive and you find that you are getting any mail addressed in the same distinctive way please let us know immediately and send us the envelope or wrapper that you received so we can take appropriate action. Your help in this will be very much appreciated.

Is it Cold Down There?

A common query when the men on the "ice" at McMurdo Station in the Antarctic receive phone patch calls from home. Invariably the answer is "It's always cold and the temperatures are below zero in summer or winter."

Phone patching and teletype traffic to the Antarctic stations is a *must* every day of the year, band conditions permitting. The morale of the men depends on the communication link with their loved ones. The isolation in this remote part of the world is easier to take knowing there are dedicated radio amateurs ready at all times to serve them.

In former years the phone patching and traffic handling was done by any stations that would oblige in meeting schedules with KC4USV, McMurdo Station. However on May 11th, 1967 a new Navy MARS net began operations and now has a membership of thirty-seven stations that represent coverage of every part of the United States. Appropriately the net control station at McMurdo was assigned the Navy MARS call NØICE.

Operator at NØICE/KC4USV at McMurdo Station running a phone patch through the Navy MARS Antarctic Network. Official Navy photograph.

With the transition to Navy MARS, the Antarctic Network has become more effective in the handling of phone patches and teletype messages. In the first year of operation, the net handled 3,536 phone patches and 287 messages from McMurdo. Since April of this year, 2,433 phone patches and 2,503 messages have been completed and by the end of this year these figures will far exceed the totals of last year. During the winter over period (March to September) most of the teletype messages are of one hundred word personal letter text as mail service is non-existent during the Antarctic winter season. Also phone patches are not limited to five minutes due to the isolation of the men and the net is tailored for their welfare.

Operations on the net begin each night on the east coast at approximately 0100 GMT, the midwest at 0300 and the west coast at 0430 GMT on the Navy MARS frequency of 13,975.5 MHz. To expedite the handling of phone patch calls, numbers are assigned to the families of the men stationed at McMurdo. Each net member has a copy of these numbers with the name of the party to call, town or city and phone number. The net control need only pass the number to the net station for the phone patch call. At times there may be as many as ten to fifteen calls placed with some of the net stations to complete in his or her area.

In the summer season, September to February, the population increases at McMurdo Station with the arrival of the scientists and more military men. During this period, traffic to the states is at it's peak and sometimes it is necessary for the net to work around the clock, especially on Christmas and Mother's Day. Usually the net control station at McMurdo has several operators working in shifts and the net stations frequently have extra operators to man their stations. With McMurdo Station as the communications center for the outpost stations (South Pole, Byrd, Palmer and Plateau) this also adds to the traffic load.

The members of the Navy MARS Antarctic Net not only handle the phone patches and messages but in many cases shop for gifts

at Christmas, weddings, anniversaries and birthdays for the men in the Antarctic and have them delivered to their families. Such service by the net members are not forgotten and when the men return to the United States they make personal visits to these members to thank them for this service.

Recently during the operations of Project Facsimile Antarctic[1] the net was used as the liaison frequency between McMurdo and southern California. This was arranged for by Chief Navy MARS and assistance was given by MARS Director, Lloyd Madison of the 11th Naval District and MARS Director Terry Swartz who succeeded him. The net manager, Kenneth Nokes, NØRYE, arranged the operations schedules with the facsimile operators at McMurdo Station and thru the several months of the facsimile project did help to keep things operating smoothly on the net while transmissions of pictures were beamed to McMurdo.

Words of praise are offered to the net members of the Navy MARS Antarctic Net for their continued efforts to keep up the morale of our servicemen who do duty in remote parts of our world. The net roster lists the following stations associated with the Antarctic Net: NØAAJ, NØAJN, NØAOO, NØAYT, NØEJH, NØEQH, NØEQZ, NØEYX, NØFMO, NØFPG, NØFQP, NØFXQ, NØHFO, NØIDH, NØIFH, NØILN, NØIMK, NØITS, NØJBF, NØJRT, NØJVG, NØKMR, NØKWS, NØRLX, NØRTR, NØRUH, NØRWL, NØRYE, NØUSM, NØVAE, NØVQJ, NØWCK, NØWNN, NØXRO, NØYNK, NØYQJ, NØZFF, NØZHP, NAV 8 and NAV 11.

The contribution and dedication of these Navy MARS members can be expressed by the following letter addressed to the net manager, Kenneth Nokes, NØRYE, from Chief Navy MARS, LCDR. Robert E. Mickley:

"I would like to take this opportunity to express my appreciation to you and your fellow Navy MARS Antarctic Network members regarding the accomplishments of your operations during the wintering-over period.

Through you untiring efforts and those of your associates, you have succeeded in breaching the communication gap between personnel serving their country in the bleak Antarctic wastelands and their families and friends in the United States.

The record messages, radiotelephone calls and radio-teletypewriter letters handled by the Navy MARS Antarctic Network provided an outstanding service and exhibited a high degree of communication readiness. This accomplishment has brought significant acclaim to yourselves as individuals and to Navy MARS specialty operations.

Please express my appreciation to the members of network for a task "Well Done."

. . . K6GKX.

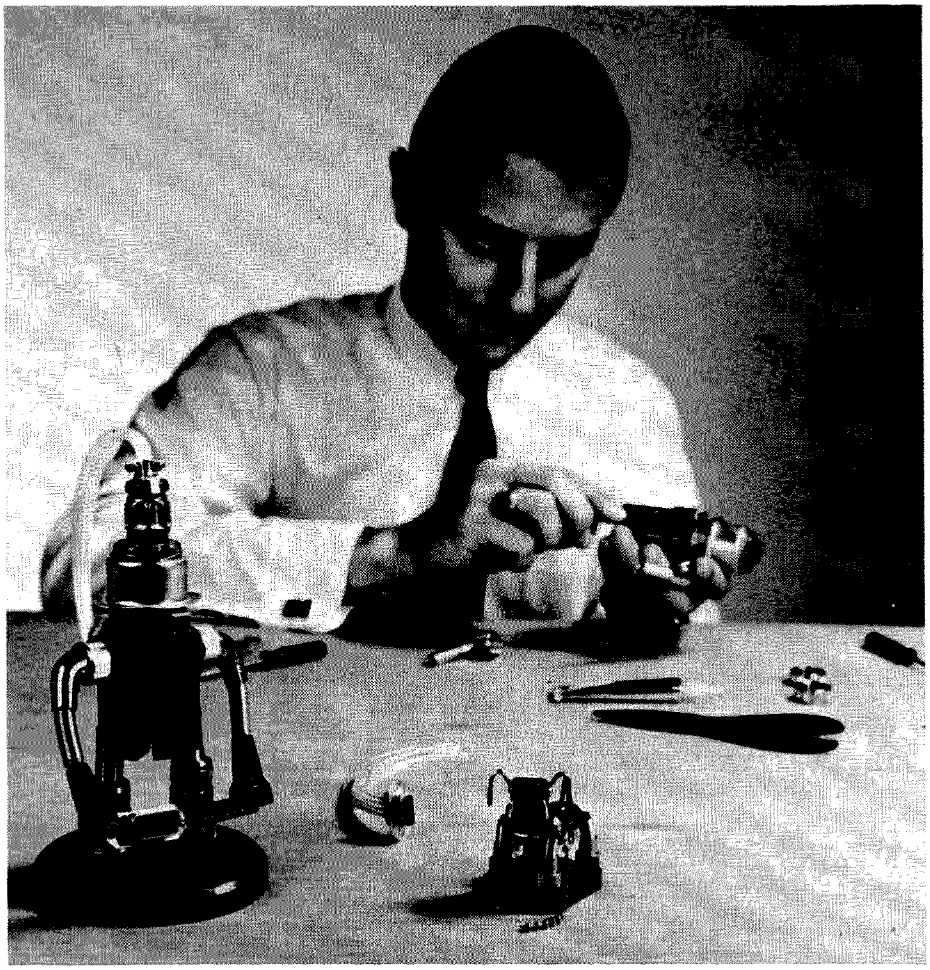
Creative Interconnections: the "Ampheham"



John Gove, product specialist for Amphenol Industrial Division of The Bunker-Ramo Corporation, Chicago, is shown above constructing a new "Ampheham," which, when completed, will look identical to the five-inch-high mechanical ham shown in lower left-hand corner. The Ampheham is constructed almost entirely of those types of microphone connectors, power connectors and tube sockets found in most hamshacks, manufactured by the division. The "amateur's" body, only exception to this rule, consists of a high-wattage prejector lamp socket, also made by Amphenol. A close look at the photograph also reveals John's "Amphepup" (foreground), a tiny dog fashioned from miniature-type Amphenol microphone connectors and tube sockets.

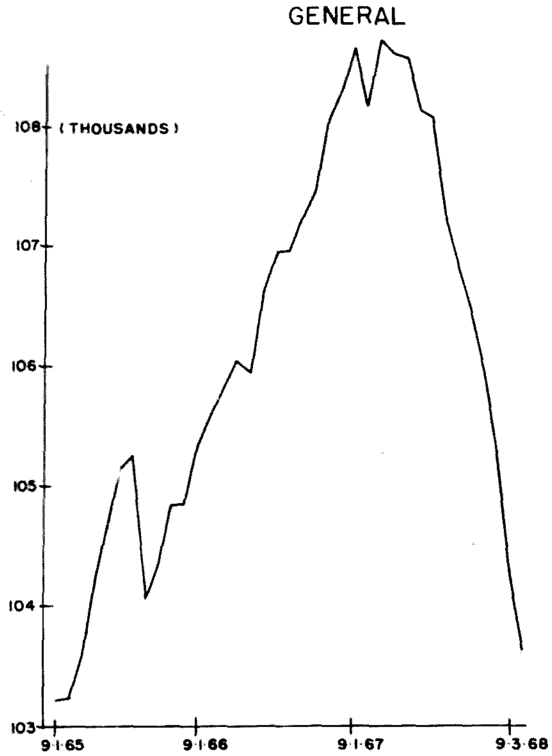
Incidentally, John's craftsmanship can also be seen on our December cover (the Amphepup and colorful, specially-designed "Ampheclaus"). ■

(...de W2NSD/1, continued from page 4)
mercial" to many amateurs. The widely reported failures at passing the Extra exam (possibly around 50%) also have tended to discourage fellows from taking the time and expense of trying for it.

Up until 1968 the Advanced Class license was closed to newcomers and we see the gradual drop off in licensees as cigarette cancer and apathy ate into the ranks. It was dropping off about 1000 a year or so. Then, when the license was opened again last year, in trooped the troops. About 5000 new Advanced Class licenses were issued.

Considering that the most choice twenty-meter phone frequencies are now restricted to Advanced and Extra Class licensees, the number of new licenses is piddling.

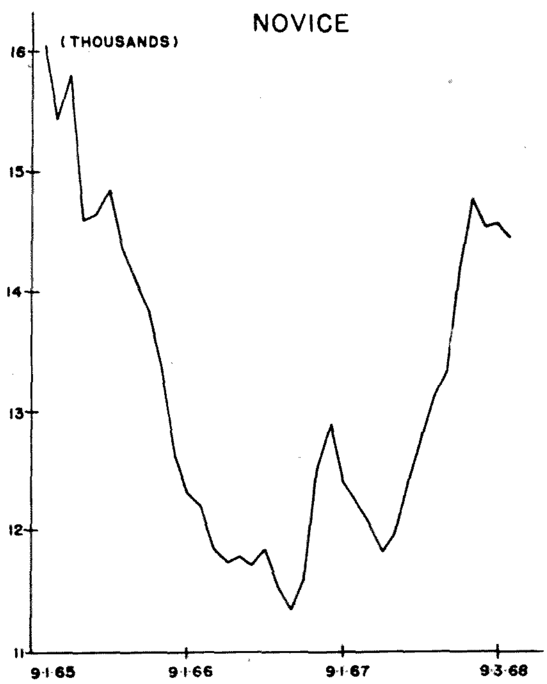
Most of the new Advanced and Extra came up from the General Class license, as we can



see from the graph. There is a loss there of about 5000, pretty much the same number that turned up in the Advanced category. 5000 out of 108,000 Generals is not exactly a tumult. It is more like a 4.6% response. Less than one in twenty! Perhaps this helps to explain the enormous vacuums in the new Extra in Advanced Class band segments.

This class of license has been dropping off ever since the FCC rewrote the rules and virtually did away with the class. Now, as renewals come up, the old Conditionals either drop out or become Generals. As you can

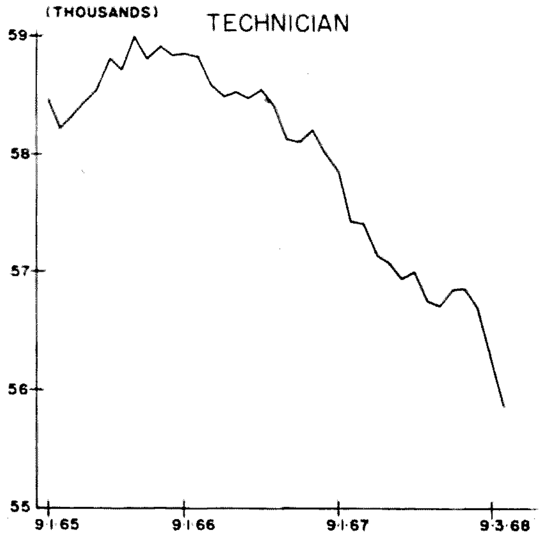
see, the incentive deal did not change the picture in the slightest. There is not any indication whatever of the Conditionals going for a higher license.



The interest of the newcomers reached bottom a couple of years ago and now is building up again. We really should make a major effort to get more and better hams into our hobby through a program of public relations.

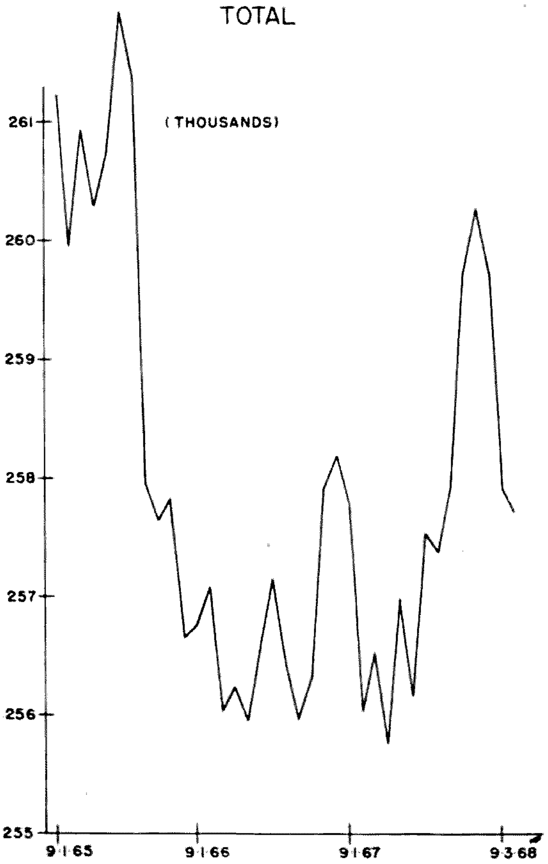
The drop-off has been steady for the last

two years. 2½% a year is not a reason to panic, but just the same I'd be interested in any ideas on where the Techs have gone.



That large drop-off in 1966 is probably more of a computer correction than a real change in licenses. In the last two years the number of hams has been very slowly growing, perhaps averaging out at about a thousand a year. It certainly isn't much like the good old days when our ranks were growing at about 10% a year! Perhaps we need new management?

Perhaps we should recognize that whether



we approve of the new regulations or not is besides the point now. They are the law and apparently will remain the law for some time to come. Our job now is to fall into line and get our higher class license as soon as we can. It is the responsibility of the ham magazines to make the transition as easy as possible. It is the responsibility of the radio clubs to encourage and assist members in getting their new licenses. We at 73 are doing everything we can think of to make it simple to pass the new exams.

Hamfests and Conventions

Hamfests and conventions, despite what you may have read recently, can be a ball and I try not to miss any more than I have to. During the last year I managed to get to the Long Island Hamfest, the Swampscott Convention, the National in San Antonio, the Saroc in Las Vegas, the Sideband in New York, the VHF in New Jersey and the Rochester Hamfest. Kayla managed to get to a lot that I had to miss, such as the Dayton Hamvention and many others.

Perhaps I should also count the 73 Hamfest up here in July. We didn't outpull the ARRL National as we did back in 1965, when we ran our last hamfest, but we did have quite a crowd and we had a lot of fun. I suspect that Hemisfair was more of an attraction than New Hampshire and its mountains. I enjoy New Hampshire a lot, but I do have to admit that I had a whale of a good time at Hemisfair and I'm glad I went.

Hamfests and conventions are important, I feel, to the spirit of amateur radio. Here we can all get together with the top hams of the country who are there demonstrating ham-TV or slow scan TV, ham-RTTY, ham facsimile, moonbouncing and all of the other special interests that go to make up our hobby of ham radio. A good convention will keep you hopping from one interesting session to the next.

How many contests have you entered at a hamfest? Code speed contests are simple to put on and are fun. Mobile operating contests are simple too. Fox hunting is great—it is the primary amateur radio activity for thousands of amateurs in Russia and several iron curtain countries. And how about working up some special contests, say perhaps one for the phone men with twenty telephones connected in parallel and a given time for all to exchange short messages or even just call letters with as many as possible. They will be yelling their heads off, if it works out any-

thing like a DX pile-up. I'm sure that an enthusiastic hamfest committee will be able to work out a number of events that will make their hamfest memorable—and will bring back even more the next year.

If the committee coddles the speakers they will get them back again too. All too often a guest speaker is left to just stand around until his speaking time comes. Some committees make sure that speakers are welcomed. The Swampscott committee puts on a special dinner for them, gives them badges and makes them feel glad they came.

Most hamfests don't rely too much on exhibitors as a drawing card for their hamfest, but convention committees know that the exhibits can make or break a convention. Every manufacturer in the ham field gets letters constantly asking him to come and exhibit at this or that convention. Some letters give the impression that the convention is doing the manufacturer a big favor by letting him display his wares. I realize that a good many amateurs have a basic feeling that everything in ham radio should be entirely home made and that manufacturers are an unnecessary evil. Without our manufacturers I fear that much of ham radio would still be hung up in the Tri-Tet Crystal Oscillator days and running 200 watts to a 6L6.

I get to talk with most of the manufacturers in our field and I think I know all of them pretty well. The best of them may be making a profit of 10% on his ham sales. That is, unfortunately, the exception. This means that any additional expenditure that he makes must be able to bring in ten times that expense in sales volume. A $100 magazine ad must bring in $1000 in sales. A convention booth must bring in $10,000 in sales just to break even, at the least. By the time you add the cost of the booth space, shipping the exhibit from the factory and back, plane fare, hotel, and etc., it costs more like $2000 for a convention.

How valuable is a convention to the manufacturer? Well, if you figure that he can talk to about two or three hundred prospective customers during the show, he has to do a powerful lot of selling to make it profitable. The average affair runs for about eight hours on two days, a total of 960 minutes. One customer every three minutes would total 320

Are there solutions to these problems? Of course. The convention committees that organize their club members to help make life easy for the exhibitors will find that they have a lot more displays. Show them the town, buy them a dinner, help them set up and pack their displays, offer them accommodations in members' homes. Spell them at their booth so they can see the convention, attend some of the talks, and get a snack. Most manufacturers have an interesting story to tell about their product and you could do worse than offer them a little time in front of an audience to talk and answer questions.

The secrets of putting on good conventions have been pretty well worked out. Hamfest and convention chairmen could do a lot worse than get in touch with the fellows who manage the Swampscott and Dayton conventions every year. These are the two most successful conventions year after year because they are well planned and are fun.

Lots of Prizes

There is much to be said for displaying all of the prizes prominently, complete with a commercial message beside each product. The winners can then come up and pick their own choice of a prize. This matches the needs of the winners to the prizes available and helps to cut down the discount selling of unwanted prizes after the hamfest, a process which is distressing to both the prize winners and the manufacturers.

Perhaps some publicity in the hamfest program could be given to the prizes. Also, as the prizes are picked out by the winners the announcer could read off the commercial message. If you show the manufacturer that it is to his advantage to give prizes for hamfests, there will be a flood of prizes.

Letters to the Editor

When I visit ham clubs I get asked a lot of good questions about ham radio, the ARRL, Don Miller, CQ, Incentive Licensing, the ITU, the IARU and other matters of general interest. The club members tell me that they enjoy knowing more about these things. Yet we hardly ever get any letters here at 73 asking about these things.

Yon might keep in mind, when you read something rotten about 73 elsewhere, that other publishers have a very good reason for hating us. 73, as far as we know, is the only ham magazine that is in the black. It will take more than name calling and cover immitating to change the pattern.

While I don't put much stock in editorials in other magazines calling me a scoundrel, you may and perhaps you feel that there are some questions that need answering. Ask away and we'll bring out the true facts.

Let's see them cards and letters, folks.

Be a Good Ham and Not a Bad Egg!

The mailman just delivered a small white envelope from the Federal Communications Commission and at last you're a ham radio operator! As you open the envelope and see your call letters for the first time, you join thousands of other hams in a new world of adventure. And, of course, dozens of these amateurs are probably right in your own hometown or area. If you want to enjoy the hobby to the fullest and form the most lasting friendships, resolve right now to be a good ham and not a bad egg!

Make a few rules for yourself about borrowing and loaning—and stick to them! It may seem a trivial subject but you'd be surprised how serious it can be.

For instance, imagine what happens to a budding friendship between two hams if one borrows an expensive tube tester from the other and then returns it several weeks later not working properly. Or what if the ham down the street says he desperately needs your jin pole to put up an antenna that weekend but lets it lie in his yard long enough to rust before bringing it back!

Oh, you'd never do anything like that, but who would have thought these fellows would either? They probably wouldn't dream of borrowing your car, camera, or lawn mower, but when it comes to ham radio, anything seems to go. Some hams feel that since we're all members of a great fraternity, they want to make sure they get the most from their memberships!

But what can you do about people who borrow? Of course, you can refuse to loan anything at any time and quickly become known as a sorehead. Yes, you may always have your possessions at hand, but you'll make it almost impossible to ever borrow anything yourself no matter how great your own emergency.

There are a few other tactics that are worth a try. In the first place, don't borrow anything yourself if you can possibly avoid it. You really ought to own a soldering iron, screwdrivers, wrenches and an assortment of nuts and washers, so don't pester some other fellow for these items. You'll be asking for return requests.

And if you want to look over a schematic in a current issue of an electronics magazine, for heaven's sake, cough up the 75 cents and buy it on the newsstand. Let the guy who subscribed to the magazine keep it on his desk. If you find you must borrow a back issue of a magazine, make a copy of what you're interested in and return it before the sun sets.

If you need an ohmmeter, voltmeter or equipment that will be beyond your budget for a long time to come, try to use it at the owner's home. Call him first and make sure you're welcome. If you're checking out a cumbersome kilowatt rig or something else extremely hard to move, ask the owner of the test gear if he would have time to come over and help you with the measurements. Chances are he would be tickled pink to bring his equipment and help you solve the problem right in your hamshack. This way there is no doubt how his property is handled and you'll probably learn a lot in the process.

If you do borrow a tube tester or anything else, don't ask for it until you're ready to use it, and then return it immediately. If you're delayed and can't take it back when you said you would, call the owner and tell him. Don't just keep it indefinitely. This is a sure way to make an enemy.

And another important rule of the game—don't ever loan anything you have borrowed to anyone else! It just isn't yours to loan; and believe me, if something is going to be

damaged or lost, it will happen when you have reloaned it. Then you really are in a pickle—you're still responsible for the borrowed article and you must explain that you had loaned it to someone else!

But what is the worst should happen while you're checking out your mobile rig with Tom's grid dipper and you drop it on the concrete driveway. Replace the dipper or fix it but don't returned a damaged article. If you take the broken dipper back as it is, the owner may say, "Oh, there probably isn't too much wrong with it," while gnashing his teeth, or he might give you a black eye.

If you have an accident with a borrowed item, even if an old tube flickers out, fix it first and then return it with explanation and apology.

On the other side of the coin, you'll be asked to loan things too. Put your name and call letters on a small tag and fasten it to tools or other items that might easily get lost in someone else's garage or shack. Label your magazines with your call letters and this will serve as a good reminder to the borrower that you want them back. There may be a lot of people you will loan to freely, but if you're approached by someone with a reputation for misusing borrowed gear, you can insist on accompanying whatever he borrows and then bringing it right back home. Or you can tell the little white lie that you just happen to be using what the fellow wants to borrow and just can't let it go.

After you have been on the air for several years, you will have scrimped, saved, and accumulated a fine inventory of test equipment and tools for your shack that will make a beginner blink with envy. He may have nothing more at home than a homebuilt CW rig and an imported key and you will be the first person he thinks of when needing to borrow something. No one objects to loaning equipment or tools to a beginner who needs a boost, but everyone's personal goal should be to accumulate what he or she needs to operate his equipment independent of another fellow. After all, John Smith saved his pennies for that $75.00 safety belt so if a sudden wind blows a limb across his beam antenna 80 foot up on a tower in his back yard, he can take care of it immediately. He didn't buy it for someone else to borrow and stack in his closet for a month or two.

The Golden Rule is just as applicable in ham radio as anywhere else. If you absolutely must borrow something, treat it as you do your own property and don't keep it one minute longer than necessary.

If you follow these suggestions carefully you'll never have to worry about being a bad egg—you'll be known by your friends as a real good ham!

. . . W5NQQ

73 Visits the Federal Aviation Control Center at Nashua N.H.

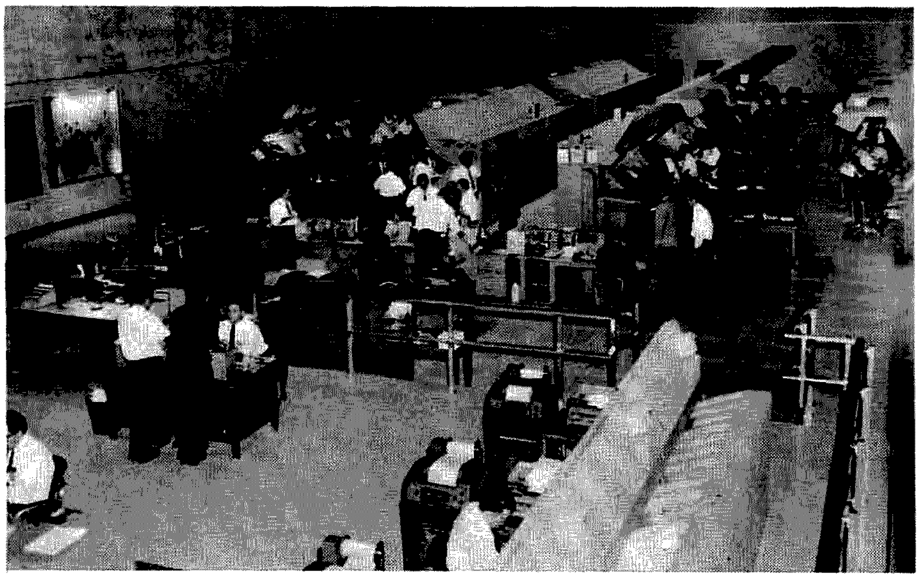
What are radio amateurs doing in the world of modern technology? One prominent public service business is air travel, and as we think about airplanes and public transportation we may remember a time, maybe thirty years ago, when airplanes were known human accomplishments but you did not see one very often.

A real, loud, amazing, *two-engine* airplane could upset anybody's schedule, if it passed over low enough. Some of them did. We all knew these were built and flown by men, but the thought of actually entering one and going up in the *air* with it seemed very unlikely.

I recall some magazine stories about Stratoliners, and it was believed that someday commercial flights at altitudes as high as 20,000 feet might be practical. This, men thought would be well above most atmospheric disturbances, and air travel would be very comfortable. That was in the days before jet engines, radar sets, and Clear Air Turbulence. Since then I have flown in passenger aircraft as high as 40,000 feet, and experienced the curious sensation of somebody hitting the plane with big soft hammers. Looking out the window I have seen other planes traveling with tremendous velocity in the opposite direction, and I have sat watching the wing (whose tip I could not see) while the pilot worked his way down through a stack in zero visibility, to land at last in a snowstorm.

Electronics in Air Travel

When you consider the problems, you may feel some surprise at the relative ease and reliability exhibited by airliners departing for some distant point, and getting there. The worst difficulties seem to be on the ground, getting to the airport, and from there to your destination. Some newspaper reports appear about those flights that don't make it, but think for a moment-there is an awful lot of air traffic. If all the successful trips were reported in any detail at all the newspapers could not publish very much



A general view of the many electronics consoles where flight controllers are observing and tracking aircraft.

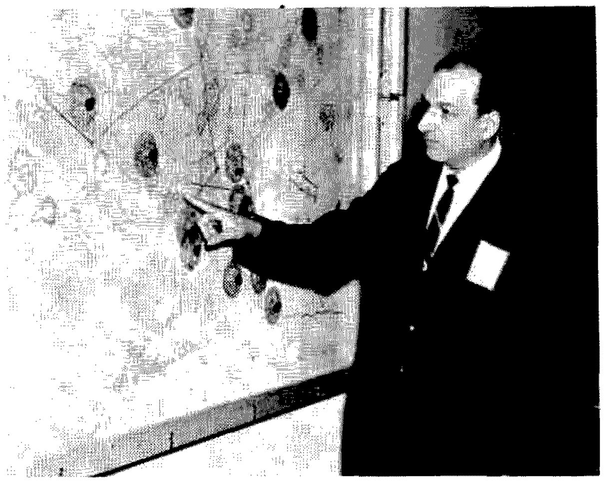
Looking at some of the more complex electronics gear. This is a system that adds maps to the radar display, and transmits the appropriate part of the resulting image to one of the radar repeated consoles.

else. Air travel has its hazards, but on the average it is a safe and very fast way to make long trips. If you avoid bad weather and those times when many other people are traveling you can get from New York City to San Francisco more comfortably than you can make a 300-mile bus journey, and, in about the same time. The air travel business has become a remarkable, huge industry.

A key part of this industry is electronics, appearing as data processing, telephone and radio communications, and radar observation and mapping. Are there radio amateurs in this work? Why not look for radio amateurs at the nearby Air Traffic Control Center? We came up with the name of Eli Nannis, W1HKG, and after a telephone call I went up for a visit. I expected to find something like a control tower or other conservative if slightly odd airport-type structure.

The Boston Air Route Traffic Control Center

A bit of careful navigation (following road signs) brought me to the Center. Isn't



Eli Nannis, W1HKG, is pointing out some of the characteristics of the New England area.

that odd? No airport, I thought. Seems to be no airport anywhere near here. Just this big block of a building with a microwave tower nearby, and some dipoles or longwire antennas. Looks like a manufacturing plant of some kind.

Walking up to this building, I rang the buzzer and shortly Eli Nannis came to the door. Going inside we walked down a short corridor and into a large room. It was more than that: it was a *huge* room! I was appalled. I was going to write something about this? Seeing that I might be approaching a state of shock, Eli considerably conducted me along one wall (I felt like a mouse invading an auditorium) and we went into the Center's amateur station, WA1HOB

It turned out the Center has a rather large and quite active ham radio club. There are hams from all parts of the Center, which employs about 400 people and is in business 24 hours per day, every day. The ham station consists of a Galaxy transceiver, some test gear, and of course an SWR bridge. The setup there can be operated from mains power, the Center's emergency power, or from car batteries, and can double over for emergency communications if necessary. An educational program is continuing for the improvement of hams' technical and communications backgrounds, and several new amateurs are expected to receive their tickets shortly.

After we visited the station, and I had recovered slightly from my shock at seeing the size and complexity of the Center, we discussed the work that is done there. Basic-

ally, its purpose is to oversee all air traffic, except a few light planes, within the area between northern Maine south nearly to New York City, and west to slightly beyond Syracuse. Air traffic within five miles or so is controlled from the airport control towers, and is not a responsibility of the Center.

There are four technical areas in the Center, reflecting the four general kinds of work carried on there. They are communications, display preparation, data processing, and the flight control area.

I was very surprised to find the Center has no radar or other direct connections with the outside world of air traffic. All radio gear and radar systems used by the Center are situated at appropriate places over the control area, and linked to the Center by microwave or telephone systems. For instance, a flight controller handling traffic near Syracuse uses a radar display that is generated at Syracuse, not in New Hampshire. Since any controller can talk with as well as observe any plane in his area, and there are many areas and controllers, the Center has a communications system that certainly appears large enough for a fair-sized town.

The equipment that generates the displays used by the flight controllers is on the same lower level as the communications system. Several large cabinets contain some rather unusual gear that combines incoming and locally generated displays, and prepares them for use by the controllers on the floor above.

At one end of the building, on a large raised platform, there is a large Univac computer. It is to be replaced by a larger

Here Eli Nannis is following an aircraft on one of the many radar repeater consoles.

one, I understand, within a year or two since it is having some difficulty keeping up with the work. This computer prepares flight information by use for the controllers, and reads it out on the machines visible in the lower RH corner of the large photo. This computer can accept information from other computers in adjacent flight control zones, without human assistance, so that controllers are promptly informed of flights entering their areas or passing over on long trips.

And at the other end is the actual flight control area, consisting of many small consoles, each manned by a group of two or three workers. The consoles at the left hand side of the room are operated by men controlling flights above 20,000 feet, and those on the right are for flights below 20,000 feet. Each console displays only a rather small part of the overall picture of the entire area.

How the Center Works

All commercial and military pilots, and many private pilots, file flight plans with the FAA shortly before takeoff. These list takeoff and landing times and places, and proposed schedule in flight. Fed to the Center's computer, these figures are checked against other flight plans, and changed if necessary to avoid hazardous interference possibilities. Finally, the computer prints out information slips for the flight controllers, carrying the data each one needs to follow that flight across his screen.

The controller sees the plane as a blip on his screen. He notes the plane's designation, bearing, speed and altitude on a small piece of plastic (called a shrimp boat) which he pushes across the radar display to follow the appropriate blip. If he wants to talk with the pilot he is able to communicate through the elaborate phone and radio system, and can ask the pilot to activate a transponder in the plane. This generates a brief but prominent change in the blip, and the test is regarded as most successful if the appropriate blip flashes, and most needed if some other blip flashes. Positive identification is made very quickly in this way.

Each controller is responsible for the safe flight of up to ten (or 20, in emergencies) aircraft across his area. He gets about sixteen months of training, on special simulated displays, before he goes to work as a controller.

As Eli was explaining this to me, something was gaining my attention. I looked at one of the displays close up and finally it struck home: These looked like PPI displays, and they were green as you would expect, but they seemed to show TV scanning lines. In fact, they appeared to be TV displays, not radar displays. I asked Eli about this. What was the purpose of it?

Some Very Practical Electronics

That explanation took some time, and we visited some parts of the building again as the various parts and functions fell into a clearer picture.

The incoming radar displays are not very good for flight control work. For instance, beacon sites and airways are simply places on the map and there is little or nothing to serve as accurate reference for radar navigation control. Airways do not reflect radar waves. And so the map is added at the Center. A flying spot scanner does that job.

A sharply focussed spot moves across the face of a fast-phosphor tube (the trace is quite blue, almost violet) in synchronism with the radar trace. A map is placed over this display. Since the map is drawn on transparent material, its lines appear as positive or negative lines when added to the incoming radar picture. Very little electronics is required to do this job, most of it serving to keep the flying spot trace and the map in synchronosm with the radar display. The combined signals are presented on the face of a special image memory tube, but this picture is off-center so that only a portion of the area visible to a given radar set appears on the memory tube phosphor.

This is because the same big display can be fed to several memory tubes simultaneously, each tube getting an area that is interesting to one flight controller. A TV pickup tube assembly then reads off the image for use in one or more flight control consoles. Since there are several of these systems, a data processing system, and many communications systems, it is evident there is a lot of electronics installed in the BARTCC.

The Future

Hams thinking about their future in electronics should be very interested in the FAA's work in aircraft safety and navigation. The field is rapidly developing in complexity and sophistication, and although it's pretty elaborate right now it was my impression that you'd really be getting in on the ground floor. Right now, electronics technicians get about $9,000 worth of training over a period of six months before they are qualified, and this can be expected to be worth more and take longer as proposed new gear and systems are installed and made operational. ■

Poor: 9, 10, 26, 27.

($1,000,000 TVI Suit from page 37)

their findings would be reported to the Miami office of the FCC which has jurisdiction in this case.

On October 25, I spoke with Mr. Gilbert, the Engineer in Charge of the Miami FCC office, to see if a determination had been made in the case. He said that the FCC could find no cause to limit Mr. Gridley's operation and that Mr. Eggers' attorney had been notified to that effect. He said that he considered the case closed inasmuch as the FCC no longer had jurisdiction over what is in essence a dispute between two neighbors.

On October 26, the original pre-amplifier was re-installed at the TV antenna upon the insistance of Mr. Eggers. The Jerrold amplifier and the high-pass filter were removed. This TV set is, therefore, in its original configuration, which exhibited the maximum amount of interference.

On October 31, a suit was filed in the Circuit Court of Sarasota County against Mr. Gridley. Among other things, the suit states:

> "That said radio station was erected and is maintained in a negligent and unskillful manner, and by reason of this negligence and want of care in the construction, operation and maintenance of said radio station since the year of 1958, Defendant still does maintain a nuisance, causing much discomfort and vexation to your Plaintiff by not allowing him to enjoy his radio and television sets because of this constant and considerable interference, and this aforesaid nuisance constitutes an electronic invasion of privacy in the home of the Plaintiff."

The suit asks that Mr. Gridley be restrained by injunction from maintaining or using his amateur station and that Mr. Eggers recover $1,000,000 damages.

Mr. Richard V. Harrison, attorney for Mr. Gridley, has contacted the ARRL General Counsel in Washington and has requested support in this matter. Mr. Harrison has also moved that the case be heard in the Federal Court in Tampa, and that Mr. Eggers be enjoined from publishing in the newspapers any material referring to Mr. Gridley or to "ham operators." A total of five advertisements containing "editorials" have appeared in the newspaper since the start of the case.

It is understood that a hearing on this case will be held in the Federal Court in Tampa on January 8, 1969.

The TVI Committee believes it has exhausted all possible methods to effect a solution to this interference problem. However, a final solution cannot be effected until the complainant agrees to cooperate by allowing the necessary corrective action to be performed. Nevertheless, the committee will continue to monitor the events as they occur and stands ready to assist if requested.

A note from Grid points out that there never has been a precedent set in a suit of this type in ham radio and that an adverse ruling, no matter how unlikely, could mean the end of amateur radio as we know it today. Grid needs help, legally and financially, to see him through this nightmare.

CW Only Here, OM

As a true believer of the delicate art of CW, I used to wonder since World War II, if I was still living in the age of high button shoes and buggy whips, but I no longer do, and here is why:

I made my conversion at a tender age from the life of a normal, red blooded American boy to a strange character who spent long night hours listening to weird noises from the 201A's in a super-regen receiver. The sheer joy of first copying completely a message from start to end has seldom (I siad "seldom") been equaled to this day. I was a superior being—I was in an esoteric society of superhumans who had their own language, and greatest of all—I was privy to secret conversations coming through the night in fair weather and foul.

Since 1928 (my "ticket" year) I have steadfastly held my head high and refused to be seduced by the "phone" boys—or as we now say the "SSB" types. "Lips that touch liquor shall never touch mine" were mild compared to my firmness that, "A hand that caresses the bug shall never hold a mike." My rationalization for this attitude was a thing of beauty and joy forever. I said, in my pristine purity, "I talk all day on the telephone, so why should I spend my precious time shouting into a mike!" For this I have suffered the opprobrium, slurs, and downright insults of my fellow hams, but I have resolutely turned my cheek.

Now after 38 years of "CW only" (I started young—so none of that "Old Timer" stuff) I feel my lonely stand against the ubiquitous "phone man" is slowly being vindicated. I am sort of a strange breed that can best be described as a "DX ragchewer" or a "Ragchewing DX'er." I do this by sitting quietly in front of my 75A4 watching the heat waves rise from the Henry 2K final and slyly swinging around the wide spaced single band Yagi to those directions wherefrom the sweet and pure sigs come for me to snare. When this occurs I then subtly start questioning the victim in English, French, or Spanish to encourage him to break the deadly pattern of the "RST, QTH, QSL, 73" hackneyed QSO's heard constantly on 14 MHz. Sometimes I succeed, sometimes I don't, but when I do I get some interesting answers. Among these answers comes forth the fact that a number of dedicated phone men are reluctantly deserting the ranks of SSB for the honorable art of CW. Why? Mainly, because they are bone tired of the incessant flow of chatter, endless repetition, and the use of "cute" phrases. They want to again enjoy the crisp, clear interchange of ideas, thoughts, and information through the use of CW which by its nature forces clear thinking into few words. Objectively, I think this is good for amateur radio. It gives a healthy transfusion between disciplines and keeps alive that spark of uniqueness in amateur radio of "Let's do it differently, and better."

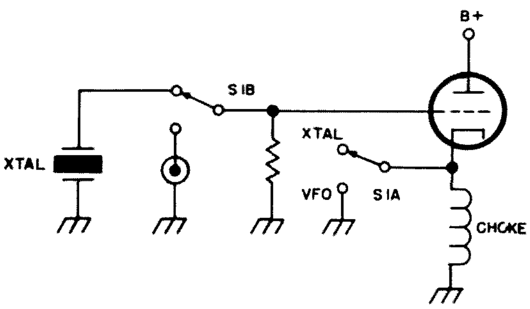
. . . W6EKN

HI-HO-HUM

Are you getting signal reports that you have a sixty cycle hum and your modulation is distorted, when you use your vfo? Is it possibly a leaky pair of electrolytic condensers in the power supply of your transmitter? Or, could it be a broken shield on your mike cord? Nine times out of ten the vfo is causing the hum.

How come it is the vfo? In commercial radio amateur or "home brew" trsnsmitters, the cathode of the oscillator tube sometimes has a choke or a choke and resistor to ground. Now this is fine if you use a crystal but if you use a vfo with the choke or choke and resistor still in the cathode circuit, you are above ground and there is the hum.

To cure this problem, the cathode must go straight to ground eliminating the choke when you use the vfo. A DPDT switch (see **Fig. 1**) will make it easy for you to use a xtal or a vfo without any hum.

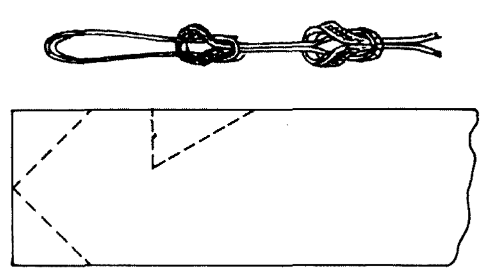


. . . K6GKX

Superslingshot for Stringing Antennas

Hams have often used trees to support antennas. Unfortunately, the trees could not always support the ham as well. The casualty rate is somewhat lower for those who put the antenna in the tree by the bow and arrow method, but a suitable bow may run ten or twenty dollars and there's all those arrows too. You can always try throwing something, but if you're fat and forty or just plain out of shape, you may find that heaving a chunk of stone almost straight up feels harder than it looks.

My solution is better than a wrenched elbow and cheaper than a good bow. Buy a package of rubber bands, size 16 should do, and link fifty of them in a row as shown in the figure. You must loop the end ones as shown or the string will come apart.



Take 18 inches of 1x2 wood or broomstick and cut the head as shown. Lay out a light nylon string 2½ times the height you want in large loops and attach the top end to the tail of the "arrow". Now, using a tall ladder and the rubber band string as a giant slingshot, notch the arrow, pull back as far as the bands will allow (3-5 feet), aim and let fly. If more power is needed to put the arrow over the limb of the tree, heavier bands will give your arrow more fling. So what if the neighbors think you're crazy, they know you're a ham.

. . . WA4VQR

Warning!! If the bands should break, the backlash could be severe. Draw to the chest, not to the eye! Ed.

104 Easy Transistor Circuits You Can Build, by Robert M. Brown

A hundred and four useful circuits, ranging from really simple or novel devices such as a light-activated oscillator to receivers, transmitters, and test instruments. There is something for any interest, or any wallet, in this book, and many of the circuits are of the extremely uncritical variety that can be assembled easily from junk-box parts if other materials are not available.

For instance, a power supply circuit described in the introduction, uses a simple current-regulating circuit in place of a zener which may be hard to get, and works very well with almost any available transistors of the correct polarity. The introduction also contains several paragraphs on substitution of available transistors for those listed in various projects.

Specially noted in the book were projects for several code practice oscillators, some CB gear, VHF as well as HF circuits, several test generators, and an efficient battery charger that will automatically switch over from charge current to a small trickle current as soon as the battery reaches full charge.

"104 Easy Transistor Circuits You Can Build" is available from your distributor or from Tab Books, Blue Ridge Summit, Pa., 17214, for $6.95 in hardcover (recommended) or $3.95 in paper.

99 Ways to Use Your Oscilloscope

If you have a 'xx 'scope, this book will be invaluable to you. If you don't have a 'scope then get one. Also get the book. It shows you how to test just about any circuit you are liable to run into, complete with the waveforms that you should find. Servicing color? Here is the info. What to do with an IC circuit? Transistors? All right here, with waveforms. Curve tracing for transistors? Diodes? Zeners? Here too. TAB Books, Blue Ridge Summit, PA 17214. Probably available from your local distributor for $6.95 hardbound (best) or $4.95 in paper. This book will give new life to your 'scope.

ANNUAL W2-DX ROUND-UP Saturday, March 22, 1969 (Saturday prior to IEEE Convention) at Holiday Inn of Newark, 430 North Broad Street, Newark, New Jersey. Starts 1 P.M. Ticket basis—afternoon program only, or total package with prime rib banquet. Afternoon program will include talks on speech processing, antenna performance, DX panel on "How To". Door prizes. Conveniently reached by train, subway, auto, and bus. Further details call W2LA. Also call 201-226-4545 or 212-344-2997 both daytime.

---

500 GREAT CIRCLE bearings, return bearings, distances, time differences, zones, computerized to your QTH. $3.00. Samples, 25¢. Bearings, 122 Lockhart, Princeton University, Princeton, N.J. 08540.

HALLICRAFTERS HT-37. $210, good condition, clean, no rust spots, and low mileage. Bob Koepke, W9IHI, 344 Oriole Lane, Madison, Wisc. 53704.

ALL HAMS, particularly college students, interested in pure physics and physics-philosophy, are invited to join Die Physik Gruppe, a group which will get on the air regularly and ragchew physics, especially pure physics and physics-philosophy. Please write Aron Faegre, WA9FJG/7, Box 318, Reed College, Portland, Oregon 97202. Discussions will not be in German!

---

3 PLASTIC HOLDERS will frame and protect 60 cards, $1.00—or ten holders $3.00. Prepaid & guaranteed. Patent 3309805. Tepabco, Box 198N, Gallatin, Tenn. 37066.

RECEIVER BAND changing switch 25¢ postpaid. Send for our surplus electronics parts and equipment flyers. Bob-Frank Electronics, PO Box 1327, Harrisburg, Pa. 17105.

ORIGINAL CONDITION, 1923 RCA radio. Has oscillator, wave length, loop regeneration knobs, tubes and transformers. Excellent condition for age. Best offer over $100. W. C. Smith, 8679 45th St., Glen Avon, California 92509.

---

19 ASR TELETYPE for sale. A-1 mint condition, factory reconditioned. $150. C. Vinson W2GJJ, Larkspur St., Yorktown Heights, New York 10598.

REGULATED POWER SUPPLIES, without transformers, .6-4 AMP, $2.75 to $8.50. Zeners, thermistors, $.25. 10A Triac, $1.75. Diodes, $.05. Nixies with driver, Burroughs #B6091, $9.50. Catalog. Murph, 204 Roslyn Ave., Carle Place, New York 11514.

LONG RANGE TV reception easy! Booklet outlines methods to receive distant TV stations using inexpensive materials. $1.50 postpaid. PRACTICAL PLANS, Box 56-K, Killeen, Texas 76541.

WANTED: ½" paper tape for Boehme CW keyer. Send your price and amount available to Robert R. Smith WB6ODR, 13209 Idyl Drive, Lakeside, California 92040.

COLLINS: 51J4 w/3kc filter, excellent condition, $700; KW-1 transmitter, excellent condition but needs bias transformer available from Collins for $53, $700. Shipping paid. Paul Reid, 405 4th Place, Merritt Island, Florida 32952.

VHF GEAR. Three Clegg 22'ers, $160 for one, 10% off for two or all three. 6 Meter Gonset Communicator III, $130. No personal checks. Barrie C. Hiern, K5SGP; 1506 Cross Lake Blvd., Shreveport, Louisiana 71109.

FOR SALE: 6 meter Hallicrafters AM SR-46 transceiver w/HA-26 VFO and Mobile kit. Mint Condition, $100. Joel Eschmann K9MLD, 2036 Erie Street, Racine Wisconsin 53402.

WRL'S USED GEAR has trial—guarantee—terms! HW22—$89.95; Swan 350—$279.95; Galaxy 300—$139.95; V—$249.95; Vmk2—$299.95; HX500—$269.95; HT37—$199.95; NCL2000—$449.95; SB300—$229.95; NC155—$119.95; RME6900—$149.50; Collins #312B5—$199.95; hundreds more. Free "blue-book" list. WRL, Box 919, Council Bluffs, Iowa 51501.

RUSSIAN AMATEUR TRANSMITTER type CCCP-SVIAZ for sale, best offer accepted. George WA4NQR, 102 Willow Rd., Savannah, Georgia 31407.

---

25 YEAR COLLECTION electronic sound equipment, tape recorders, speakers, microphones, parts, technical magazines, collectors' items. Los Angeles 383-8718 after 8 P.M.

RUSSIAN TYPE CCP VSIEM amateur transmitter for sale. Best offer. W4MQU, Jacksonville, Fla., 1563 San Marco Blvd.

RTTY GEAR FOR SALE. List issued monthly, 88 or 44 MHy torroids 5 for $2.00 postpaid. Elliott Buchanan & Associates, Inc., 1067 Mandana Blvd., Oakland, California 94610.

DAYTON HAMVENTION April 26, 1969: Sponsored by Dayton Amateur Radio Association for the 18th year. Technical sessions, exhibits and hidden transmitter hunt. An interesting ladies' program for XYL. For information watch ads or write Dayton Hamvention, Dept. S, Box 44, Dayton, Ohio 45401.

Editorial Liberties

OK, I finally allowed the camera to take a picture of the Editor. So . . . stop nagging, already. On the left is the camera eye's view of your editor. A benign, friendly, motherly gal. On the right is a cartoon I found taped to the file cabinet next to the drafting table here at 73. This shows what at least one of my fellow workers sees in me! Perhaps I should mend my ways?

For years, our annual surplus issue came out in June. At the request of many of the surplus dealers, we advanced it to March. The complaint is that June is not a "project" time. Perhaps October would be even more appropriate, since with the advent of the long winter months, those living in the north abandon boats and other outdoor activities, and begin planning for inside building projects.

In any case, there is a dearth of surplus articles coming across my desk. Following World War II, the conversion of surplus constituted much of our amateur equipment. These days, there doesn't seem to be much new material. Most of it finds its way into the MARS programs, and much apparently is simply destroyed, since it is highly classified. I wonder if amateur radio may not be nearing the end of another era?

It is becoming increasingly evident that the number of new hams is decreasing each year. It is also evident that the number of hams who are going for the higher class licenses, is not up to the expectations of either ARRL or FCC. This brings us to speculate on various reasons for both situations.

There was a time when one could walk into an FCC Field Office and request to take the exams. There was a later time, when mornings were available each day during the week for those wishing to take the exam. Now, you look at the list of FCC offices and times of examination, and the restrictions are pretty grim. In many cases, you have the choice of getting to the office at 0800 the third Friday of the month, or not taking the test.

This is a hardship. For the person who lives in a large town which has a Field Office, perhaps it is not too bad. I live 80 miles from the nearest FCC office. This is 80 miles, for the most part, of winding country roads where the speed limit is about 40. This means a two hour drive on a work day morning, arriving in a state of physical and psychological exhaustion from fighting the morning traffic, and facing the noise and confusion of perhaps 50 other examinees in one room.

I haven't copied code with a pencil for many years. I use a typewriter. In a crowded room, a typewriter makes more noise and confusion, so FCC says I can't use one. I've been using a typewriter for so long that I can hardly write anymore. At least not so anyone can decipher my scrawl. So, I have to go back to learning how to use a pencil before I can qualify for the Extra.

I do not advocate easier exams. I do think it would be a not too difficult task for the local Field Offices to make examining conditions more relaxed and less restricted.

I suspect if the FCC offices were not so full, there would be fewer failures.

. . . Kayla—W1EMV

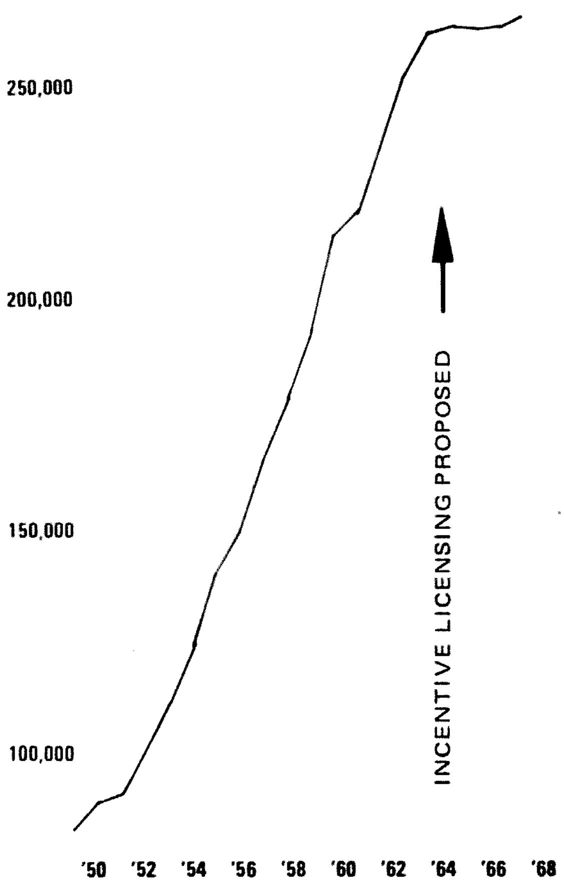
...de W2NSD/1

Wayne Green

The chart below is based upon the FCC figures for the number of amateurs licensed each year for the last twenty years. As you can plainly see, the amateur ranks were swelling at the rate of about 13,000 per year fairly regularly until 1964, when the growth virtually stopped.

While the sudden stunting of amateur growth is strangely coincident with the announcement by the ARRL of their Incentive Licensing proposals to the FCC, I realize that I have been perhaps a bit tedious in my finger pointing at this particular outrage (in my view) and that there may be other factors which brought about the results which I predicted.

Be that as it may, there are several reasons why it is important for us to get that growth curve back on the track. Though portions of our lower bands are reasonably active, there are wide areas of our higher bands that desperately need more activity.



We have acres and acres of room for growth in VHF bands. And if we don't start growing into these frequencies there is not the slightest question that we will start losing them. I don't know if it is necessary to open up the top end of ten meters to the Novices, but I do know that we darned well better do something to get some activity up there or else it could turn into another Citizens' Band, or even worse. Well, it probably couldn't be worse. Ten was a lot more active ten years ago at the time France made a major try to get the ITU to authorize them to use the top megacycle of ten meters for local low powered communications with the proviso that amateur radio could continue to share the band as long as it did not interfere with their communications. Fortunately this rule change was voted down at the time.

Pardon my digression, but I wanted to show that every one of our frequencies is badly wanted by other services and you can bet that they are ready to pounce on anything we leave unused for any length of time.

The use of our frequencies is only one part of the protection we can give them. Frequency allocations are a political matter, unfortunately, and it is important that we recognize this and act accordingly. We all realize that amateur radio is of tremendous importance to our country. We know that the electronic industry and the communications industry in our country could not possibly have grown at the rate it has without the hundred thousand or so amateurs who are working in them. We know that our preparation for the last war would have been much much longer if we had not had tens of thousands of amateurs available as radiomen, electronic technicians, and teachers. Communications and radar were of critical importance in our winning the war and these might have taken years longer to press into effective use had it not been for our amateurs.

We need only look around at other countries to see the importance of radio amateurs. Where

(This goes on and on on page 77)

Modernizing the TCS Transmitter

Robin Gaardsmoe K3UUL
11831 *Charles Rd.*
Silver Spring, Md. 20906

The TCS transmitter is as fine a piece of workmanship as can be found. However, it suffers from a common problem with surplus gear—it was designed to perform as part of a group of equipment and in a manner useful to the military. Herein are some simple changes which will fit this fine instrument into typical amateur patterns of operation. The word simple must be stressed. There is no point in spending days stripping the entire circuitry and building a whole new transmitter in the frame. These modifications will require about four to six hours and very little in the way of parts or machining.

There are four logical steps to the conversion of the TCS. First, if you do not have the companion power supply, one must be built. Obviously, this will require much more than the aforementioned four hours. But it is likely that a better supply can be built, by the ham with a typical stock of "junk" parts, for less than the original version can be purchased. (i.e. under $40.00).

Second, conversion to cathode keying will be covered. As designed, the TCS is keyed by applying and removing B+ on the final tubes, at a keying rate, with relays. In the AM mode, this is a satisfactory method. When using CW, however, this type of keying is completely unacceptable.

The third phase involves modification of the output circuitry to provide optimum transfer of power to a matched 50 ohm line. This is the antenna system used by the author, and therefore, the only one for which specifics can be supplied. The basic concept of the output tank will be discussed in hopes of enabling those using tuned lines, non-resonant antennas, etc., to experiment and find a solution suitable to their particular installation.

As a final phase, we will take a brief look at boosting the audio of the modulation stage, a necessary step if AM use is contemplated.

Power Supply

If you desire to build a supply for your TCS, the first step is to change the power plug, P_{101}, to a common type. Fortunately, the hole occupied by the existing P_{101} is exactly the right size for an octal socket. So, remove the leads from P_{101} and label each by pin number as you move them aside. Secure a male octal plug, the type with a locking ring, and install it in the hole formerly occupied by the multi-pin P_{101}. Re-connect the leads according to **Table I.** In addition, connect a 0.01 mfd disc capacitor to ground from each of the new pins except number 5.

Old pin #	New pin #	New Function
2	1	Final tubes B+
7	2	ac on loop
12	3	ac on loop
13	4	12.6 vac—filaments
15	5	Ground
14	6	Oscillator & Buffer B+
16	7	12.6 vdc—relays
—	8	Relay switching—see "keying mod."

TABLE I.

The remaining leads which are not shown connected in **Table I** should be removed or tied back and insulated. They are not required when the transmitter is used without the companion receiver.

The power supply is straightforward and requires little discussion to supplement the schematic, **Fig. 1.** As designed, the TCS power supply provides 400v B+ on the final tubes. However, this voltage level will not realize full power output, approximately 65 watts, with some output configurations. The 1625 tubes used can easily operate with

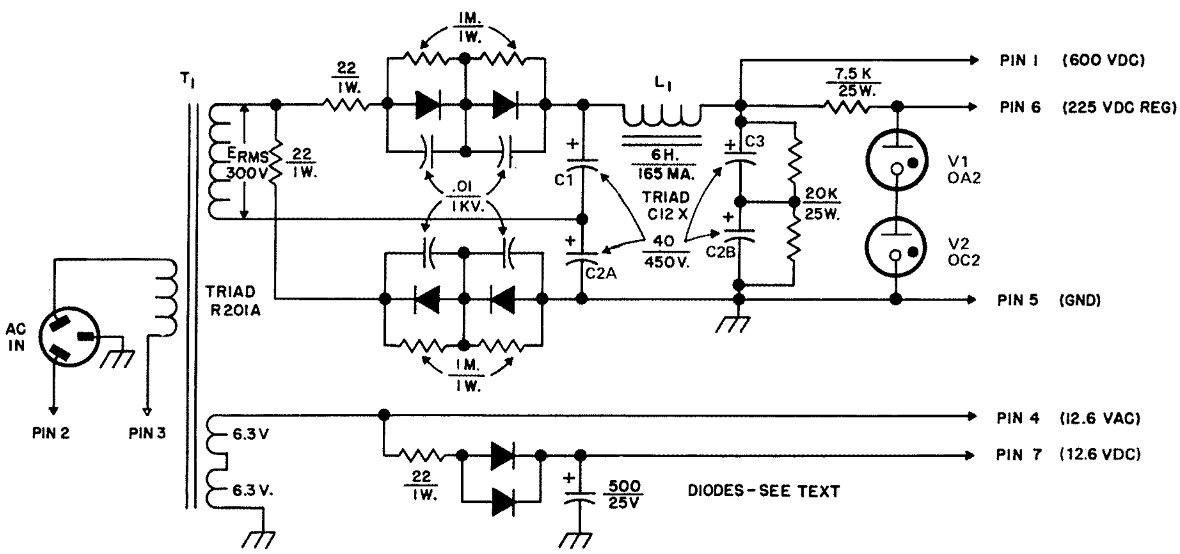


Fig. 1. Schematic diagram for the TCS power supply.

600 V on the plates. Therefore, selection of a high voltage secondary for the power transformer may range between the 400 V to 600 V level with output power varying accordingly. The transformer shown in **Fig. 1** uses a voltage doubling rectifier, yielding about 600 Vdc at pin 1. It is an excellent combination of high voltage and filament windings at a reasonable price, but is by no means the only one available.

Medium voltage is regulated at 225 V by V_1 and V_2 in series. The load on the regulated line is constant, therefore VR tubes can be used despite the fact that the load may exceed the rating of the tubes. Note that C_1 and C_3 must be separate units. A common negative, dual type will not do. C_2 may be a common, can-negative type, however.

Since everyone has a different source of the hundreds of types of silicon diodes on the market, a stock number is not called out. When selecting diodes, use the rule-of-thumb:

$$PIV_{total} = 3 \times Vac_{rms}.$$

Thus, using the transformer shown, $PIV_{total} = 3 \times 300 = 900$ V. If your diodes are rated at 400 V PIV, for example, you *must* use three of them in series in each leg. Failure to observe this rule will invariably cost you a diode or two. Place a .5 to 1 megohm, 1 watt resistor and a 0.01 mfd, 1 kV disc capacitor in parallel with each diode whenever two or more are used in series, in order to equalize current distribution and damp voltage spikes. The 22 ohm, 1 watt current limiting resistors in each leg are essential in a capacitor-input power supply.

12.6 Vac is required for the filaments. This particular transformer has two 6.3 Vac windings of equal current rating. If you connect two such windings in series out of phase, there will be no output. Should this occur, simply reverse one winding connection.

The entire supply can be housed in a 4 x 5 x 6 inch minibox and mounted on the rear of the transmitter case.

Keying modifications

Following is a step-by-step procedure for converting to cathode keying. It is an extremely simple operation, literally requir-

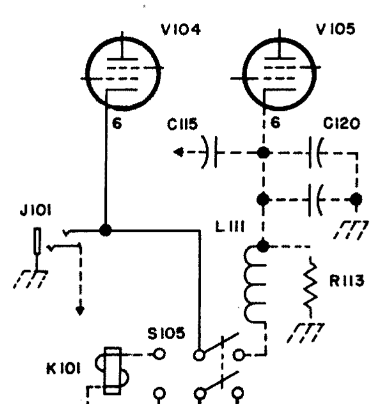

Fig. 2. Converting the TCS to cathode keying. Solid lines show conversion.

ing only fifteen minutes, but well worth while. (See **Fig. 2.**)

1. Remove the transmitter from the case and lay it upside down. locate X_{104}, the socket of V_{104}. Next, locate pin 6. Pins 1 and 7 are the large tube pins—the filaments. Looking down on the bottom of the socket from the front, the left-hand large pin is number 7. Count counterclockwise to pin 6 and unsolder all leads from it. These leads are all heavy bus-wire. Push them clear of the socket and solder them together again. A tie-point is not necessary.

2. Locate the "tip" contact on the three-way "Key" jack, J_{101}, and unsolder the two leads from it. Move them temporarily aside. Now solder a five inch length of hook-up lead to this contact. Route the other end to the "Voice/CW" switch, S_{105}.

3. On S_{105}, unsolder the solid white wire on the center contact of the side *away* from J_{101}. Remove or tie back and insulate this lead. It will not be used.

4. Connect a lead between pin 6 of V_{104} and the contact just vacated on S_{105}. Also solder, at the same contact of S_{105}, the five inch lead from J_{101}.

The cathodes of V_{104} and V_{105} are now lifted from ground and will be keyed during CW operation. On AM V_{104} is turned off and V_{105} will be keyed by a normal PTT operation. All that remains is to provide for the switching of K_{102} and K_{103} when going from receive to transmit and vice-versa.

5. Remove the large ground screw from the front panel. About one inch directly beside this drill a clearance hole for a #10 screw. From the front insert a ½ inch long #10 screw and re-connect the ground leads from the old ground lug. Secure them with a nut.

6. Enlarge the old ground-screw hole to accept a SPST toggle switch. Mount the switch and connect one contact to the new ground lug beside it. To the other switch contact, connect the two leads previously removed from the "tip" contact of J_{101} (Step 2). To this same switch contact, connect a lead to pin 8 of the "Power" plug, P_{101}.

Steps 5 and 6 have added a "Send/Receive" switch to the front panel of your TCS. In addition, pin 8 of the power plug is paralled with it and may be used (in

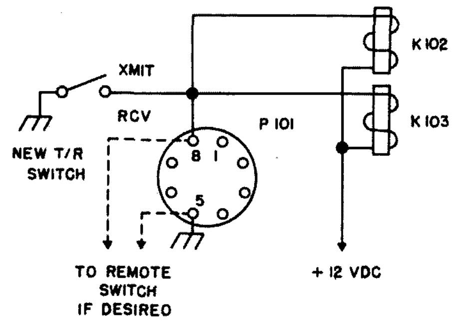

Fig. 3. Steps 5 and 6 of keying modification.

conjunction with pin 5) as a remote switch or relay control of the same function.

Output modification

The antenna circuitry of the TCS is designed to load an unmatched 20 foot whip with single-wire feed. Series inductances are provided, internally and externally, to permit reasonable matching over the frequency range. At best, this is an expedient system and can be vastly improved upon.

At this station, a 23 foot, base-loaded vertical is used with 50 ohm coax feedline. From a space economy standpoint, this is perhaps the most desirable antenna system for the low frequencies of the TCS. Certainly, a more efficient system would be an end-fed long wire. but this requires infinately more room.

7. To begin with the modification, disconnect and remove E_{105} and E_{107}, the "Receiver" and the "Antenna" terminals. Enlarge the two holes to accept coax connectors—type UG-657 (BNC) connectors fit the holes without the need for enlarging. Re-connect the two leads to the new coax connectors.

8. Next, disconnect and remove the roller-coil, L_{108}, marked "Antenna Loading". Temporarily leave the two bus leads (from L_{107} and S_{103}) hanging. The coil is held in place by the four corner screws of the panel-plate, and two screws, in the rear of the roller-coil, attached to a bracket. By removing V_{104} and V_{105}, the latter mounting screws are accessable.

9. Remove capacitor C_{121} and the ceramic stand-off on which it is mounted. In place of this, mount a similar type capacitor with a value of 1000 mmf (i.e. Centralab 858S-1000). This capacitor mounts with one end grounded directly on the transmitter frame. Refer to **Fig. 4** for later connection of the other end of the new C_{121}.

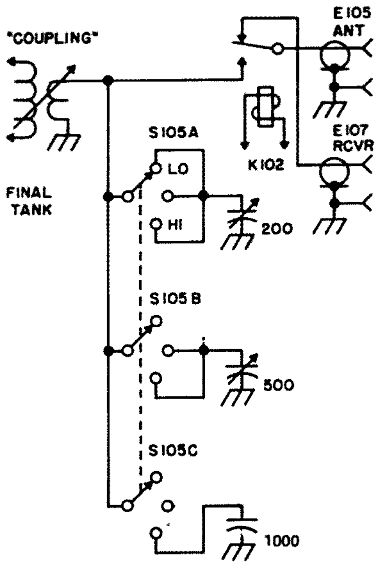

Fig. 4. TCS output modification.

10. Next, using 1/16 or 1/8 inch aluminum plate, fashion a cover plate for the hole from which L_{108} was removed. The face-plate of the roller-coil may be used as a template for the perimeter shape and position of the four corner mounting-screw holes.

11. Secure one of the myriad types of ac-dc receiver tuning capacitors having two gangs. Almost any will do, so long as one section will tune to about 500 mmf and the other around 200 mmf. These values are certainly not critical. Mount this capacitor on the cover plate you have just made, making sure the rotors ground to the transmitter frame. Before mounting, connect about six inches of buss wire to the stators of each section, positioned towards S_{103}, the "Antenna Condenser" switch.

12. Carefully bend the buss lead from L_{107}, left by the removal of the roller-coil toward the relay K_{102}. Solder it to the same relay contact as the lead going to C_{121}.

13. Now, remove all wiring from the "Antenna Condenser" switch, S_{105}. It will be necessary to carefully straighten the buss wire lead from K_{102}, referred to above, in order for it to be long enough to reach the proper contact when rewiring S_{105}.

14. Refer, now, to **Fig. 4** and make all connections at S_{105}.

When completed, this switch becomes a Low-Medium-High capacitance range switch, all in parallel with the antenna link of L_{107}. By proper selection of range, and experimental balancing using the "coupling" control and the new "antenna loading" capacitor, you can obtain optimum power transfer to a matched 50 ohm antenna throughout the frequency range of the TCS.

Essentially, the requirement which must be satisfied is to make the link-output appear as 50 ohms reactance to the load at the frequency in use. The rotatable link does not satisfy this condition as designed, so it is necessary to include a circuit variable which will. Obviously, another approach to the problem would be to remove the link coil, calculate the proper inductance to provide 50 ohms reactance and re-wire the link. However, the removal of this coil seemed to be considerably more of a mechanical problem than the construction of the circuit of **Fig. 4**. In addition, this method offers much more flexibility.

Audio modifications

Most amateurs prefer to use ceramic or crystal type microphones rather than suffer with the poor quality and mechanical problems associated with carbon mikes. Thus it behooves one to add pre-amplification to the audio stage in order to realize sufficient modulation percentage as compared to carrier power.

In summary, after these modifications are complete, you have an efficient, compact, low-power transmitter capable of continuous tuning from 1.5 to 12 MHz. Aside from covering the obvious amateur bands, most of the major MARS frequencies are available, particularly those of Navy MARS which are impossible with most ordinary ham equipment. Ideas will occur to many of you, which I have overlooked, because each of us have different uses for the little rig and diverse systems into which it must blend. This is what makes surplus modification so interesting. . . . K3UUL

A $4 Compressor/Preamplifier

John J. Schultz, W2EEY/1
40 Rossie Street
Mystic, Conn. 06355

By the addition of a few extra components to an inexpensive, already assembled transistor audio amplifier, one can produce a very satisfactory but yet inexpensive audio compressor for use between almost any microphone and AM or SSB transmitter.

The author has constructed many different types of audio compressors and has become convinced that under poor signal conditions and with transmitters lacking effective alc, that they are a definite advantage. The problem in constructing a compressor is that either one must start from scratch, assembling all the necessary components, or search out some piece of equipment to modify. The latter course has been used by the author using a high quality phono preamplifier. However, it certainly was not the cheapest way to proceed although the results were very good.

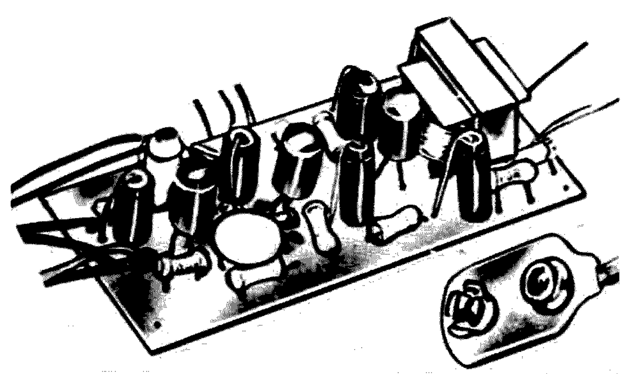
Therefore, the idea came to mind to try to modify one of the small, preassembled 100 to 200 mw audio amplifiers which are readily available at prices from $2 to $4. These imported audio amplifiers were built for use in inexpensive battery-type tape recorders and typically contain 3 or 4 transistor stages with a medium to high impedance input and a transformer coupled output to match a 4-8 ohm speaker. The results that were obtained after such a unit has been modified were indeed surprising. Distortion was quite low—at least in the 300 to 3,000 cycle range—and the compression range of about 14 to 20 db equalled that of many more expensive designs.

Only a handful of components is necessary to effect the change of the amplifier into an effective compressor and they can be readily purchased or are probably even available in most "junk box" collections. The conversion described for the amplifier used by the author is typical and can be applied to any generally similar unit.

Circuit modification

Fig. 1 shows the original diagram of the audio amplifier used, a Lafayette model 99-9039 100 mw output model. To provide compressor action some method had to be used which would allow control of the gain of the amplifier so that it would decrease automatically as the input signal level increased. There are many ways to perform this function.

Fig. 2(A) shows a very simple and effective means employing an absolute minimum of added components. In this circuit, part of the output of the 2SB176 stage is rectified by the IN270 diode. This voltage is used to bias the other IN270 diode which is connected in the microphone lead after the 47 K ohm resistor. Increased amplifier output causes the IN270 in the input circuit to be biased so it presents a low resistance to ground. In conjunction with the 47 K ohm resistor it then forms a voltage divider



Typical small 3 stage audio amplifier. Additional components for compressor control circuit are easily mounted on underside of printed circuit board. Entire assembly may be placed inside transmitter or a small minibox.

network which reduces the input signal feed to the base of the first 2SB113 stage. The value of the 47 K ohm resistor can be varied to provide the desired compressor action and also to work best with a particular microphone. The only disadvantage to this scheme is that compression action starts almost immediately on the input signal rather than at some preset "threshold" level.

This disadvantage can be overcome by the only slightly more complicated circuit of **Fig. 2(B)**. In addition, this modification introduces some degeneration which helps to improve the frequency response and lower the distortion of the amplifier. The operation is somewhat similar to the previous circuit in that two IN270 diodes are used to rectify part of the output from the collector circuit of the 2SB176 and used to control the resistance of another IN270 diode. The latter diode is connected in series with the emitter bypass capacitor of the input 2SB113 stage. In addition, there is a "threshold" biasing circuit consisting of the 100 K ohm and 25 K ohm resistors connected to the diode. Increasing output from the 2SB176 stage causes a rectified voltage to be developed which acts to back-bias the diode in the 2SB113 stage emitter circuit and thus nullify the action of the emitter bypass capacitor and reduce the stage gain. This action cannot, however, take place before the rectified control voltage exceeds the "threshold" control voltage developed across the control diode by the 100 K ohm and 25 K ohm resistors. Thus, compression action is "delayed" for very low level input signals and the amplifier essentially operates at full gain for these signals.

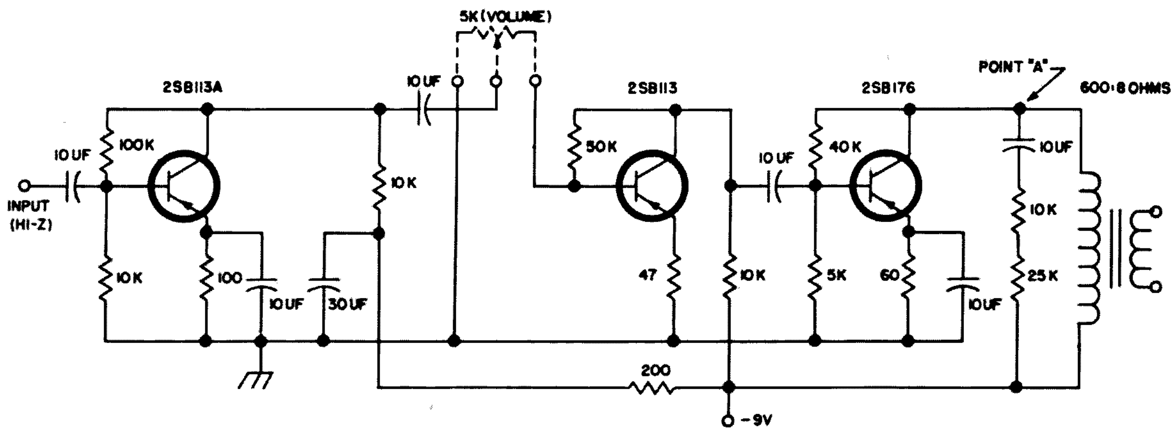


Fig. 1. Schematic of Lafayette 99-9039 *amplifier before conversion. Unit is similar to many inexpensive* 100 *to* 300 *MW class amplifiers available on market.*

A further refinement which is not absolutely necessary but which does provide an additional degree of convenience is to replace the gain control shown in **Fig. 1** with a fixed value resistor and place a 1 to 5 K ohm potentiometer in the emitter circuit of the input 2SB113 stage (in series with the 100 ohm resistor). The potentiometer will then function as a compression control with the amplifier acting as a straight preamplifier without compression action for large

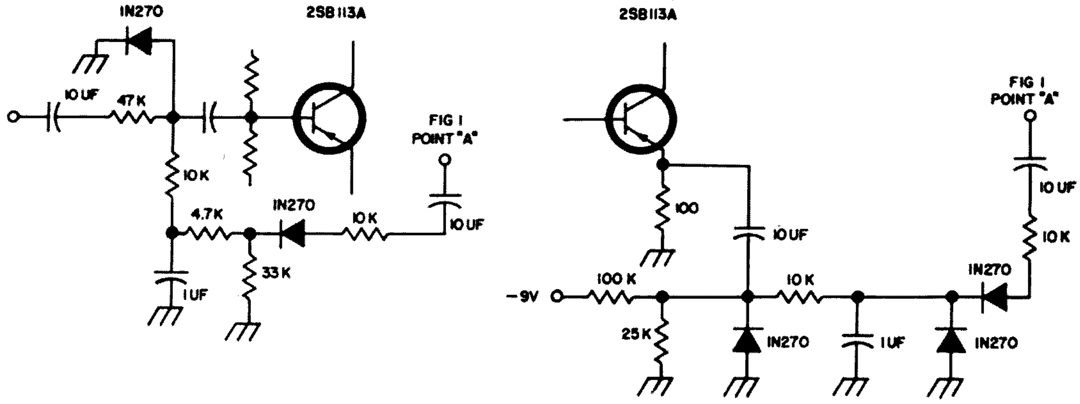

Fig. 2. Simple compressor control circuit (A) and slightly more elaborate circuit (B) providing "threshold" action.

resistance settings of the potentiometer and increasingly as a compression amplifier as the potentiometer resistance is decreased.

In the unit used by the author, output coupling for the IN270 rectifiers could simply be taken from the single-ended 2SB176 stage using the components already available as a frequency compensating network across the output transformer. Using units with push-pull output stages, a similar coupling network consisting of a 10 mF capacitor and 10 K ohm resistor in series coupled to *either* collector lead of the output stage should suffice. The output side of the output transformer is designed to operate into a low impedance load. To operate it into a high impedance microphone input on a transmitter, it will usually suffice to just place a 47 K ohm resistor in series with the output winding. The power available at the output is considerably reduced by this method but this is normally of no consequence for the usual high-gain transmitter microphone input. Otherwise, a matching transformer can, of course, be used to effect a more conventional impedance stepup.

Construction

The addition of the few additional parts necessary to turn the amplifier into a compressor can easily be accomodated on the printed circuit board of the amplifier. No particular placement of the components is necessary and if one takes a careful look at the layout of the printed circuit board, it will usually be found that almost all of the additional components can be placed on the underside of the PC board. Where tie points are necessary, a small hole can be drilled in a clear area on the PC board.

Most of the amplifier circuits are designed to be operated from 9 volt transistor batteries. A rectifier circuit can, of course, be constructed to power the unit as a compressor but usually it will be found to be far simpler to operate them from a battery supply. Since no power output is demanded from the amplifier circuit, the battery drain will only be a few milliamperes under normal operating conditions. Otherwise, if a power supply is used particular attention must be given to adequate hum filtering. The power supply should have an output capacity of 1000 mF as a minimum.

Operation

There are many ways to evaluate the performance of a compressor unit. On the air tests are only useful if they are conducted under weak-signal conditions or properly simulated weak-signal conditions. The latter is sometimes difficult to do on a local contact unless both parties in the QSO understand what objective is being attempted with the compressor. That objective, of course, is to raise the average power output of a transmitter. Thus, if tests are conducted under strong signal conditions with full rf gain control setting on the receiver being used to check the transmission, little or no variation in signal strength may be observed with the compressor in or out of the transmitter. This is because the receiver agc "washes out" the variations in received signal strength as heard aurally. Such a test should be made with the lc gain control on the receiver reduced to the minimum which will allow reception without the compressor used in the transmitter. When the compressor is inserted, a more accurate demonstration of its effect will then be obtained.

In some cases, the effect of using the compressor is readily observed at the transmitter. For instance, in the author's situation an HA-14 linear is used. The plates of the 572 tubes normally appear gray under operation without the compressor. Using the compressor, the plates develop a dull red color. This is due to increased average power input which certainly—assuming no audio distortion—means increased signal strength being radiated.

The increase in average power is difficult to determine exactly without complex instrumentation, but it seems to be in the order of 20 to 30 percent. This may not appear tremendous but, considering that only 4 dollars was invested, there would hardly seem to be any easier way to squeeze a bit of additional power from an existing linear.

The ways shown in this article to convert an inexpensive amplifier into a compressor are certainly not the only methods usable. A multitude of articles have used other methods. However, with a bit of care they can all be adapted to use an inexpensive amplifier as described in this article as a foundation since only the control circircuits are different but the basic amplifier stages remain the same. . . . Reactance or Impedance?

A problem encountered by technical people for many years involves the two fleeting quantities known as impedance and reactance. One never really knows when reading an article or text which one is being discussed due to the ambiguity traditionally associated with these terms. Many publications presently in print speak freely of reactance as having a "phase angle", or impedance as being a simple number quantity. Both of these statements are totally incorrect.

Reactance is a term applied to a quantity having magnitude only with no regard to direction. Impedance, on the other hand, not only implies magnitude, but dictates a particular direction as well. The reactance of an inductor of 1 Henry being operated at a frequency of 60 Hz would be:

$$X_L = 2\pi fL = 2\pi(60)(1) = 377 \text{ ohms}$$

This quantity is called reactance and has a value of 377 ohms, with no consideration given as to direction. If at this point we say that our inductor has a value of 377 ohms at angle (direction) of 90 degrees, we have immediately bridged the gap and developed a new quantity called *impedance*.

Consider the following analogy: A bullet is fired from a rifle at a speed of 600 miles per hour. Only one correct deduction concerning the bullet may be made with the information given; namely, that it is moving fast enough to do physical harm. It would behoove those concerned to also know the direction of travel to avoid an early demise. In other words, the information conveyed by knowing both the magnitude and the direction is most beneficial. The same is true with reactance and impedance. Reactance conveys magnitude information only; impedance denotes magnitude and direction.

In order to manipulate these quantities from a mathematical standpoint, the concept of Complex Notation must be introduced. It should be immediately pointed out that the only thing complex about complex numbers is the name. This is mentioned to overcome mental blocks, which usually arise during the initial stages of development.

A complex number is represented by the sum of two numbers, one called the real part, and the other called an imaginary part. Since both real numbers and imaginary numbers are simply numbers which we use daily (1, 2, 3.9, 2.7, 19, 140.2, etc.), we must somehow distinguish between the two. In order to do this, we introduce the imaginary operator j, which acts as an indicator much the same as a flagman would in traffic. As an example, let us assume we have the complex number: $A = 3 + j4$. In this case, the real part of the complex number A is 3; while the imaginary part is 4. Note that the function of j is only to indicate that there is something "different" about the number 4.

Relating this concept to the realm of impedance, we note that, in general, impedance is also a complex quantity. The real part of impedance is called resistance denoted by the letter R. The imaginary part of impedance is called reactance and is symbolized by the letter X.

Let us now consider a circuit containing only an ideal inductor.

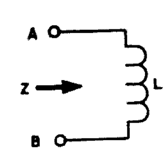

Fig. 1. A very simple inductive circuit. If the resistance is zero the voltage leads the current by 90 degrees and we say $Z = 0 + jX_L$ ohms.

It is the object now to determine the total circuit impedance looking into terminals AB. In the circuit shown there is no resistance (R), therefore, there is no real part in our complex number. The imaginary part of the impedance is the inductive reactance X_L. X_L may be found knowing the inductance (L), and the frequency (f) as was shown in a previous example. The total impedance is:

$Z = 0 + j\,X_L$ ohms, where j indicates the direction.

Since this quantity possesses both magnitude and direction, it is often more easily understood when illustrated graphically on a standard Cartesian Coordinate System. Our real axis is along the horizontal, while our imaginary is plotted vertically. By convention, always plot the real part first and then plot the imaginary in a tip to tail fashion, utilizing the previous example, plotting resistance first $R = 0$. Now add the imaginary portion to the real obtaining the value X_L plotted vertically on the imaginary axis.

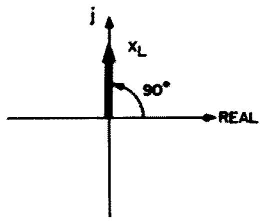

Fig. 2. Here we are saying $Z = 0 + jX_L$ ohms, graphically. The heavy arrow represents impedance. Its length indicates the value of the impedance, which we call reactance.

We will pick the horizontal axis to the right as being positive. All positive angles are measured with respect to this axis when moving in a counterclockwise direction. Returning to our example and measuring this angle with a protractor, we see it to be a positive 90°. The significance of this angle will be discussed later.

As a second example, consider a capacitor only, the impedance of which is to be determined. The reactance of the capacitor is given by:

$$X_C = \frac{1}{\omega C}$$

Now by definition we choose the capacitive impedance to have a $-j$ associated with it. Therefore, the capacitive impedance becomes $-jX_C$, and it is plotted on the graph previously mentioned, vertically downward as shown below:

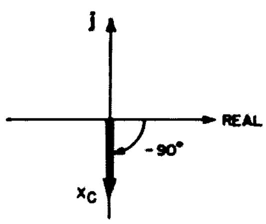

Fig. 3. If we replace the inductor of Fig. 1 with a capacitor, still assuming there is no resistance, the impedance arrow now points downward.

It can be seen by these brief examples that the j designation for the impedances save confusion when writing the values.

Let us now consider a combination of an R, L, C connected in series. It will be our objective to calculate the total impedance in both mathematical forms. Given the circuit in **Fig. 4:**

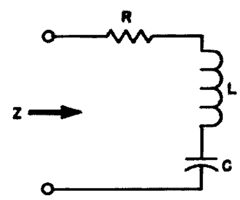

Fig. 4. Here is a more complex circuit. We might find this in a bandwidth-limiting application. What is its impedance?

The reactances of each of the components may be found by the usual manner, X_L and X_C. We will now determine the values of the individual impedances. The impedance of the resistance is the easiest, for it consists of a real part only, that is, $Z_R = R + j0$ ohms. The impedance of the capacitor is $Z_C = 0 - jX_C$ ohms, and for the inductor it is equal to $Z_L = 0 + jX_L$ ohms. Impedance in series add and, therefore, the total impedance is $Z_R + Z_C + Z_L = Z_T$ or $Z_T = R + j0 + 0 + jX_L + 0 - jX_C$ ohms. We can find the sum by adding the real parts and the imaginary parts separately. $Z_T = R + jX_L - jX_C$, but since the j term is common in this case, Z_T becomes $Z_T = R + j\,(X_L - X_C)$. This can be shown graphically by the following:

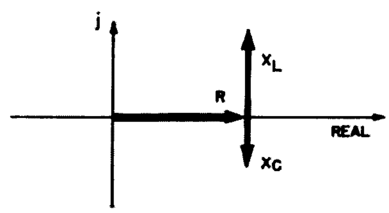

Fig. 5. First we must know the frequency. Then we determine impedance by adding resistance and reactance values graphically, or by math having the same meaning. Remember reactance will vary with frequency, changing the impedance.

Note that R was plotted first, then jX_L and $-jX_C$ in the tip to tail fashion described previously. jX_L and $-jX_C$ lie in the same plane, however, in the opposite direction. Therefore, the result of $j\,(X_L - X_C)$ can be found by algebraically subtracting X_C from X_L. The result X_T remains unchanged but X_T is now in the positive direction, this is because X_L is larger than X_C in this example.

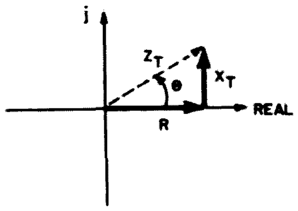

Fig. 6. Taking the difference between inductive and capacitive reactance, the inductive reactance wins this time. At some lower frequency they would cancel, leaving resistance only. And at a still lower frequency the capacitive reactance would predominate.

If the other case were true (X_L smaller than X_C), the result X_T would point in the negative direction. X_T and R form a right triangle and the line Z_T represents the hypotenuse of the right triangle. Using the theorem developed by Pythagorus which says that the hypotenuse of a right triangle is equal to the square root of the sum of the other two sides squared, the magnitude of Z_T becomes:

$$|Z_T| = \sqrt{R^2 + X^2} \text{ ohms}$$

which is the formula given in most handbooks. However, this is only half the picture; we still must have a direction. The angle θ on Fig. 6 can be found by the formula:

$$\theta = \arctan \frac{X_T}{R}$$

Read, theta is the angle whose tangent is $\frac{X_T}{R}$. Therefore, the impedance may be expressed in two ways:

$$Z = R + j\ (Z_L - X_C) \text{ or } Z_T \angle\theta$$

To summarize, let us now turn our attention to a numerical example. Consider an R, L, C series circuit being used at 60 Hz. The value of the individual components are as follows: R = 300 ohms, L = 0.5 Henrys and C = 10 microfarads.

Calculating the reactances:

$$X_L = 2\pi fL = 2\pi\ (60)\ (0.5)$$
$$X_L = 188.5 \text{ ohms}$$
$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(60)(1\text{x}10^{-6})}$$
$$X_C = 265.0 \text{ ohms}$$
$$Z = 300. + j\ (188.5 - 265.)\text{ ohms}$$
or $$Z = 300. - j\ 76.5 \text{ ohms}$$

See **Fig 7** for graphic illustration.

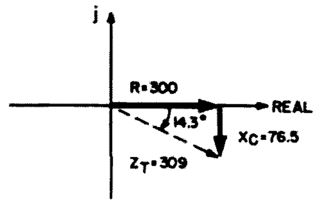

Fig. 7. Working out the circuit of Fig. 4. If we apply a 60 Hz current to this circuit we will find the voltage across its terminals lagging 14.3 degrees. Or if we trigger our scope from the voltage signal the current will appear to lead by the same 14.3 degrees.

$$Z_T = \sqrt{(300)^2 + (76.5)^2} = 309 \text{ ohms}$$

$$\theta = \arctan \frac{-76.5}{300} = -14.3 \text{ degrees}$$

The total impedance for this circuit is 309 ohms at an angle of −14.3 degrees.

The angle associated with the impedance in actuality represents an angular (phase) difference between the voltage applied to, and the current in the circuit considered. By definition, if the angle associated with the impedance is positive the voltage leads the current, and the circuit appears basically inductive. Similarly, if the angle is negative, as in the previous sample, the current leads the voltage, and the circuit appears to be predominantly capacitive. The special case of no phase shift occurring between voltage and current, (corresponding to an angle of zero degrees) simply indicates a purely resistive circuit.

On can at this point begin to appreciate the significance of the quantity impedance, and the enormous amount of information conveyed with it, as opposed to the simple quantity reactance.

Whether engineer, technician, serviceman or home experimenter, the blossoming age of electrical technology demands an understanding of the subtle distinction between these two very basic circuit concepts.

Of all the surplus receivers available, probably the easiest to come by, and most neglected, are the ac-dc broadcast receivers. They are not the most sophisticated, but certainly they are reliable. These receivers will give years of service.

Here is a conversion project that should take under a half hour, and give hours of listening pleasure. The conversion will give you a low, fixed frequency weather monitor receiver. The Federal Aviation Administration broadcasts reports for fliers, usually start at 5:00 A.M. and continue untill 11:00 P.M. There is a projected weather report and a current report that is changed hourly. Pick the weather station nearest to you from the list. You will hear the identification in MCW, below the verbal report.

Step 1. First, be sure the receiver is receiving the broadcast band normally.

Step 2. Disconnect the receiver from the ac source and remove the chassis from the case.

Step 3. Turn the variable capacitor to maximum capacitance (fully meshed) then solder the shaft to the frame, thus locking the variable capacitor. Use at least a 100 watt soldering iron.

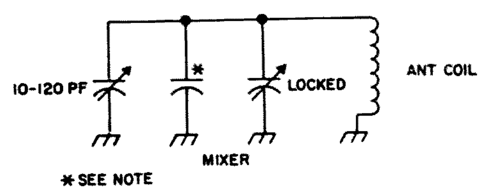
Step 4. Solder a variable capacitor, 10-120 PF, across the oscillator section. The oscillator section can be identified by the fact that it has the least number of plates. Solder the ground side of the capacitor to the frame of the original capacitor. The other terminal goes to the tab of the oscillator capacitor.

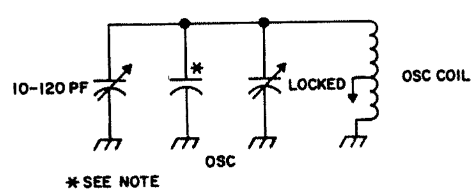
Step 5. Connect a fixed 300 pF* capacitor, plus a 10-120 pF variable across the converter section of the original capacitor. One side of the fixed and variable capacitors is soldered to the frame, the other sides are connected to the tab of the original capacitor. Connect a 10 mF 25-volt capacitor across the cathode resistor of the last stage of audio.

Step 6. Remember, all ac-dc receivers are dangerous to the point of being lethal when removed from their insulated cases. If you have an isolation transformer, now is the time for it; if not, check the polarity of the 115-volt plug, so that the chassis is not on the high side of the ac line (I would hate to lose you at this stage).

Step 7. Now with the set turned on, and the volume up, with an insulated tool, tune the variable oscillator capacitor until you hear the weather station. Now tune the converter variable capacitor for the loudest point.

Step 8. Remove ac power source. Install the chassis in case, be sure to use the original insulated knobs.





Note:
*For weather stations down to 350 kHz, use 300 pF capacitor across mixer capacitor.
For weather stations down to 295 kHz, use 650 pF capacitor across mixer capacitor.
For weather stations down to 220 kHz, use 1,400 pF capacitor, and in addition, use a 100 pF capacitor across oscillator capacitor at this low frequency.

Photos by Les Toth

Step 9. Conversion is now complete, and the receiver is as safe as it ever was.

True, we can do very little to change the weather, but at least we can keep informed and know what to do to prepare for it. ■

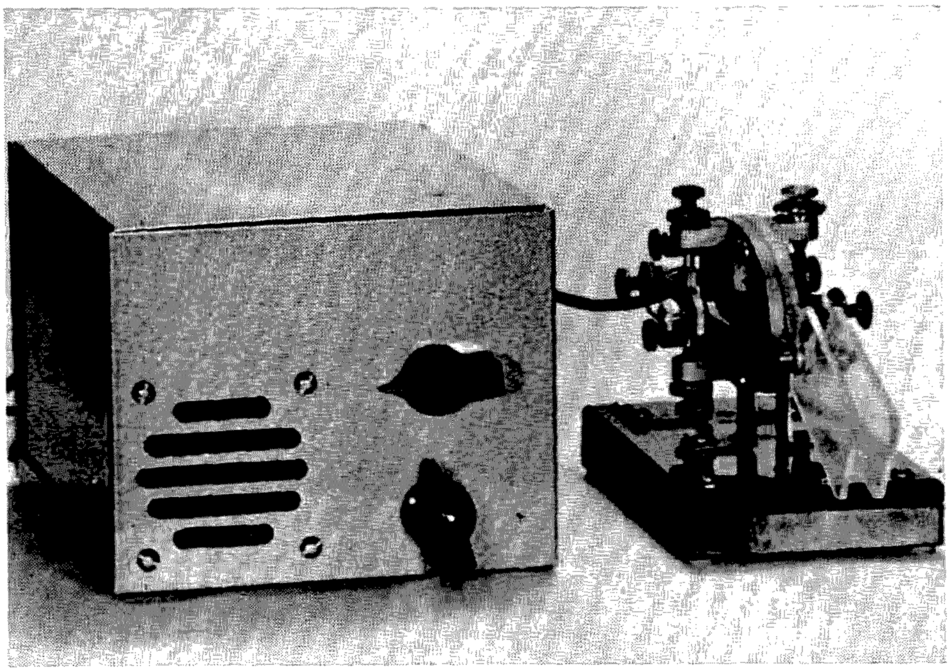
The Charmin' Keyer

Richard Schwanke W9HXM
235 Cumnor Avenue
Glen Ellyn, Illinois



Nowadays, if on operates CW without a squeeze keyer, he is not a member of the *in* group. The squeeze keyer presented here is, to the best of the author's knowledge, the first unit which will perform either of the two popular forms of squeeze keying.[1,2] When desired, it can be used as a conventional keyer. With a single lever, it has very agreeable timing and is rather forgiving of operator errors.

The circuit diagrams are presented. **Fig. 1** is drawn with NPN transistors and will be used in all of the rest of the article for discussion of logic. **Fig. 13** is drawn with PNP transistors for those with a large supply of PNPs and for those who would like to modernize a keyer circuit published in 1962[3] which has many of the same components.

It would have been much easier to design this keyer with integrated circuits, but the cost to noise margin ratio is much more favorable in the discrete component version.

1. Gensler, Harry, Jr., "The Iambimatic Concept," QST, Jan., 1967.
2. Moss, Jimmy, "The WØEPV Squeeze Keyer," QST, July, 1967.
3. Muir, Dave, "The Penultimate Electronic Key," QST, March, 1962.

Brief description

Fundamentally, this keyer consists of a dot generator with a binary counter which is used to fill in the spaces between two dots to form a dash. Several control paths are used. One path (R_{50}) controls the dot generator directly and combines with feedback from the output of the dot generator (R_{51}, D_{12}) giving self completion. A second path (R_9, D_2) sets the Dash FF enabling the binary counter via R_{43}. A reset signal is provided to the Dash FF via C_2, D_4 every time the relay opens. A third path (R_{53}, Q_{13}) sets the Dot FF if and only if the Dash FF is set. A fourth path (D_5, D_6, R_{21}) allows the Dot FF to be rest if and only if the Dash FF is NOT set thus providing Dot Memory. A fifth path (Q_{14}, R_9, D_1 R_{10}) prevents setting the Dash FF if the Dot FF is set or a dot is in progress. A sixth path (R_{18}, R_{24}) keeps the Dot Generator running when either the Dot FF or the Dash FF is set.

The final result of these controls gives a keyer which can remember one dot that was called for during a dash with no critical timing and will either give alternate dots and dashes when both dot and dash

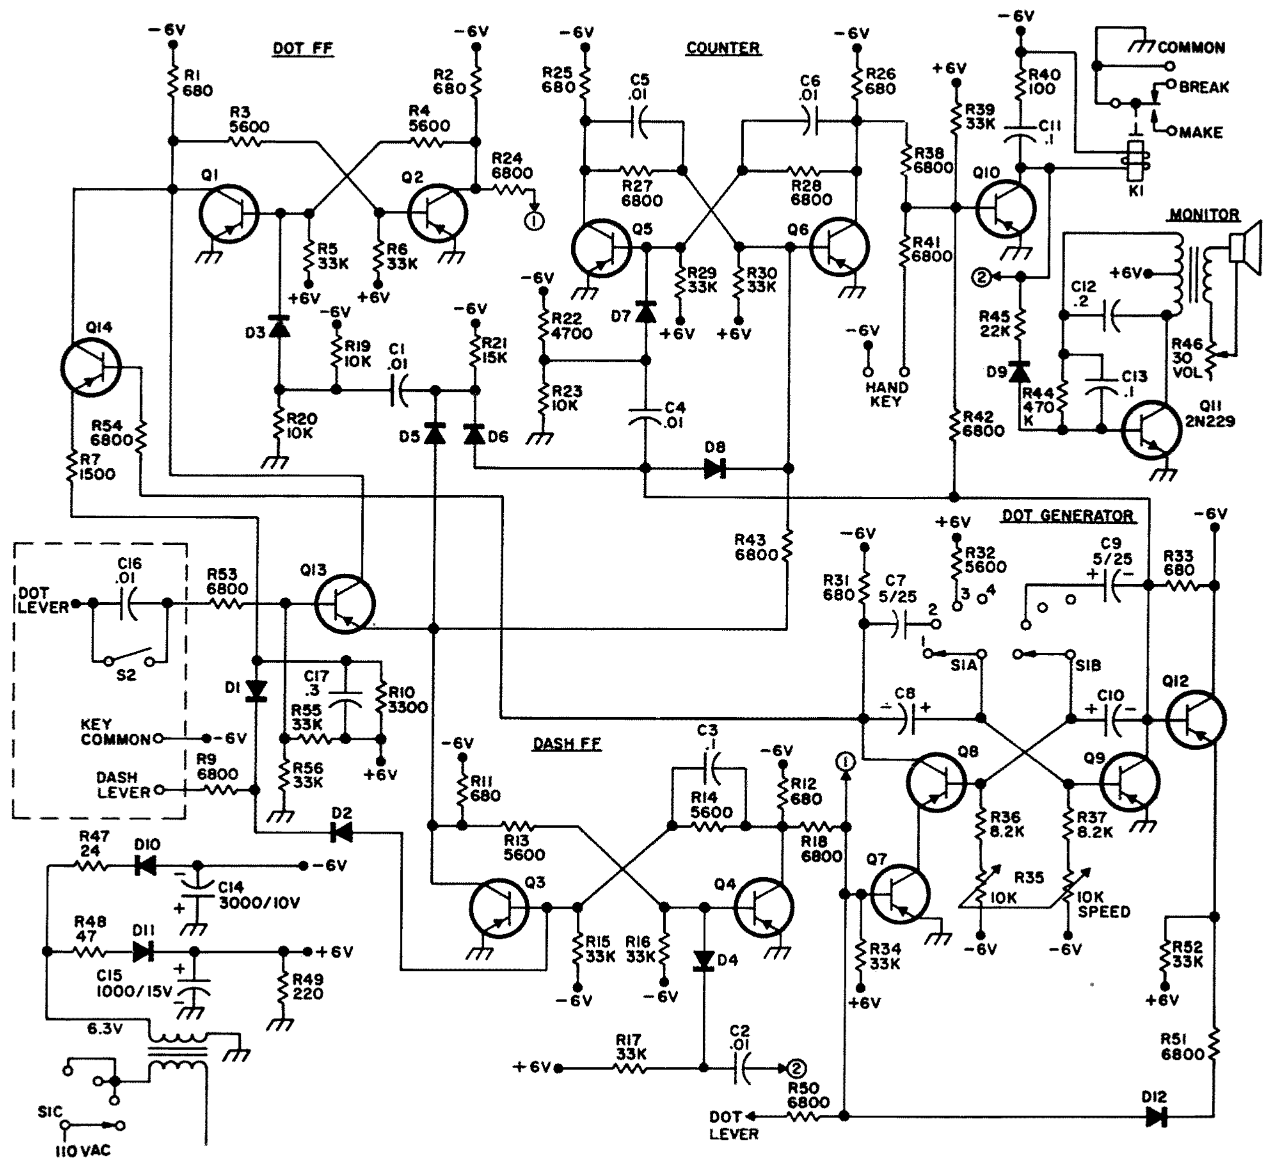


Fig. 1. Complete circuit using NPN transistors. K_1—500 ohm relay. Q_1-Q_{10}, Q_{12}-Q_{14}—NPN (2N2923). *Q_{15}—PNP* (2N4126). *D_1-8—Germanium* 1N90. *D_9—Silicon. D_{10}-$_{11}$—Silicon* 50 *PIV*, 100 *mA. S_1*—3 *pole* 4 *pos. rotary switch* (*Mallory* 3134*J*). *S_2—SPST.*

levers are held or insert one dot in a string of dashes. The use of two independent key levers which may be squeezed to produce additional combinations is required to realize all of the potential benefits.

When switch S2 is closed, a squeeze will produce a continuous string of alternating dots and dashes thus making characters such as C and AR almost effortless. The timing required by the operator is very uncritical and one need only follow the instructions on the chart (**Fig. 2a**) supplied to learn the new technique in one or two evenings.

If switch S2 is opened, the operator will feel as though he has an entirely different keyer and a chart (**Fig. 2b**) shows the details of the second technique which the author calls single dot insertion (SDI). With SDI, one and only one dot will be produced during any single squeeze.

Alert readers (and those who have already studied the charts) have figured out that one set of characters is very easy with the alternating option, and an entirely different group is very easy with the SDI option. It is believed that this is the first

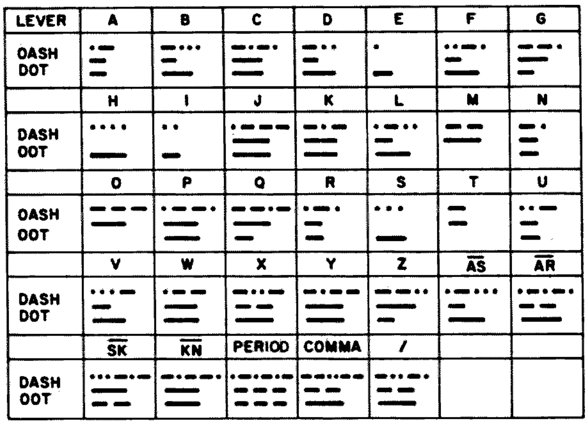

Fig. 2A. Keying chart (S2 closed). Alternate dots and dashes with dot memory.

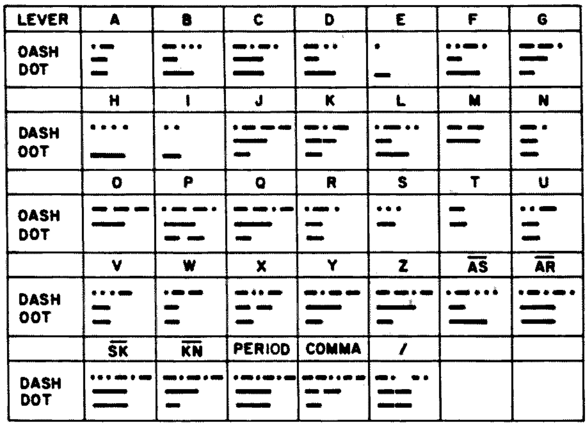

Fig. 2B. (S2 open) Single dot insertion.

published design where the operator can try both methods and make an intelligent choice after he has spent his money instead of tossing a coin beforehand and later being sorry. He can even change his mind years later at no additional cost.

Numerals are not listed in the charts as they are merely extensions of J, V, B, and G. The keyer will operate in the conventional way with a single lever while retaining the advantages of DOT MEMORY.

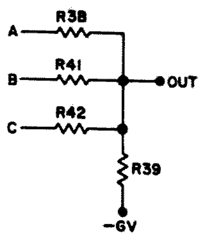

Fig. 3. Resistor OR circuit.

Theory of operation

The circuit presented here, while somewhat complicated in appearance, is a collection of basic logic circuits each consisting of a small number of elements. In **Fig. 3,** a resistor OR circuit is shown. If any of the inputs (A, B, or C) is UP (True), then the output is UP. If all of the inputs are DOWN (False), then the output is DOWN. Nothing more complicated than a voltage divider with low resistance input resistors and a high value bias resistor is needed to accomplish this function. The resistor OR is used to turn on the clock and for combining the clock and binary counter in the base of the relay driver.

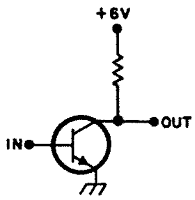

Fig. 4. Transistor inverter.

Fig. 4 is a transistor inverter of which there are ten used in this keyer. When the input is UP, current flows in the base-emitter junction causing a much larger current to flow in the collector-emitter junction and thus through the collector load resistor. The amplification of current is important and must not be forgotten, but the most important point in this discussion is that when the input is UP, the output is DOWN, Thus inverting the signal. This is commonly referred to as the NOT function. Combining the resistor OR with the transistor NOT forms a logic block called a NOR circuit which will not be treated further here.

When the output of one Inverter in **Fig. 5** is used as the input to a second Inverter and the output of the second is used as the input to the first, a FLIP-FLOP is formed. A FLIP-FLOP can be thought of as a teeter-totter, a long board with its center of gravity somewhat above its pivot point such that it will stay on one side or the other but is unstable in the transition. The FLIP-FLOP is also called a bistable multivibrator and is used for temporary memory. For example the DOT FF remembers a dot to be generated and the DASH FF remembers a dash is in progress.

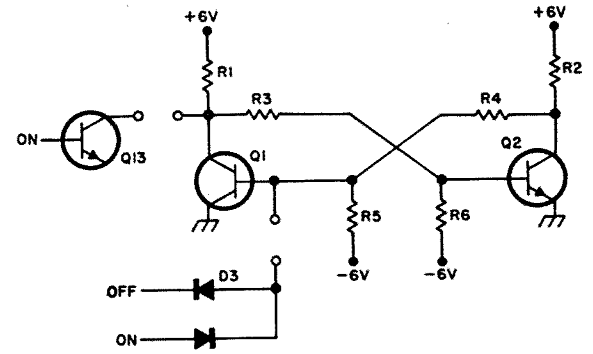

Fig. 5. Bistable Multi-Vibrator Flip-Flop.

A FLIP-FLOP can be made to change states by 1) pulling down on the collector of the off or UP side (Q_{13}), 2) forcing the off transistor on at its base (R_{43} and R_9, D_2), or 3) forcing the on transistor off at its base (D_3). Emitter triggering is not used here.

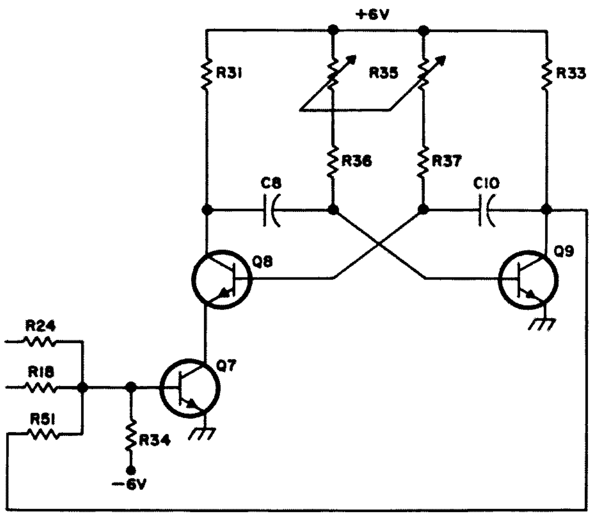

Fig. 6. Astable Multivibrator

The astable multivibrator in **Fig. 6** is similar to the FLIP-FLOP except for the feedback paths which are primarily (or in this case entirely) ac instead of dc. The astable multivibrator will change quickly from one side to the other and remain as long as the charge on a coupling capacitor holds one transistor off. When this charge finally bleeds to a small enough value, the OFF transistor will turn on and, through the other coupling capacitor, force the formerly ON transistor off. The result is a regular oscillation which is square wave in nature. Observation in an oscilloscope (**Fig. 7**) shows that the transition from UP to DOWN is much faster than the transition from DOWN to UP and is more useful for forming pulses.

Fig. 7. Waveform at Collector or Astable Multivibrator.

In this circuit, as astable multivibrator is used as the main clock and DOT generator. Such an oscillator may be turned on and off with predictable results by inserting a transistor inverter (Q_7) between one emitter and ground thus serving as a switch. Once started, completion of one cycle can be guaranteed by using the output of the oscillator (with proper polarity) as one of the inputs to the OR gate controlling the switch (Q_7).

When loading becomes a problem, it is sometimes necessary to use an emitter follower which will enable driving many more circuits than a FLIP-FLOP alone or an oscillator alone can handle. This device is used on the oscillator (Q_{12} in **Fig. 1**).

Pulses can be obtained from a square wave by differentiating in an RC network where the pulses can be given a suitable dc base line by choice of voltages and resistors as shown in **Fig. 8.** The positive or negative going pulses may be selected by means of diodes. Time can be changed one half cycle by using the other side of the oscillator. Pulses from the oscillator are used to trigger the binary counter and, with suitable gating, reset the DOT FF.

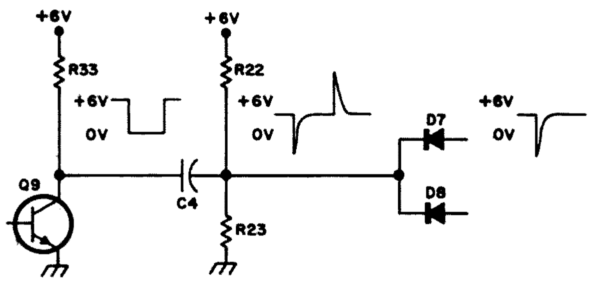

Fig. 8. Pulse formation and selection from a square wave.

A two transistor AND circuit with inverted output is shown in **Fig. 9.** This is commonly called a NAND logic block. When the inputs to both transistors are UP, the output is DOWN thus setting the DOT FLIP-FLOP shown in **Fig. 1** since R_1 is common to both circuits. The DOT **FF** is set if and only if the DASH FF is set.

There is one other feature worth noting here. All FLIP-FLOPS (or multivibrators) have two outputs. When one of these is

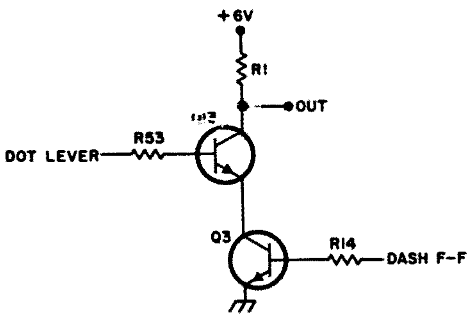

Fig. 9. Transistor NAND.

arbitrarily called True (UP) then the other output must be False (DOWN) and is referred to as the complement of the chosen output. A bar over the signal name is the usual notation for the complement of a signal.

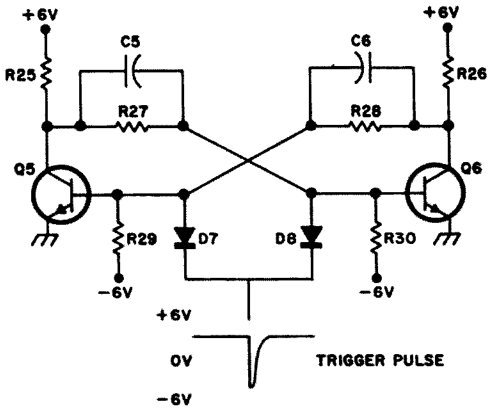

Fig. 10. Binary Counter.

Fig. 10 shows a FLIP-FLOP with steering diodes added such that it will operate as a binary counter by changing state every time a pulse comes along. The pulse duration, amplitude and polarity are selected so that whichever transistor is ON will be turned off. (Obviously the transistor which is OFF will not be affected by this pulse). As the ON transistor is turning off, the voltage at the collector rises rapidly so that a new pulse is ac coupled to the base of the OFF transistor thus turning it on. Due to the rc constants used and the delay between the first and second pulse, the second pulse will be larger than the first and will be definitely in control when it arrives. The binary counter fills in the spaces between the dots when combined with the clock in an OR gate, thus forming a dash.

One very unusual device used in this circuit is the inductive kick which occurs whenever the current flowing through an inductance such as a relay coil is stopped suddenly. **Fig. 11** shows the circuit and the voltages seen at three points in the circuit. This pulse is used to reset the dash FLIP-FLOP.

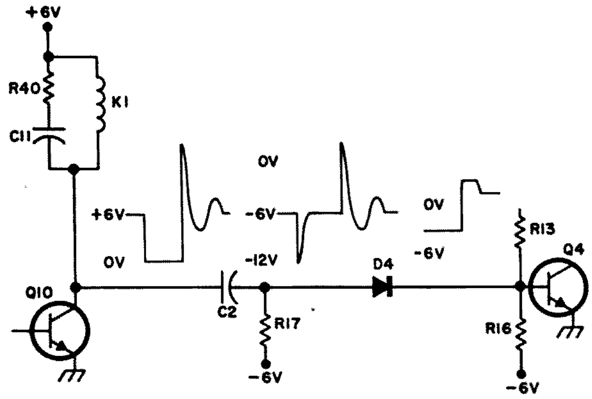

Fig. 11. Waveforms in Dash F-F reset circuit.

It is necessary that the DASH FF can not be set any time a dot is in progress or being remembered. **Fig. 12** shows the solution. Q_{14} and R_{54} form an OR gate with negative logic. Only when A and B are both UP can an UP at Dash turn on Q_3 If either A OR B are DOWN the DASH signal goes through D_1 and R_{10} to —6V and Q_3 is unaffected. D_1 and D_2 form an AND gate.

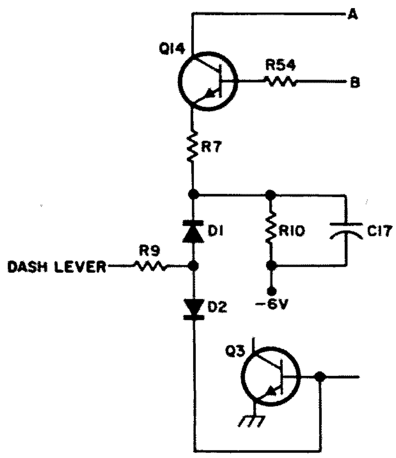

Fig. 12. Dash F-F-Set circuit.

Components

The circuit design presented here is not tied to any particular transistor number or category. The chances are very good that

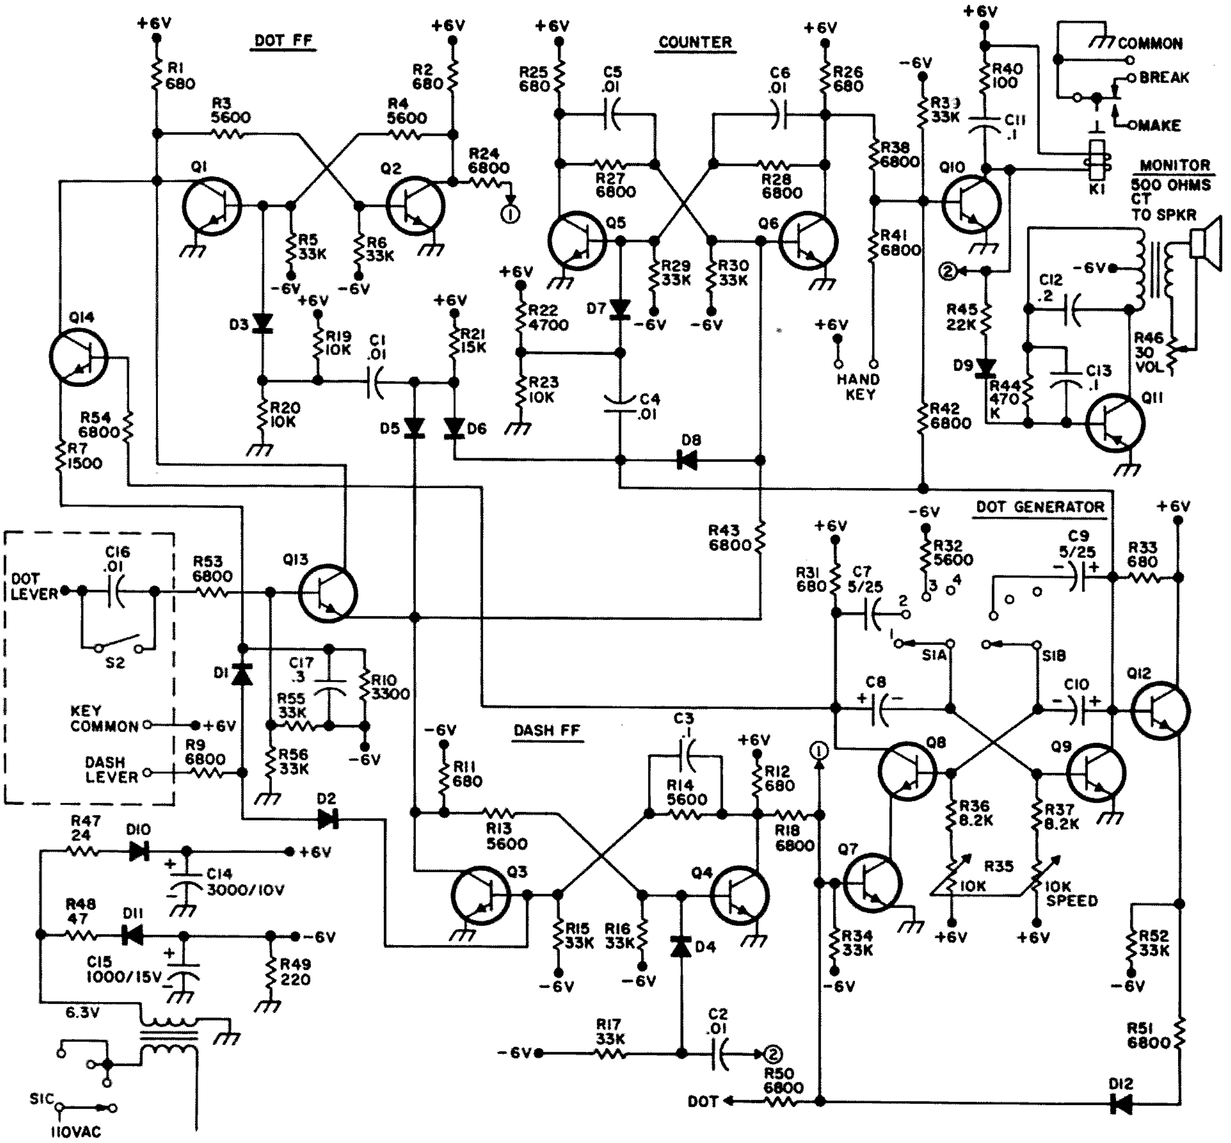

Fig. 13. Complete circuit using PNP transistors. All parts values same as Fig. 1. except $Q_{1\text{-}10}$, $Q_{12\text{-}14}$ are PNP (2N363), and Q_{11} is NPN (2N227).

components removed from old computer circuit cards can be substituted directly. Even though the voltages were different and the collector load resistors and base resistors are different, the chances are excellent that they can be used. However, it is a good idea to observe the relationship of the collector load resistors to the base resistors and the back biasing resistors in **Fig. 1** and not depart widely from these ratios.

There are a couple of areas where trouble can occur. Old germanium transistors have a tendency to get just a little bit sick, and thus erratic, but not sick enough so that they can be spotted easily. If you plan to use anything doubtful, it is a good idea to install sockets so that substitution is not a chore. The inductive kick in the relay circuit is surprisingly large so that a good healthy transistor is in order here.

It is recommended that a rough check of the gain and leakage be made if nothing is known about the transistors to be used. Leakage is a measure of the collector current with several volts applied and the base open and should be almost undetectable on a 1 mA meter. Gain is only a little more difficult. Assuming a 6 volt supply, choose a 300 ohm collector load resistor so that 10 mA will give a 3 volt drop across the resistor. Now find a base resistor which will cause 10 mA to flow at the collector and calculate the base current. The ratio of collector current to base current is an approximation of gain when leakage is low and must be at least 20 (much better 40). A pair of transistors used in a flip-flop should be within 25% of each other for ultra-reliable operation although no problems have been traced to this source.

Almost any germanium signal diodes can be used. (Silicon diodes should also be useable but have not been tried.) Germanium diodes will have a forward voltage drop of about 0.3 volt with a few ma flowing while silicon diodes will have a forward drop of 0.6 volt and will usually be painted black to eliminate the photo diode effect. Check the back resistance which should be at least 200 k ohms.

A reed relay is recommended for reliable, quiet high speed operation. However, there are some more economical types which are quite reliable at speeds below 30 wpm. If the relay is a little too slow it will give short dots. This can be fixed by unbalancing the oscillator to compensate. (R_{36} or R_{37} in **Fig. 1** may be reduced to 4 k ohms for balancing purposes. Do not go below 4 k oms or excessive base current will result).

If high gain transistors are used in the oscillator, a greater speed range can be obtained with a larger valued dual potentiometer. The upper speed limit can be raised by using smaller capacitors. The components

listed will go from 5 to about 40 wpm.

The power supply voltages are not critical except that the positive and negative voltages should be nearly the same and if much different from that required by the relay, a dropping resistor may be needed somewhere to make things work out right. R_{47}, R_{48}, and R_{49} may be altered to adjust the positive and negative voltages. It is most important that power supply ripple be within reason or a phenomenon known as collector triggering will cause erratic timing in the dot generator. This is unlikely to happen with the components listed unless the electrolytic capacitors are defective.

Construction

The author has built many circuits of this type on perforated phenolic board with completely satisfactory results. The kind with closest spacing of the holes will allow a considerably smaller package. Eyelets can be very helpful if a setting tool is available, otherwise use flea clips or other push in terminals as needed.

This particular circuit has also been built on a printed circuit board which was laid out to accept a wide variety of economical components in either the PNP or NPN configuration.

Getting it to work

Before installing Q_7, use a voltmeter as an indicator with a probe on one of the collectors of a FLIP-FLOP while applying a 6.8k resistor from V_{cc} (+6V) to first one base and then the other base. The output should remain high or low depending on which transistor base was last touched. This test should be used on the DOT FF, the DASH FF and the COUNTER. Any of these that do not work should first be checked for wiring and then for components.

Next, hook up Q_7, the transistor controlling the oscillator. The output of the oscillator should be down. Now closing the dot lever should make the oscillator start. A voltmeter at the oscillator output should average half the supply voltage. An ohmmeter applied to the relay contacts should vibrate near half scale. If not, look for wiring errors or faulty parts in the relay driver. The oscillator should also operate when the dash lever is held. If not, look to see if the Dash FF is being set and if it is properly connected to the transistor controlling the oscillator. An ohmmeter connected to the relay contacts should now read about three quarter scale. If it still reads half scale, the counter is not working. Check wiring and then components. Make sure the counter is connected to the relay driver.

The dots and dashes should stop when the levers are released. If the dots fail to stop, check the emitter follower on the oscillator and the resistor and diode going to the control transistor. Also check for reseting of the Dot FF. If the dots work OK but the dashes will not stop, the most likely cause is in the components going from the collector of the relay driver to the Dash FF. Look for the diode to be in backwards or routed to the wrong base. Try changing C_2 to .02 mfd.

Now the squeeze feature can be checked. Set the keyer at its lowest speed and hold the dash lever closed. Tap the dot lever at random times. A dot should occur between two dashes each time the dot lever is tapped. If errors occur, the Dot FF is not being set. Check the wiring to the Dot FF. With S_2 closed, holding or squeezing both levers should cause alternate dots and dashes. With S_2 open, holding both levers should cause one and only one dot and a string of dashes. The specific location of the dot will be determined by the precise time the dot lever was closed in relation to the dash lever.

It is quite probable that the monitor note will be rough or the wrong frequency. Improvements can be had by experimenting with R_{44}, C_{12}, and C_{13}. If a sine wave is achieved, it will likely be accompanied by chirp which is also annoying. The monitor is a compromise as it does not contribute anything to the keyer operation and a better one would cost considerably more.

In one of the early models built with transistors of unknown quality, erratic operation was traced to low gain of Q_3 Thus it is suggested that the highest gain transistors be used at Q_8 and Q_9 while the next highest gain be used at Q_3 If new silicon transistors are used, no selection should be needed as the lowest gain likely to be supplied is more than adequate.

Conclusion

It is believed that many good circuits have fallen into disuse because they have some

minor defect when it would be quite profitable and satisfying to rework one of them to meet current requirements. The keyer presented in this article is completely new in its philosophy, logic, and timing, yet is was created from a 1962 model[3] by the deletion of one part and the addition of twelve new ones at a cost of less than three dollars.

Those who build the CHARMIN' KEYER will soon become unhappy with older keyers including some that cost twice as much and they need have no worries about operating close to a high powered linear. . . . W9HX

Amateur Radio Knows No Borders

Last fall, when Wayne Green and his wife, Lin, were vacationing in Europe, they met Fernand Dubret, HB9PJ, of Geneva, Switzerland. Mr. Dubret told them of his role as an amateur radio operator in saving the life of a Polish child who was dying of Wilm's tumor, a malignant tumor of the kidney.

Recently, Mr. Dubret sent his personal account of his arranging to send requested medication across the iron curtain. With his account were several photographs, and copies of congratulatory letters from the Polish Ambassador in Geneva, and from the International Amateur Radio Club. The material presented is based primarily upon his account.

On February 24, 1968, at 4:00 p.m. Fernard Dubret, HB9PJ, a French citizen who lives in Geneva, received a distress message on 14080 Kcls from SP3AUZ, Julius Schmidt, of Poland.

"CQ HB, CQ D, CQ G Medical SOS Mayday Please help for a dying four year old Polish child. We need within 24 hours a rare drug called Cosmegene from Firma Merck and Döhme. Please send the drug to Nowa Sol, Poland, immediately, please help."

Immediately, Mr. Dubret, who is an official with the International Telecommunications Union, responded and began to seek assistance from several doctors who were on call (some who were unfamiliar with the drug), and from several pharmacies, which were

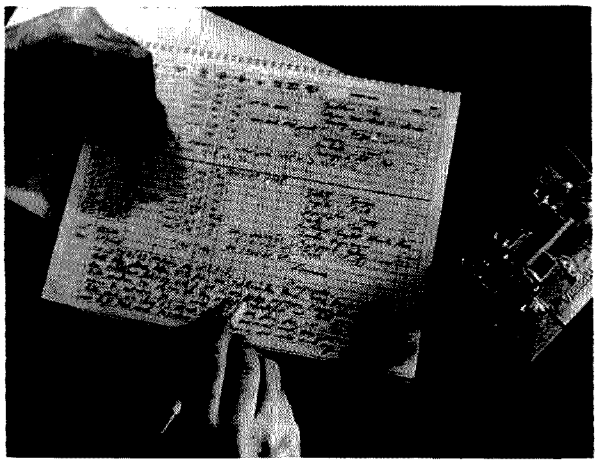

Photo of the Log at HB9PJ recording the incident.

Fernand Dubret HP9PJ. In his shack near Geneva, Switzerland.

Julek Schmidt, SP3AUZ. In Poland.

Marek in his hospital bed prior to the injection of the drug.

unable to supply the medication without a prescription. He alerted the Red Cross. He telephoned airports in Switzerland, France, and Germany seeking a plane which would be able to transport the drug once it was obtained. He discovered that the last flight from Switzerland to Poland would leave in an hour, so he alerted the Swiss police to arrange rapid transportation to the plane. By 5:30 Dubret had been unable to locate the drug, so he called the newspaper "La Swisse" where reporter, Raoul Reisen, responded to the request for assistance in obtaining the drug. Riesen called several pharmacies, and finally he called the pharmacist of Geneva Hospital, Albert Rochat, at his home. Arrangements were made to supply the drug from the hospital, but first it was necessary to contact SP3AUZ once again to obtain additional information regarding the exact chemical composition of the medication in relation to the age of the child. Within fifteen minutes of finding the drug, contact was made with Nowa Sol. SP3AUZ, Julius Schmidt, telephoned the hospital at Zielna Gora, which was twenty kilometers from Nowa Sol. Twenty minutes later, under conditions which were very difficult: static, interference, changing propagation, the formula was on the desk of Dubret. Contact had finally been reestablished on a different frequency.

By 6:15 p.m. the medication was ready. Unfortunately, the last flight to Poland, which had been held until the last possible moment, had just taken off.

Dubret immediately instigated another search for a flight to Poland; again reporter Reisen assisted. This time the Public Relations Department of Air France responded. Two stewardesses from Geneva and two at Orly were requested to deliver the medication from Geneva to Paris, and to the crew of Flight 724: Paris, Varsovie, Moscow. By 9:00 p.m. the packet was enroute from Geneva to Paris, and by 9:00 a.m. Paris confirmed that the medication was on its way to Poland.

Because of the difficulty in delivering the drug across the iron curtain Dubret had called the Polish Delegation assigned to the United Nations in Geneva, requesting their support in the safe delivery of the drug. The Delegation sent telegrams to the ambassador from Poland in Paris, and to the ambassador in the USSR. Dubret was

Dr. Kuchincki who saved Marek by diagnosing the illness and ordering the drug.

Railway station at Zicklova Gora, where the drug was passed from the engineer to Marek's father.

Hostess Amik Renouf giving the medicine to a member of Swissair to be flown to Geneva.

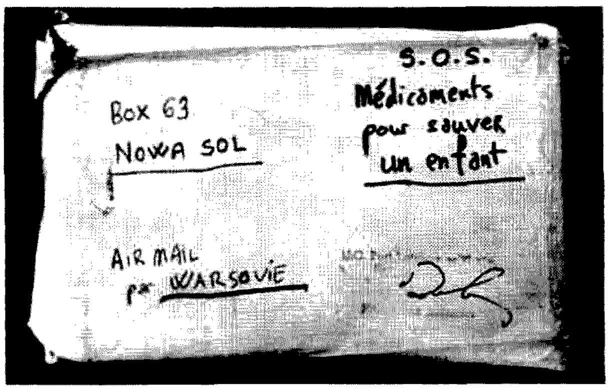
assured that the pilot of Flight 724, who would make only a short stop at Varsovie, would be authorized to leave the medication.

Between 10:00 and 11:00 a.m. Dubret broadcast to radio amateurs in Varsovie requesting that they go to the airport. (He also alerted amateurs in England and Sweden, for their propagation toward Poland was much more favorable.)

At the airport in Varsovie the response was amazing. There were numerous volunteers and well-wishers awaiting the arrival of the packet, eager to be of assistance. When the medication arrived, radio amateurs took charge, sending one part by police car, and another by train where it was entrusted to the engineer. Thus the medication was rushed from Varsovie to Nowa Sol.

By 2:00 p.m. Dubret had learned that the delivery had progressed as planned; and by 6:00 p.m. Polish amateurs informed him that the child, Marek Maziarz, had received his first injection within one hour of the appointed critical time. The medication was scheduled to be administered at regular intervals thereafter.

The next day while he was at work, Dubret received the news that the attending physician had stated that "without the Cosmegene, which arrived in time, I would have been able to do nothing; now the child will be saved." Following this the child's father thanked Dubret personally by radio and informed him that Maziarz, himself, had received one packet of medication from the engineer of the Varsovie - Nowa Sol express. Dubret received a report on the child's progress from the father. The child is now alive and healthy. ■



The original packet containing the drug. This package is now kept as a souvenir in the hospital where all say that Marek was saved thanks to radio amateur network.

The Polish group consisting of SP3CW, SP3AUZ, SP3BES, with Marek's father, Eugen Maziarz.

Marek after his discharge from the hospital fully recovered.

A Better Balanced Modulator

Balanced modulators have been a vital part of amateur transmitters ever since development of interest in single-sideband. Although improvements have been made from time to time, most circuits still require resistive and capacitive balancing by means of adjustable elements. Unfortunately, the long-term and temperature stability of this approach is dependent on the characteristics of the pots and trimmers used. Temperature effects can be minimized by use of compensating elements but the whole process now becomes very involved. Circuit unbalance means not only carrier leak but greater distortion for a given audio input. The purpose of this article is to provide an introduction to a circuit capable of providing the same order of carrier rejection as conventional modulators with much better temperature and time stability. It can do this with absolutely no initial or routine maintenance type adjustments.

I claim no originality for development of the basic circuit since it is widely used in industrial and military equipment. All measurements performed and the resultant data were done by myself in the process of implementing the circuit in a home project.

The circuit shown in **Fig. 1** can be recognized as a ring modulator whose operation is adequately described in the literature[1]. T1 and T2 are usually wound in trifilar form on toroidal ferrite cores since this provides close coupling and more uniformity than other types of construction. Randomly selected diodes will provide about 15 or 20 db of carrier suppression below the double-sideband output. This figure can be increased to about 30 db at *if* frequencies with careful matching of the diodes. It is soon evident to the experimenter that any further improvement can only be obtained by the addition of balancing adjustments. The reason for this threshold is a basic limitation of the trifilar winding coupled with the method used for driving the transformer. Due to the single-ended input, one side of the secondary has more capacity to ground than the other. This unbalanced capacity has increasing effects as the operating frequency is raised.

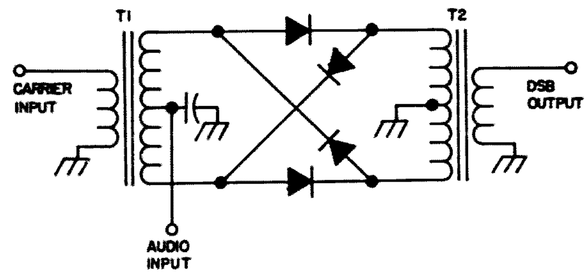

Fig. 1. Conventional ring modulator.

The easiest way to neutralize the effect of this unbalanced capacity is to isolate the return side of the primary from ground. This can be done by the arrangement shown in **Fig. 2.** T1 is a bifilar wound transformer with unity turns ratio which serves to isolate the primary return to T2. It may not be immediately obvious, but there is no loss of power in this transformation. The requirements that must be met are that the turns ratio be unity and the coefficient of coupling must approach unity. The mathematics used to prove this are not presented here since they are not common knowledge to most amateurs. The above requirements can be realized by the use of a bifilar winding on a toroid core.

The complete schematic of a practical modulator for use in the range of about 2 to 30 MHz is shown in **Fig. 3.** No tuning is used since T1 through T4 are broadband in nature with the impedance levels shown.

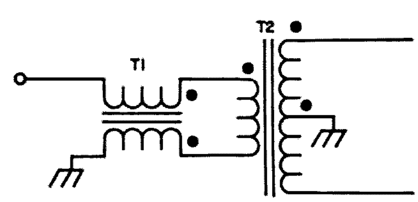

Fig. 2. Method of reducing effect of unbalanced capacity to ground in T2. Dot markings are explained in Fig. 4.

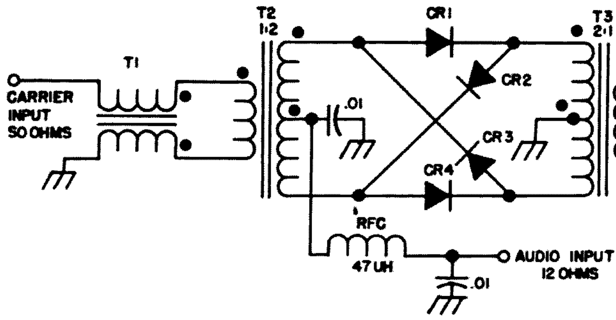

Fig. 3. Schematic of the wideband balanced modulator. The dots indicate winding polarities. Bifilar and trifilar winding is discussed in the text. Coil data: T1, T4-20 turns #32 enamel bifilar wound on 0.23 inch o.d. Ferrox cube toroid core (3D3 type ferrite). T2. T3- 30 turns #32 enamel trifilar wound on same core as T1 and T4. CR1, CR4- hot carrier or high speed silicon diodes.

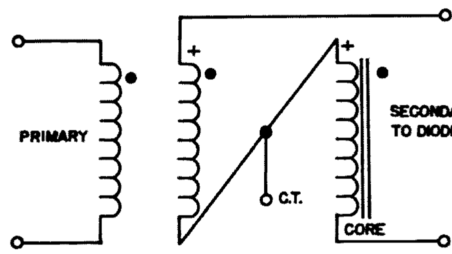

Fig. 4. Detailed illustration of the trifilar transformers, showing hookup of the three windings. The dots indicate that a current entering the primary in the direction shown will induce positive voltages at the ends of the secondary windings marked by the dots.

When terminated with a 50 ohm load at the output, the impedance looking into the carrier input is 50 ohms. With 1 volt rms of carrier injection, the impedance at the audio input is approximately 12 ohms. From the impedance levels it can be seen that this circuit is suited to transistorized circuitry but can be adapted for tubes.

Measurements were made at frequencies of 3 and 9 MHz, corresponding to the usual range of *if* frequencies used in amateur equipment. Equipment used consisted of an HP-606 *rf* generator, wto HP-200CD audio generators, an *rf* millivoltmeter, an *af* millivoltmeter, and a Singer spectrum analyzer. Optimum carrier injection at both frequencies is about 1 volt rms. Optimum audio level at this point is about 200 millivolts rms total (140 millivolts per tone for a two-tone signal). At 3 MHz, these operating conditions result in a double-sideband output of 137 millivolts rms with the carrier suppressed by 52 db below either tone. Intermodulation distortion is better than 50 db down. At 9 MHz, DSB output is 130 millivolts rms with a carrier suppression of 45 db and IM rejection of better than 50 db. At 30 MHz these figures will be degraded by a few db. High frequency performance can be improved by using fewer turns on the transformers. A higher carrier level will result in lower distortion but less carrier suppression. Less carrier injection will have the opposite effect. The figures given above seem to be a good compromise.

For those interested in using the circuit, a few construction hints are in order. It should be evident that the circuit can be stuffed into a very small space and hidden on a printed circuit board or in a corner of a chassis since no access to it is needed. An unclad epoxy board should be used to minimize unbalanced coupling to ground. The circuit layout should be symmetrical. Actually, the schematic gives a good physical layout and was used in the experimental unit. T1 and T2 should be placed at electrical right angles to eliminate mutual coupling. The same goes for T3 and T4. The close proximity of the cores makes this necessary as will become evident to anyone who experiments with the position of the cores while monitoring the carrier suppression.

The bifilar winding is formed by taking two pieces of wire, each of sufficient length to wind the required number of turns on the core, and twisting them together to form a twisted pair. This composite wire is then wound evenly around the core. The trifilar winding is exactly the same, except a third piece of wire is added to form a twisted triple. Referring to **Fig. 3**, 20 turns bifilar wound actually means 10 turns of a twisted pair. Similarly, 30 turns trifiler wound means 10 turns of a twisted triple.

The diodes should be matched by choosing

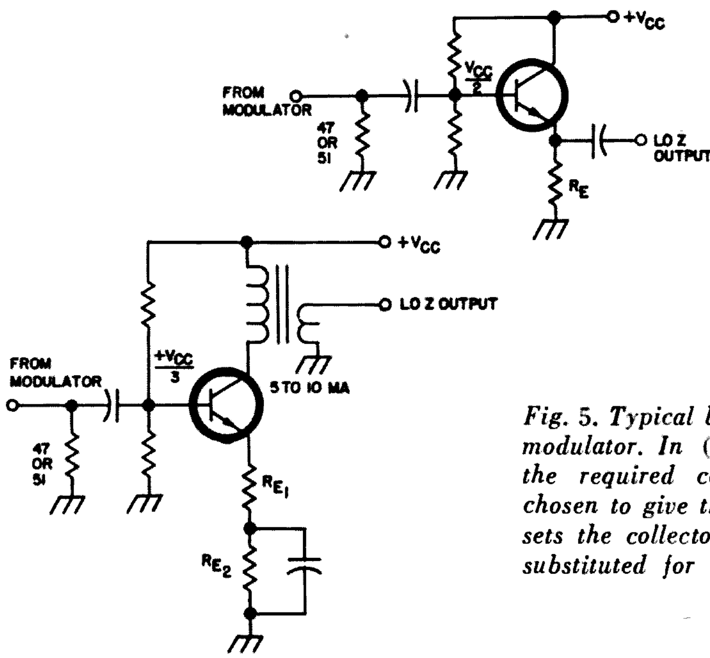

Fig. 5. Typical buffer amplifiers for terminating the modulator. In (A), Re should be chosen to give the required collector current. In (B) Re_1 is chosen to give the required voltage gain, while Re_2 sets the collector current. A tuned circuit may be substituted for the broad-band output tranformer.

those with the closest forward resistances on the XI ohms scale of a VTVM or TVM. Those with lower forward resistances are better from an efficiency standpoint. Most any silicon diode will have much higher back resistance than is necessary for proper operation. The zero-basis capacity is a more important consideration and should be no more than a few picofarads. The lower the better. Germanium diodes should not be used since their characteristics are not suitable for use in this circuit as regards efficiency and distortion. Hot carrier diodes have proven themselves more desirable at the higher frequencies. Another good choice for the diodes would be the RCA CA3019 which is an integrated circuit diode array. The advantage of using a unit like this is the excellent matching and temperature tracking of the diodes.

The modulator can be unbalanced by inserting a variable dc voltage of 0 to about ±1.5 volts at the audio input. This should be fed through a choke of 200 mH or more to avoid disturbing the audio frequencies. It is also worthwhile to mention that the load resistance at the output terminal should be kept in the vicinity of 50 to 100 ohms for proper operation with the circuit constants shown. Probably the most reliable way of obtaining a constant 50 ohms is by shunting the output with a 50 ohm resistor and using a buffer amplifier. **Figs. 5a** and **5b** will illustrate.

This circuit is not limited to use as a balanced modulator. It functions very well as a low distortion product detector by adding a step-up transformer at the audio terminal to bring the impedance level up to 10 or 20K ohms. With an *if* input of about 100 millivolts rms, a few volts of audio will be pro-

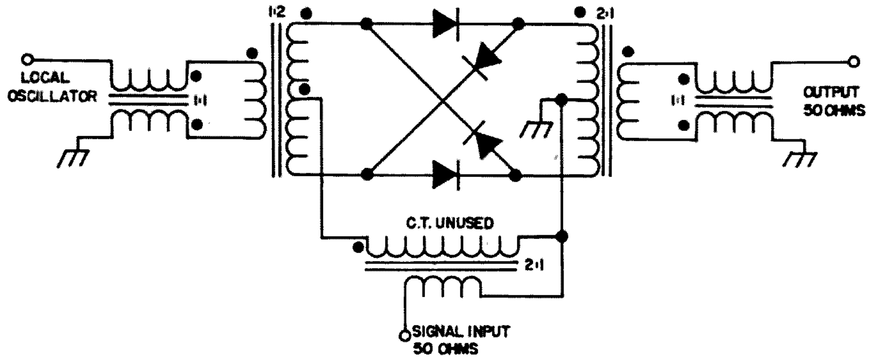

Fig. 6. Wideband balanced mixer. Transformers and diodes are the same as in Fig. 3. Signal levels should be the same as for balanced modulator service.

duced at the secondary of the matching transformer. This can be fed directly into a power output stage using a pentode. A lower step-up from the detector should be used for a transistor output stage. The dynamic range of this detector is on the order of 130 db. The addition of a third trifilar transformer makes the circuit useful as a well-balanced mixer over the range of 2 to 30 MHz as shown in **Fig. 6.** Dynamic range is about 130 db with suitable diodes (hot carrier or very high speed switching types). Of course, a filter is needed after the mixer to remove the unwanted sideband. A voltage-controlled attenuator can be realized through the use of a variable dc voltage applied to the audio terminal. The *rf* signal to be controlled is fed into either of the other ports and is taken out from the port which is left. Signal input at the *rf* ports should not exceed a few hundred millivolts to avoid distortion. A little thought will reveal many other applications of this circuit.

I hope the information presented above will enable the homebrew artist to make his gear a little more up to date and at the same time get rid of that unpredictable carrier balance control.

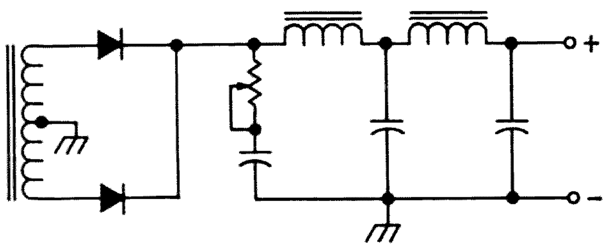
An Adjustable High Voltage Supply

William P. Turner WAØABI
5 Chestnut Court
Saint Peters, Missouri 63376



I am sure that every ham who ever built a power supply has had the sad experience of coming out with a voltage which was too high or too low for the project at hand. The usual practice is to try changing from a capacitor input filter to a choke input, or the reverse, in order to raise or lower the available voltage. Sometimes this works, that is if the voltage requirement is not too critical. Other times it doesn't, and we resort to expensive, power consuming, and poorly regulated voltage dividers.

As an example of a much more satisfactory method, let me relate my recent experience with a transceiver power supply. I had bridge rectified a TV transformer for high voltage and intended to take the low voltage off the center tap of the same transformer. The high voltage came out exactly right, the low voltage, which was to have been 250 volts under a 100 ma. load, came out at 230 volts with a choke input filter. An attempt at changing to a capacitor input failed miserably. 350 volts was much more than the rig could endure. It looked like time for the 20 watt resistors and all of that nonsense.

It would seem from the above that what was required was a filter which would operate somewhere between the choke and the capacitor input conditions, and this what I ended up with. In the diagram you will note a resistor in series with the positive lead of the input filter section. This resistance, when fully in the circuit, seriously limits the ability of the capacitor to charge and as a result the output voltage is reduced almost to the value of a choke input. On the other hand, when the resistor is reduced in value, the input filter charges to a more normal voltage and the output reflects this change. As may be seen from these two examples, it is possible to adjust the output voltage by merely adjusting the series resistor for the desired voltage at the required load.

It would be desirable to substitute a rheostat or adjustable resistor for setup purposes and replace it with a fixed resistor when the exact value is known.

I would suggest that values below 1000 Ohms would be most useful. In the example cited above a 500 Ohm, 10 watt resistor was used. Try it, it works like a charm.

"Henry is Spending the day in bed with a code."

Save Your Money!

Long Beach, Calif. 90803

Don't throw away those audio and power transformers when they develop a defect. You might be able to repair them without much difficulty, or salvage them for other uses.

Most transformer troubles are shorted, or open, windings, shorts between separate windings, or shorts to the core. In a number of cases you will find some of these defects at the terminal points of the primary or secondary windings. It is best to remove the outer metal shell of the transformer and inspect the terminals for a broken wire or loose solder job. Should the terminal leads of the windings be of covered wire, it is best to check them as the heat from the equipment sometimes causes these leads to get brittle and break.

With center-tapped windings, an open will occur if the common connection is broken. Filament and high voltage windings are frequently center-tapped by bringing the two leads from the windings through a piece of spaghetti tubing and soldering the two leads together at the end. Sometimes this center-tapped lead may be cut too short when being assembled at the factory and may break the common lead and create an open. A repair can be made by stripping the insulation on the center tap lead and resoldering the two wires. This same proceedure should be used with tapped modulation or audio transformers.

A short to the core can usually be repaired without too much work. In numerous cases it is common practice to ground one side of the transformer as, for example, the filament plus winding. If a short should occur, all that is necessary is to reverse the leads of the filament windings. Should a short be found at some other point on the windings of the transformer, check it over visually, as the insulation may have worn off the wire and is grounding against something on the transformer. When the short is located, repairs can be made by using varnish or electrical tape. With internal shorts in the windings, it is best not to try to make repairs unless you are an experienced hand on re-winding jobs.

Now for some ideas to salvage those transformers in your junk box. A power transformer with an open high voltage secondary can be used as a filament transformer or a filter choke. When used for a filter choke, use only the primary leads and tape the secondary leads for safety. If the filament windings of the secondary are open, you can still use the transformer for the high voltage. With the primary winding open you can get surprising results by using the transformer for audio output. Connect the high-voltage secondary as the primary and the five or six volt filament winding as the secondary. Experiment with both sets of leads for best results.

Suppose you have a low power rig and need a cheap and easy way to modulate it. Dig that audio frequency output transformer with the open secondary winding out of your junk box and use it. Why not try Heising screen modulation? It may not be the best modulation but it will work well in any emergency. All you need is the primary of the transformer and a few inexpensive components and you are in business. Any ARRL Handbook will give you the circuits; transformer-coupled or clamp tube arrangements.

You can always use those small audio output transformers for small power supply chokes. All you do is cut off the secondary leads and use the primary. You will be surprised how many other applications these small transformers have if you try them in some of your pet projects.

Where transformers are beyond repair and can not be used for any of the ideas suggested in this article, salvage the wire from the coils. This will give you a good stock of wire to use for inductance coils. You can sell the iron core to the junk man.

Although this article refers to power and audio transformers, the same ideas can be used for salvaging interstage or modulation transformers. A word to the wise is sufficient; SAVE MONEY. . . . K6GKX

Transistor Oscillators

Calvin Sondgeroth W9ZTK
715 N. Elm Street
Sandwich, Illinois 60548

Many pieces of amateur radio equipment —transmitters, receivers, test equipment and the like use oscillators in one form or another. These circuits generate ac voltages at fixed points across the entire communications spectrum. The signals generated by these devices are the heart of all communications systems.

In the beginning, amateurs used the spark gap as a rather crude method of generating *rf* energy. Frequencies were unimportant then and methods of detecting the energy sent by a transmitting station were also rather crude. The development of the vacuum tube made possible the generation and detection of signals with much improved quality and more precise control of frequequency. Through the years many tube oscillator circuits were developed with each having its own advantages with regard to stability and the frequency range to be covered. Indeed, even today a large percent age of amateur equipment in use still uses vacuum tubes.

During the last five or ten years, the transistor has begun to creep into amateur designs and a few commercial pieces of ham gear have become entirely solid state, except maybe for the last power producing stages of amplification. The semiconductor approach to communications equipment design offers a number of advantages over vacuum tubes in terms of power requirements and thermal considerations. This article describes and diagrams a number of solid state oscillator circuits which can be used to generate energy over a very wide frequency range. Each circuit, of course, has particular merits over a given band of frequencies.

Resonators

The dictionary defines the verb oscillate as "to swing to and fro like a pendulum." This definition is obviously directed at mechanical devices and might not seem to apply to electrical circuits. Not so. An electronic oscillator produces a signal which behaves in just such a way. The energy generated is in the form of an ac voltage which changes alternately between positive and negative potentials with respect to a zero reference level at a constant rate per unit time. This is the same as the motion of a clock pendulum swinging back and forth across a vertical line. The electrical analogy of this sort of mechanical system, of course, is the resonant or tuned circuit. It has a natural period of vibration so to speak in terms of the voltages and currents in its elements at a given time. A tuned circuit can be used in an oscillator to generate alternating current energy at its resonant frequency.

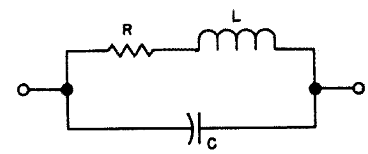

Fig. 1. *A parallel tuned circuit.*

To go back to the pendulum of a clock, it can be noted that the clock must be rewound periodically in order to keep it going. Because of the frictional losses in the various parts, the pendulum will not continue to swing forever once it is started. To keep the pendulum going over a long period of time it is necessary to give it a little kick with the spring mechanism in the clock each time it completes a swing. Electrical resonant circuits are exactly the same. A parallel resonant circuit is shown in **Fig. 1.** The inductance and capacity in the circuit produce the effect of making the circuit sensitive to oscillatory electrical vibrations at a particular frequency, and the resistance R is analogous to the frictional losses in the clock mechanism. Indeed if the resistance were zero (this is physically impossible) the circuit would oscillate and generate ac energy forever once it was pulsed with a signal at its natural resonant frequency. Maybe this is fortunate since if the resistance were not present, the tuned circuits that we devise would produce incessant oscillations excited by signals from broadcast stations, etc.

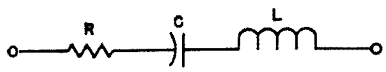

Fig. 2. A series resonant circuit.

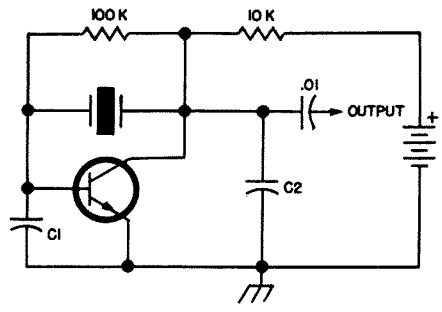
Oscillators in general

An oscillator circuit adds the "kick to the pendulum". The active and passive elements of the circuit combine with the resonant circuit to keep it oscillating as long as power is supplied. Turning on the power produces enough noise (kick) to start the circuit oscillating. This brings up the matter of "Q" or quality factor of the tuned circuit. Q is defined as the ratio of the stored energy in an oscillating system to the energy lost per cycle of oscillation. In electrical circuits it can be thought of conveniently as the ratio of the ac reactance to the dc resistance in the circuit. Circuit losses make up part of this resistance and must also be taken into accounty. For example, placing a coil close to a ground shield may increase the coil loss, and thus the effective resistance, lowering the coil Q. The subject of Q is really quite involved, but it is only important to realize that it is necessary to furnish a little energy to a tuned circuit or oscillating system after each oscillation in order to compensate for the system losses to keep it in oscillation.

Almost any circuit with a resonant network will oscillate as many of us have discovered when trying to build devices which are intended for uses other than producing *rf* energy. This comes about because an oscillator is just an amplifier with the appropriate elements to produce oscillation. To provide the "kick" to the resonant circuit, it is only necessary to return a little bit of the energy from the output of the amplifier to the input in the proper phase relationship. Under this condition the amplifier will generate a signal at the natural resonant frequency of the network. In order to do this, of course, the gain of the amplifier must be greater than unity so that some power is left over to return to the input to keep the system going. The amount of power required to keep the oscillator excited depends upon the Q of the frequency determining circuit. The lower the Q, the more returning or feedback power required.



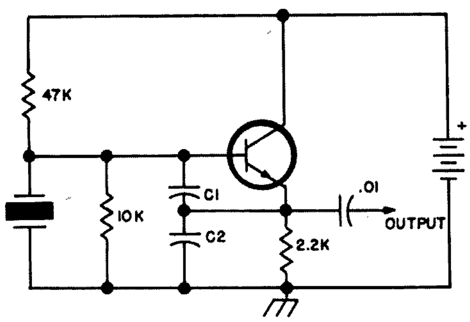
FREQUENCY RANGE	C1	C2
200 KHZ - 1 MHZ	1000 PF	470 PF
1 MHZ-5 MHZ	680 PF	390 PF
5 MHZ-30 MHZ	220 PF	180 PF

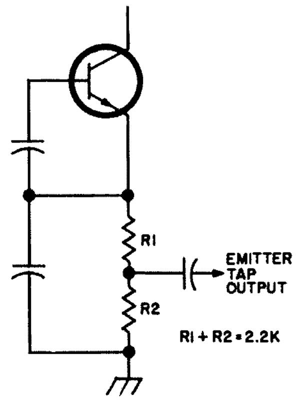
Fig. 3. Pierce oscillator circuit.

Crystal oscillator circuits

The resonant circuits for oscillators are usually made up of coils and capacitors. However, the piezoelectric quartz crystal is commonly used in amateur equipment, and this type resonator will be discussed first. A crystal is really the same as an LC network and such networks can replace it in almost all frequency determining circuits. The crystal has the very distinct advantage of having a very high Q and can be used to generate signals of much better stability than a coil-capacitor combination. Here it might be well to mention that most crystal oscillators use parallel resonant tuned circuit operation. This is the connection shown in **Fig. 1.** Some circuits make use of the series resonant condition shown in **Fig. 2.** Here the network presents only the circuit resistance at the resonant frequency while the parallel circuit of **Fig. 1** presents an extremely high resistance at resonance. A crystal not only acts like a tuned circuit; it can look like a parallel resonant circuit (**Fig. 1**) or a series resonant circuit (**Fig. 2**) depending upon how it is connected in the oscillator circuit. A complete discussion of why this is so is beyond the scope of this article, but information on crystals may be found in the literature. In the circuits to be described, the crystals are operating in a parallel or anti-resonant mode unless series operation is especially noted.

All of the circuits and values are designed around a good quality silicon npn transistor such as the 2N706. This device will work well in oscillators up into the vhf range. Other types are useable and type number is not too important as long as the





FREQUENCY RANGE	C1	C2
1-4 MHZ	820 PF	390 PF
4-10 MHZ	470 PF	220 PF
5-30 MHZ	220 PF	100 PF

Fig. 4. *Alternate* 1-30 *MHz oscillator.*

transistor is rated for the frequency to be generated. Supply voltage polarity is for the npn configuration and can be between 6 and 15 volts. Nine and 12 volts are good nominal battery values. For the circuits that require capacitor value changes with frequency, nominal values of capacitance are tabulated. Bias resistor values are nominal and some experimentation with R and C values may be needed for optimum results depending upon frequency and the circuit involved. In general the values indicated will produce good results.

Crystal oscillators for 200 kHz - 30 MHz

An old standby vacuum tube oscillator is the Pierce circuit with the crystal connected between plate and grid. A transistor version of this circuit is shown in **Fig. 3.** Here, as in the vacuum tube version, the crystal is connected in the same relative position, i.e. between collector and base on the transistor. It will be noted, however, that the semiconductor version of this circuit has some capacity added between the "hot" elements and ground. Transistors just don't have the intereleetrode capacitances that vacuum tubes do and their low impedance nature makes these capacitors necessary. They provide the feedback to make the transistor oscillate. Suffice it to say that this circuit will work from 200 kHz to 30 MHz.

Another circuit for about the same frequency range is diagrammed in **Fig. 4.** It will not work down as low as the Pierce, but will produce good results in the range from 1 to 30 MHz. This circuit is similar to the Clapp vfo circuit described later. The feedback capacitors in series from base to ground should be as shown to achieve a proper feedback ratio for the design frequency. This circuit is about the same as **Fig. 3** except that the transistor is operated in a grounded collector connection. Output can be taken from the emitter directly, or some isolation can be realized by splitting the emitter load into two resistors and taking the output from their common connection.

Crystal oscillators for frequencies above 30 MHz

At higher frequencies, crystal design dimensions become such that it is necessary to use quartz resonators in an overtone mode. Indeed crystals with fundamental frequencies up to 30 MHz or so are built, but their thickness dimensions reduces to only a few mils. Above 30 MHz it is easier to use a piece of quartz of more convenient dimensions and excite it on its 3rd, 5th, or 7th overtone (harmonic) in the oscillator in which it is used. The overtone frequency is not an exact multiple of the fundamental frequency of the crystal, but that is not important here. **Fig. 5** shows a circuit for use with overtone type crystals. It is a Hartley oscillator and the transistor is used in the grounded base configuration. The tank circuit in the collector should resonate at the overtone frequency of the crystal. The ratio of the capacitors across the tank coil determines the amount of feedback, and making the capacitor at the bottom end of the coil smaller will increase it. Here the output can be taken from either the collector or emitter of the transistor. This circuit makes use of the series resonant (short circuit) properties of the crystal to excite the amplifier. Here there is no phase reversal between emitter and collector and the crystal feeds back energy to the emitter in phase by virtue of its low impedance at the series resonant frequency.

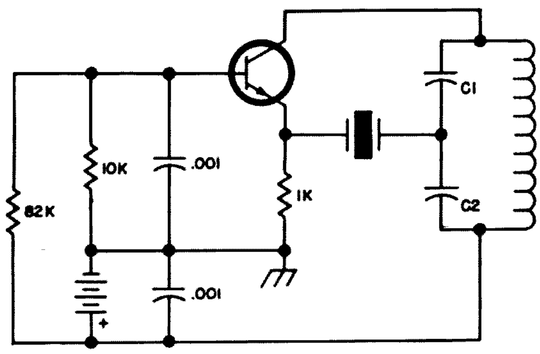


Fig. 5. *An overtone crystal oscillator.*

Low frequency crystal oscillators

Crystal controlled oscillators at 100 kHz are very useful for spot frequency checks in amateur receiving equipment. Transistors can be used at this frequency quite easily with the proper circuitry. The range from 20 to 200 kHz can be generated using the circuit of **Fig. 6.** A close look will show that this is the same circuit as **Fig. 2** except that an LC tank has been added to increase feedback to overcome the higher resistance of the lower frequency crystal. The tank circuit values can be computed from the formulas for the crystal frequency to be used. The coil can be an *rf* choke of about the right value and the tuning adjusted by CI.

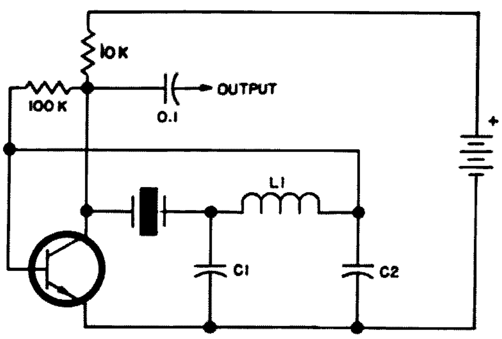

Fig. 6. *A low frequency crystal oscillator.*

An alternate circuit for low frequency use is shown in **Fig. 7.** It has the advantage of not using a coil and good results can be obtained with the values on the diagram from 20 to 200 kHz.

These crystal oscillators will give coverage from 20 kHz to 150 kHz with the proper crystal, adjustment and tuning. Before passing on to self controlled oscillators which can be moved about in frequency, it might be well to comment on the frequency accuracy of crystal oscillators. As has often been mentioned in the past, the marking on a crystal does not mean that its frequency is that plus or minus zero. Its oscillating frequency is determined primarily by its physical dimensions and finishing, but it is also affected by the oscillator circuit it is used in. All crystals are designed to work into a specific load capacitance (usually around 32 pF) for parallel or anti-resonant operation. To provide this load capacity it is important to put a small trimmer capacitor in series with the crystal in each of the anti-resonant circuits above if exact frequency

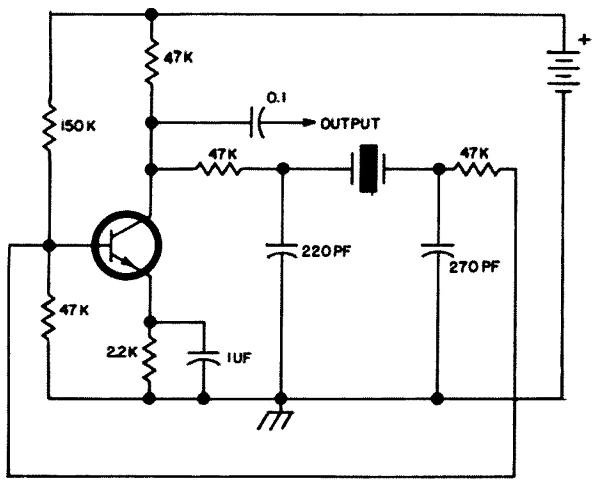

Fig. 7. *Alternate low frequency crystal oscillator.*

adjustment is necessary. In cases where a frequency error of a few kHz is not important, the trimmer can be omitted. For 100 kHz standards etc., it is a must.

Variable frequency oscillators

Crystal oscillators are extremely useful for generating precise spot frequencies, but the high Q of the crystal makes the adjustment range quite narrow. Where a wide band of frequencies is to be covered by a single oscillator a tuneable device is necessary. In the circuits just described, the crystal can be replaced with an LC resonant circuit which can be adjusted to the frequency desired. The stability of such an oscillator is not as good, but the ability to adjust the frequency over a wider range is quite useful. The variable circuits below are a bit different in schematic form, but their operation is identical to the crystal oscillators.

A circuit that is often used in amateur transmitters is the Clapp vfo. Its semiconductor version is shown in **Fig. 8** and, as noted, is similar to the crystal controlled

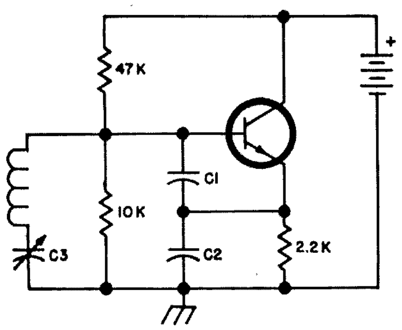

Fig. 8. *Clapp VFO oscillator.*

circuit of **Fig. 4.** The coil, and the series combination of capacitors across it, resonate at the operating frequency, and the large values at C1 and C2 provide for loose coupling to the tuned circuit producing good frequency stability for use in a vfo.

In the tuneable circuit, it is important to make C1 and C2 as large as possible while maintaining reliable oscillation to keep the coupling to the active circuit as small as possible. Typical values at 3.5 MHz might be 2000 pF at C1 and 820 pF at C2. For vfo use, experimentation here is in order. The tuning capacitor C3 is a normal type for vfo's and toroidal coils lend well to transistor construction projects. Output can be obtained as in **Fig. 4.**

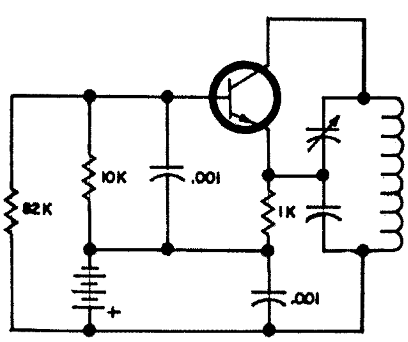

Fig. 9. *A general purpose oscillator for use up to VHF.*

The circuit just described will provide most of the rf frequencies for ham vfo use, but the circuit of **Fig. 9** can be used up to 200 MHz in test equipment, etc. It is of the same configuration as the crystal oscillator in **Fig. 5.** In the tuneable version of this circuit, the crystal is simply replaced by a short circuit and the tank circuit values in the collector control the frequency of oscillation. Without the crystal in the circuit the frequency stability is degraded, but this oscillator can be used up to vhf in a grid dip oscillator.

The circuit in Fig. 10 is shown as a matter of interest. It has no exact counterpart in the crystal oscillators described, but it will work well from 3.5 MHz on up into the vhf range. The transistor is connected grounded base and feedback is provided by the capacitor C1 from collector to emitter. C1 can be a small trimmer capacitor of about 30 pF maximum and used to adjust the feedback at the frequency range desired. L1 and C2 determine the frequency of oscillation.

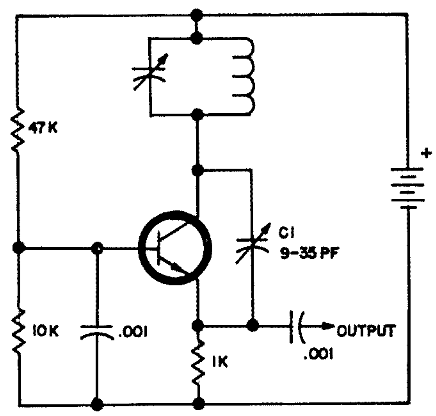

Fig. 10. *Another general purpose oscillator.*

Self controlled oscillators at the low and audio frequencies can be devised using tuned circuits, but their circuits are so many and varied that they are omitted here. At these frequencies oscillators commonly use RC time constant properties to produce the required signal; e.g. multivibrators, unijunction transistor oscillators, etc. The waveforms produced by these oscillators are more or less rectangular and they are intended for keyers and other timing circuits. The sinusoidal oscillators outlined in this article will give frequency coverage over the entire spectrum for amateur use and should be adequate for most purposes.

In closing it might be well to note again that the circuits and values shown are general. The usual ham method of "cut and try" may have to be used if the circuit doesn't oscillate at the first connection of power. Variations in crystals, tuned circuits and transistors are inevitable. The circuits and values shown provide a good starting point, and in most cases little adjustment will be necessary. . . . W9ZTK

Closed-circuit TV Camera

ATV RESEARCH announces the availability of its new line of SOLID-STATE MODULES for building your own TV camera (vidicon type) or for updating existing cameras. Through the use of these wired, pre-tested, encapsulated modules building a complete camera can be accomplished in a single evening. No previous TV knowledge or special test equipment is required.

Modules include: (1) Video module, (2) Vertical sweep module, (3) Horizontal sweep module, (4) RF modulated oscillator module and (5) DC-DC HV module.

Using the first four modules, experimenters and constructors can build a complete TV camera (less power supply). Power requirements include 12V for modules and focus coil, 6V for vidicon filament and 200 volts for the vidicon control circuitry through the use of the (5) module which amplifies and rectifies the horizontal sweep pulses.

These modules are compact, light weight and economically priced from $10 to $20 per module. Each module comes complete with hook up instructions.

Write ATV Research, Dakota City, NB, 68731.

Dear Kayla,

As an RTTY enthusiast, I was pleased to see several articles on the subject in the January issue. I feel I must comment on the WA8DCE article on page 42, however, as several statements are not only misleading, they are erroneous.

First ham radio pioneers did NOT develop "Frequency Shift Keying." We didn't even get on ham RTTY until after WW II, and "f.s.k." was in use soon after WW I by commercials.

The author mentions that 2975 is the "Mark" frequency, and that 2125 is the "Space" frequency. Not true, this is backwards, with mark always being the lower of the two, viz. 2125. The part that confuses most newcomers revolves around the use of lower sideband for receiving. The transmitted "r.f." is actually lowered for space, which then changes the tone in the speaker higher for audio. This is confusing, and most unfortunate, but that's the way it got started and remains to this day. You can listen on upper sideband, of course, but then the tones come out backwards in the speaker from normal. "H.F." and "V.H.F." techniques are identical, and the use of lower sideband for receiving on h.f. then gives the proper relationship of mark and space tones in the speaker (and also the RTTY demodulator).

When he spoke of the tones generated by the "a.f.s.k." unit into the mike input, he was correct–again, "lower sideband" position on the transmitter is used if it is a "s.s.b." type with suppressed carrier.

I hope this clarifies the situation, which is confusing enough even when understood perfectly.

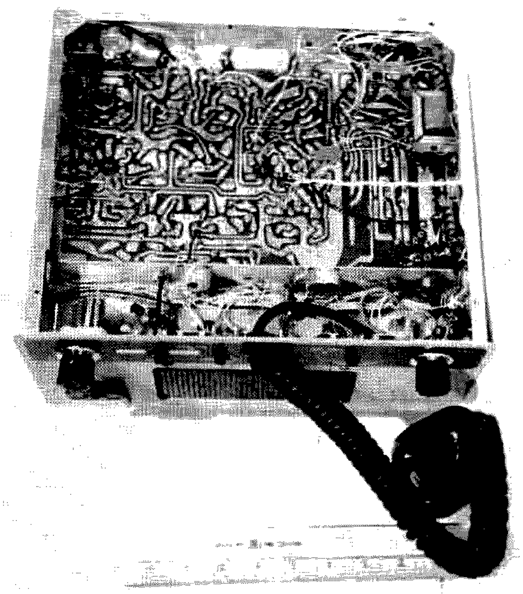
Heathkit HW18-3 160 Meter SSB Transceiver



Toledo has always been a town that was active on 160 meters. This goes back to the very early days when mobile operation was not permitted except on 5 meters. W8HSW and several others got together during this time and put a 160 meter rig in an automobile. The whole amateur fraternity of Toledo was really shook when they proceeded to come on the air one Saturday morning and moved all over town operating as a portable. Someone got so upset they called the FCC in Detroit to complain only to find out that W8HSW had written the FCC as required and advised that they would be operating portable from about 20 different street intersections.

As soon as the 160 meter band was opened for mobile operation, Toledo was quick to do something about it. It was easy to get the car BC receiver to tune to 1800 and not lose too much of the broadcast band. A simple two or three tube transmitter crystal controlled was easy to build. The end result was that Toledo had an awful lot of mobiles on 1812 kHz plus at least 5 boat mobile to say nothing of the home rigs that could operate on 160.

With this interest on 160 it was only natural that I should be interested when Heath Company announced they were going to put out a 160 meter Single Side Band transceiver. Very few of the SSB exciters covered 160. Down converters to go from 40 meters to 160 seemed such a waste of power.

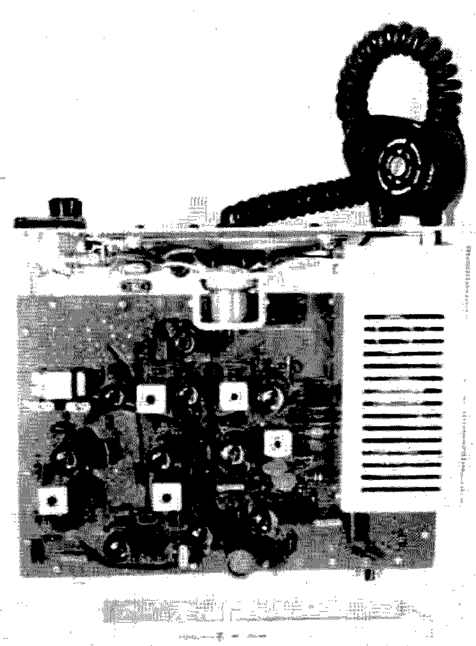
The kit was a little longer coming than I had planned and arrived a couple of days before we were to leave on four weeks vacation on our boat. I took the kit along so I could work on it on a rainy day and in the evening when all was quiet. I can now have great sympathy for those fellows who put a kit together in an apartment. I am used to a large work bench in the basement so this was a new experience for me. Pick up all the parts and put them away when Virginia had lunch ready, put them all away when we got ready for bed and be sure to store them real good so they would not upset in rough seas on the next day's run. Anyhow it went together in the usual fun way that all Heathkits have a habit of doing.

Sometime along the way the FCC changed the portions of the band that could be used

in various areas and also changed the input power limits in many cases by a considerable amount. As a result of this, interest in 160 has increased. I'll bet there are people on 160 that haven't been on since before World War II.

I was glad that I had the HW18-3 because I was in there with the rest of them with no trouble at all. The SSB or AM feature was sure good too. The two crystal control frequencies were OK but too often the other station would not be transmitting on same frequency as he was receiving. When it was explained that you were crystal controlled, it was no problem to get him to zero beat your frequency. The clarifier could then take care of any slight drift. It was surprising though how many of the fellows were crystal control, especially the mobiles.

It didn't take me long to find out that a VFO would make operation real fun. It also took even less time to find out the LMO in the SB100 tuned the exact range of frequencies needed for the VFO in the HW18-3. A simple coax cable with a crystal socket on one end and an RCA plug on the other and I was in business with a real fine VFO. The only drawback here was that the dial runs backward but you can easily get used to this. Any VFO that tunes 5.2 MHz to 5.4 MHz will work very nice. The instruction book tells all that is required for a VFO and anyone who wants to go this route should have no trouble.



Operating was real fun and contacts were made like back when I first got my ticket many years ago. Actually with sideband it didn't seem so crowded. Maybe this was due to the sharp crystal filter in the HW18-3. Enough of the operation of the rig, so now on to the technical.

Enough has been said in the past on the ease of construction of a Heathkit that I won't to into it here. No trouble was encountered in tuning and adjusting. The only trouble was that the HW18-3 takes 250 volts on the low side and both my power supplies were wired for the 300 volts. Since I wanted to use the same supplies for both rigs a switch was installed in both the ac and the dc supplies. By the way, a newer HP23A supply has the switch already installed.

One point that sticks out is that there is no relay used to go from receive to transmit. It's like magic, no relay clatter, the receiver goes dead and as soon as you talk into the microphone the meter swings. This is accomplished with several diodes. The first of which is a clever T-R switch in the antenna circuit where the diode is back biased to cut off so no rf can get to the receiver in the transmit position, but in receive the diode is like a short circuit. I checked with a calibrated signal and found no difference with the diode shorted out or with it in the circuit. While transmitting, the unused portion of the receiver is also biased quite high so that it is completely cut off. A T-R amplifier tube is controlled by the PTT switch on the microphone and this places the high positive bias on the T-R diode. This same portion of the PTT switch also control the negative bias on the receiver tubes, which are cut off when transmitting.

Except for the control system mentioned above, the circuitry is pretty much a standard dual conversion filter type transceiver. The *if* is the usual Heath 3395 kHz. A four crystal lattice filter gives good selectivity of about 2.1 kHz.

The transmitter ends up in a pair of 6GE5 beam power tubes. "Sylvania News" tell us that these tubes can be run in SSB service 1.25 times their regular rating which would be about 175 watts for one of them. Since Heath only runs them at 100 watts (200 PEP) they are not working too hard.

Provision is made to run in the AM mode by a front panel switch. In the AM position a minimum of 40 watts is run in the final and this is single sideband with carrier so that it appears much stronger than 40 watts of straight AM. The ALC action is a bit stronger here than on SSB.

As mentioned above, ALC is incorporated. This is accomplished by picking off any positive audio swing of the grids of the final caused by too much grid drive. The audio is rectified and filtered and used to control the transmitter *if*, mixer and driver tubes. The same circuit was high negative bias applied in the receive position which effectively cuts off the transmitter.

The tune up and alignment was so simple you wouldn't believe it. Adjust the slugs in the *if* coils for highest S meter reading and that is it for the receiver. The transmitter was just as easy. Set the bias, adjust a couple of slugs, then adjust the carrier null.

There is no final adjustment for the transmitter as this is all pretuned to match a 50 ohm antenna.

Checking the output on SSB showed that with a single tone signal, the unwanted sideband was down 47 db and the carrier was 46 db down after the balanced modulator was touched up just a bit. The output was just a bit over 105 watts PEP. On AM with no modulation the output was 20 watts and the modulation increased it. Good on the air reports were received from everyone when using either mode and, of course, the SSB signal was much more potent.

The receiver performance is really something, I thought that the all band receiver I have been using was good but this one is better. You would be surprised at how much the noise is reduced with the sharp 2.1 kHz filter. I didn't think it possible that the 4 crystal filter would be this sharp but I couldn't prove any different. The sensitivity was better than the 0.5 microvolts that Heath claimed by about .01 microvolts.

With the new FCC changes for 160 meters there should be a lot of activity this year. Here is quick easy way to get there and much better than a transverter. My antenna leaves a lot to be desired so I'm going to have to do something about that, maybe a vertical on top of the tower.

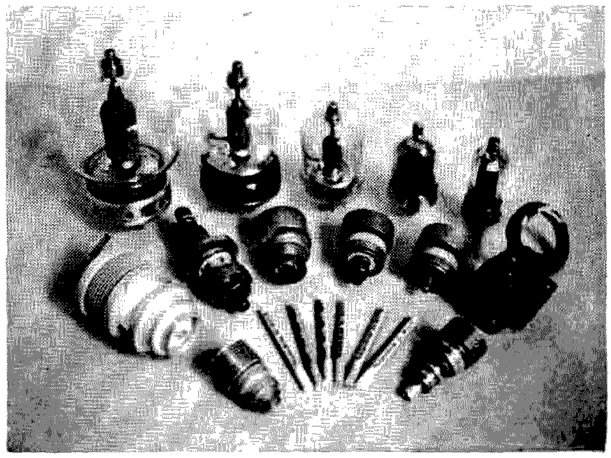
. . . W8QUR

COOL IT!

David Oliva—K9CNN
818 *Valley View Dr.*
Glen Ellyn, Ill. 60137

When constructing any piece of electronic gear that requires cooling, the average ham often does not have available to him the equipment or information to do a first class job. Even with the proper blowers available, if improper techniques are used, inadequate cooling may result in tube and circuit damage. Math as applied to air flow is fine but unfortuantely few hams have the patience or associated equipment to use it. The following article was written with the hope that it will put and keep more hams on the air with their favorite VHF rigs.

At hamfests, auctions and surplus stores be on the lookout for blowers of various types. Do not be afraid to use large size blowers if mounting is practical. Squirrel cage blowers are to be preferred over dc high rpm surplus types. The high rpm blowers do not last very long in continuous service and also produce a terrific racket. This is the price paid for small size. Higher RPM cage types are to be preferred over lower rpm blowers for cooling VHF tubes with special air system sockets such as the 4X250 series.



Some VHF tubes requiring forced air cooling. Top left to right; 5D22-4-250, 4-125, 4-65, 6146, 2E26, *can be cooled by low velocity type blowers.*

Middle row; 6283, 6383 *(water cooled)*, 8119, 4CX250K, 4CX250, BL800 *klystron (may be conduction cooled also).*

Bottom row; 6884, *Thermochrom temperature indicator crayons*, and* 2C39. *These tubes are best cooled by medium to heavy duty high speed blowers of the squirrel cage type and may take up to* 1/6 *HP motors with speeds from* 1800 *to* 3600 *RPM.*

A 1296 *MC tripler using a favorite cooling method here. No back pressure is produced by blowing the air across the cooling fins of the* 2C39. *Running in tripler service with* 800 *volts on the plate and in excess of* 10 *watts RF out, the tube and blower are both cool! This would not be possible with this small blower in an enclosed cavity construction. The blower is mounted on rubber grommets to avoid "blower modulation" of the tube. This may happen with high frequency tubes because of the close element spacing required.*

Flexible tubing and clamps of all types can be useful in making connections from the blower to the area to be cooled. A central air box with several outlets of smaller tubing can be used to cool several small tubes. This eliminates the necessity of making a pressurized chassis which is sometimes inconvenient.

Small holes in sheet metal boxes can be very conveniently plugged with epoxy cement which will stick to almost anything. Be careful not to put epoxy on any screws you might later want to remove as this could prove a calamity!

A good "poor man's" blower can be made from a phonograph motor, using a small fan blade mounted in a tin can with the ends removed. Brackets can be used to mount the can near the tube to be cooled. Rubber grommets should be used to mount the motor to minimize the vibration. This arrangement makes a neat little wind tunnel that is easy to handle for small cooling jobs.

Screening over open areas for rf tight enclosures must be chosen with care. Small mesh screening is to be avoided as it will slow the air flow. Pre-punched aluminum screen is to be preferred, or even make your own covers with 3/16 to 1/4 inch holes for the air to escape. Remember that the larger the area to be cooled the more air flow you need. The more obstructions to the flow such as sockets, chimneys and tubes, the more high speed air you will need to do the job.

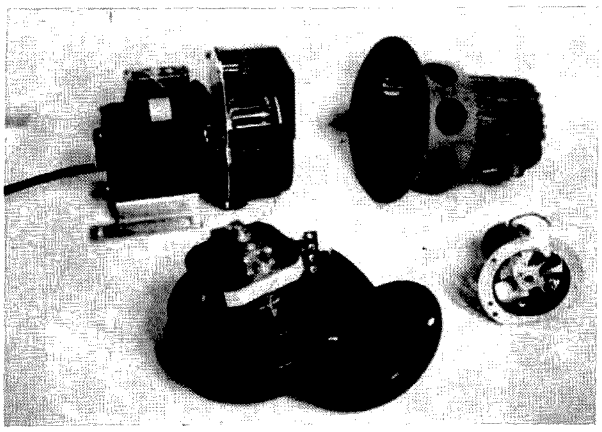
Your blower may speed up after installation is complete and all plates are in place for an air tight compartment. This is an indication of too much back pressure and will cause blower overheating. A larger blower is in order or this condition may be relieved by partially blocking the air *intake.* This will slow down the blower to its normal speed but will decrease the cooling efficiency of the system. The best solution for a situation like this is a blower that will handle higher back pressures, and this is not necessarily cured by the size of the blower.

Rules for cooling—

1. Don't add on the blower as an afterthought. This will complicate construction of a rig enormously and the blower selected sometimes will not fit at all!
2. Get the blower as close to the tube as possible for best cooling.
3. Use a small enclosure in preference to a big one; make an enclosed box for the tube to be cooled with input ***and output*** holes.
4. Avoid, at all costs, right angle bends or corners unless the blower picked for the job is more than adequate. A straight shot from blower to tube to vent is the best way to cool.
5. Take advantage of "convection construction" whenever possible; let the heat rise and not be trapped in enclosed spaces.
6. Bypass blower leads for minimum "hash" interference; use brushless type motors whenever possible.
7. The quieter the blower the better. Other hams do not relish hearing loud blower sounds modulating the carrier with vibration and mike pick-up.
8. Be sure to allow adequate screened opening for the air exhaust, to avoid building up unnecessary back pressure.
9. Use temperature indicators if in doubt of final tube temperature. Observe all safety precautions while measuring temperatures when final is operating.

Proper air cooling for your final will pay off in fewer breakdowns and more hours of carefree QSOs. Now—pick up your best blower and start building that favorite VHF rig.

. . . K9CNN



Top left to right, squirrel cage brute 1/6 HP, squirrel cage puller type (draws air into cage).

Bottom row, squirrel cage with "phono" motor (very limited cooling capability), and last the DC motor surplus special. This operates at 28 V DC, 1 amp. and 15,000 RPM. At half speed the noise is terriffic! Motor life due to brush wear is also poor. This type of blower produces much electrical interference and also requires a separate DC supply to operate it.

*Temperature indicating crayons are available from Thermochrom, Curtiss Wright, Princeton Division, Princeton, New Jersey. When the temperature of the crayon rubbed on the tube surface is exceeded the color changes. In no case should the tube temperature exceed the manufacturers rating, and any temperature above 250°C means trouble.

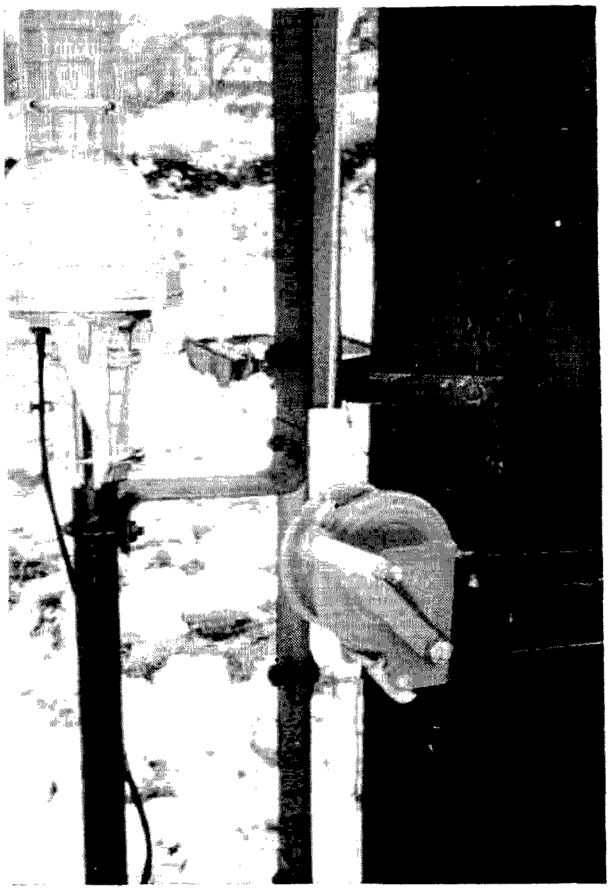
Dear Wayne,

How much tongue in cheek is involved in your de W2NSD/1 in January I don't know, but I like it anyway. The second paragraph on page 4 is a real honey. Please note that several channels on 20 meters have been occupied as you suggest for a long time. 14,336 is the Independent County Hunters Net. We are on 7 days a week, almost all day. We have a common interest and we really get along as good friends. On 14,332 is the International Single Sideband Net. They have a great comradship and even put out a lovely little magazine once or twice a year. Of course 14,340 is the CHC Net with ole K6 Bad Xample. When 50 or so hams, all interested in the same thing, gather on one channel together it leaves lots more room for individual QSO's.

Bertha, WA4BMC

A New Support for That Beam

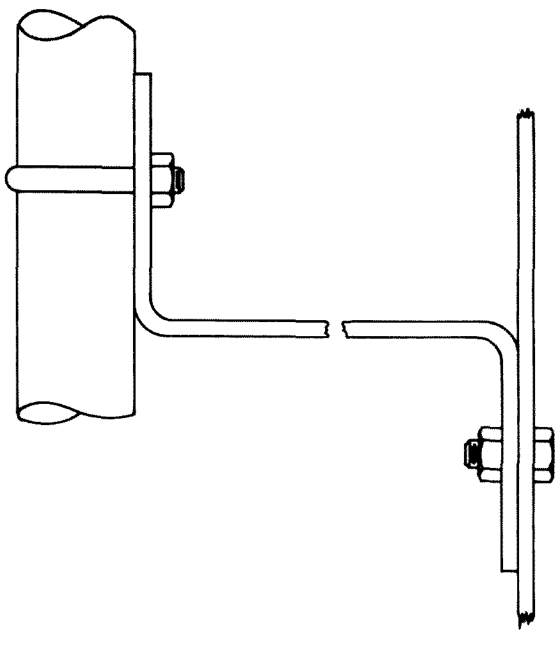
Peter D. Black K1MYV
Gage Hill Rd.
Pelham, New Hampshire 03076

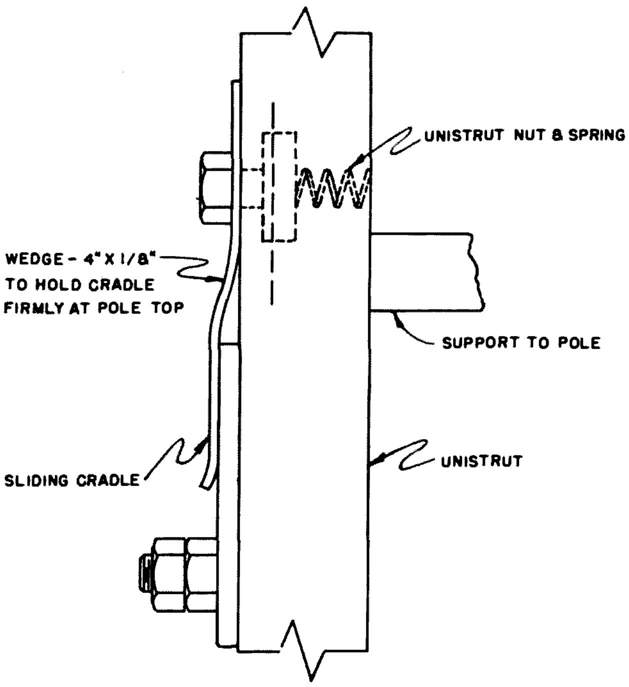


There is almost always more than one way to skin a cat, or even to support a beam, so here is what I believe to be a slightly different approach. Having reached the age of reason or cowardice, whichever you prefer to call it, my ideas were concentrated on bringing the beam down to me for adjustments or repairs rather than climbing up to it. Also being oriented, by reason of employment, to supporting wires on poles, my thoughts naturally turned to that method, so how to run a beam up and down a pole was the problem.

From somewhere I remembered that a product called Uni-strut looked a good deal like a track and was quite strong. Here's the result which has been through two full years with the beam in place, and has been raised and lowered many times with the greatest of ease. All the fabrication was done at a workbench in my cellar with only a portable electric drill (⅜") and the typical assortment of hand tools.

The attached picture and sketches are almost self-explanatory. The pole is a 45 foot, class 5, treated hard pine, which was obtained from a pole treating plant about ten miles away and delivered to the site by the supplier. I was permitted to pick out a nice straight one from the yard. The attachment of track, winch, etc. was done in my yard very close to the appointed place of setting. The track is standard Uni-Strut channel (1⅝ inches square) which came in 8 foot lengths. The brackets which attach the track to the pole are ¼ inch x 1¼ inch flat iron, bent to shape with a vise, and fastened to the pole with ⅜" x 2" lag screws. Sections of the track are fastened together with the same ¼ inch x 1¼ inch flat iron. The cradle which supports the rotator and slides up and down the track is ⅛ inch x 4 inch flat iron, again bent cold at the vise in the cellar. Bending of both the brackets and cradle pieces was accomplished quite easily by clamping the piece





in the vise and attaching a three foot piece of two by four to the protruding piece to be bent, using "C" clamps. The bends produced are square and sharp enough. Near the top of the track, a piece of the same 1/8" x 4"iron is attached to the face of the track and bent as shown to provide a slot into which the cradle is pulled up, thus holding the cradle tightly against the track at the top. This seemed necessary because the three bolts which hold the cradle to the track must be a little loose to permit the cradle to slide on the track. There should be one of the track brackets to the pole near this slot.

Above the top of the track, I mounted a pulley wheel of fair size (four to six inches diameter) attached to the sides of this track with the aforementioned 1/4" x 1 1/4" iron. I bent this in a loop over the pulley, close enough so that the steel cable over the pulley could not get out of the groove of the wheel. The winch, again mounted on 1/4" x 1 1/4" iron, fastened to the pole with lags, is a small boat winch, designed for 1600 lbs. pull, and picked out of the catalog of a famous mail order house. The cable is fine strand flexible steel rated at 700 lbs. breaking strength. The combined weight of cradle, rotator, and three element beam to be lifted is less than 100 lbs.

The pole was set about six feet in the ground after complete assembly but with the cradle and beam temporarily removed. The cable was in place over the pulley at the top. Lacking complete confidence in my own work, I did step the pole for climbing but have not had to go up yet. The steps are at 90° instead of 180°, as is customary, to permit the beam to clear coming down. In my case the control cable and feed line are supported at about 20 feet above ground on the trunk of a tree about 25 feet away from the pole, and a slightly slack loop maintained to the cradle when at the top. This permits the cradle to be dropped without disconnection of these feeds. It can be lowered only in one position where all beam elements clear the pole and steps in coming down.

Work out your own details of construction, gentlemen, and I'm sure you can improve on mine. Oh, I forgot to mention—you'll find it real cheap, if you don't count your hours of work in fabricating and assembly.

"What's the beef this time? Interfering with your TV reception again!"

The Case for the 1/2 Wavelength Feedline

R. T. Hart W5QJR
Omega-t Systems, Inc.
516 Belt Line Rd.
Richardson, Texas 75080

The antenna, one of the most important elements in a communications system, is often the least understood portion of the radio amateur's station. It has been demonstrated that many antennas, when correctly tuned, produce an increased efficiency of 10 dB or more in receive and transmit signal strength, compared to the amateur's normal tuning method of using a VSWR Bridge. These facts have become apparent in the number of inquiries and comments received by the author in the use of the Antenna Noise Bridge (73, October, 1967). The purpose of this article is to briefly describe the essential features of an antenna system and their optimization for maximum performance.

An antenna is basically a resonant circuit. For maximum performance it must be tuned to resonance for the same reason that the transmitter output circuit must be tuned to resonance. When the transmitter frequency is changed, it is standard practice to "dip the final", and the antenna resonant frequency should also be changed if maximum performance is desired.

The antenna is basically a series resonant circuit with a resistive component, as shown in **Fig. 1.** The resistive component is referred to as the radiation resistance. Maximum current flow will occur in the resistance only at the resonant frequency. The value of the resistive component is a function of antenna height, ratio of physical to electrical length (loaded antennas) and other factors. The resonant frequency is a function of the physical characteristics of the antenna and proximity to other objects. The major problem, when looking at the overall system, is that the antenna must be physically separated from the transmitter, hence the need for a feedline. This article is concerned with coax feedline. If an antenna tuner is used, this line is short and the antenna is virtually moved into the shack. The normal procedure for amateur antennas is to use a coax line length just long enough to go from the transmitter to the antenna, and herein lies the problem. If a random length of feedline is used and the antenna does not have the same radiation resistance as the coax characteristic impedance (nominally 50 ohms), the power doesn't get to the antenna due to losses in the mismatch and to radiation from the coax. For this case, the coax becomes part of the antenna system. On the other hand, if a half wavelength of coax (or multiple) is used, the effect of the coax may be disregarded. The coax itself is the equivalent of a series resonant circuit. When the coax and the antenna are connected, if the line length is proper, the antenna feedpoint is virtually moved to the transmitter end of the coax.

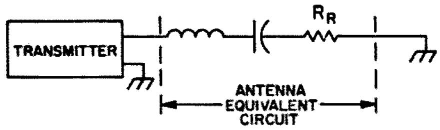

Fig. 1. Series resonant circuit.

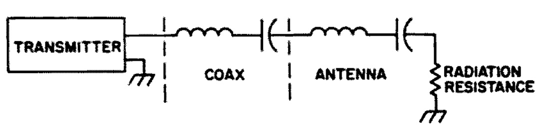

Fig. 2. Simplified antenna system.

With reference to **Fig. 2,** note that the entire antenna system can be simplified to the resonant circuit of the coax and the resonant circuit of the antenna, with the radiation resistance (feedpoint impedance) as the desired "load" for the transmitter. If the coax is a half wavelength long (or multiple), it effectively will be series resonant and thus a short circuit. If the antenna is also resonant at the same frequency, maximum current will flow in the radiation

resistance and hence maximum antenna efficiency.

If the coax is not a half wavelength, changing the length of the antenna can cause the entire circuit to be resonant, but the effect is to cause the coax to be part of the resonant circuit and hence radiation from the coax occurs. In addition, the antenna itself will not be a resonant circuit; hence, the resultant high impedance of the tuned circuit will prevent maximum current flow in the radiation resistance. This is not true if the antenna radiation resistance is the same as the characteristic impedance of the coax. Another effect is that the value of radiation resistance measured at the transmit end of the coax is not the same as the value at the antenna if the coax is other than ½ wavelength and the radiation resistance is other than 50 ohms.

The problem is aggravated by the fact that the antenna is resistive only at the true resonant frequency of the antenna. A few kHz from the antenna resonant frequency, the value of capacitive or inductive reactance reaches a high value for the antenna itself. Hence, the coax is no longer properly terminated, even if it were 50 ohms at the resonant frequency. The effective bandwidth of the antenna will be greatest if a matching network is used.

Most amateur antennas, particularly 80 or 40 meter dipoles and mobile antennas, have a low value of radiation resistance. These antennas will have low efficiencies unless a matching network is used to overcome losses in the antenna conductor. (See the ARRL Antenna Handbook.) Most beams use a matching network and are extremely difficult to adjust properly using a VSWR Bridge. The WSWR Bridge has the basic limitation that it cannot differentiate between resistive and reactive components. Most amateurs, not realizing this limitation, operate their antenna at the frequency of lowest VSWR, *which is not necessarily the same as the most efficient frequency.*

If a system is tuned using the following steps, maximum efficiency will occur:

(1) Use half wavelength coax, or multiple thereof, or locate the Bridge at the antenna feedpoint.

(2) Tune the antenna to the desired frequency.

(3) Adjust the matching network for 50 ohms.

If this procedure is used, minimum VSWR will occur at the frequency of optimum efficiency. If the coax is other than ½ wavelength (during tune up), the antenna is not properly tuned, or if the radiation resistance is not the same value as the characteristic impedance of the coax, minimum VSWR will not occur at the frequency of highest efficiency.

If the system is operating properly, changing the length of coax will not affect the VSWR reading. (Use ¼ wavelength coax for worse case measurement.) Thus, when adjusting an antenna using a VSWR Bridge, if the coax line length is alternately changed between measurements, eventually a proper combination can be reached. This is a tedious process and does not give an indication as to what to do to adjust the system. For this reason, an *rf* bridge is required to measure independently the resonant frequency and radiation resistance to allow tuning the antenna to the desired frequency first then to allow adjusting the matching network. Many *rf* bridges are available for this purpose, including the Heath Kit Antenna Scope, the Millen Bridge, General Radio Bridges, and the Omega-t Antenna Noise Bridge.

A mobile antenna, particularly on 40 or 80 meters, must utilize a matching network. The nominal radiation resistance is typically very low and when the system is operated at the frequency of minimum VSWR without a matching network, the resonant frequency will be out of band and the antenna will not give maximum efficiency.

The same comments hold for beam antennas. Here again, minimum VSWR does not necessarily mean that the antenna is resonant and the matching network is adjusted properly. Also, if a coax line of other than ½ wavelength is used, the entire system may be "down in performance" by many db.

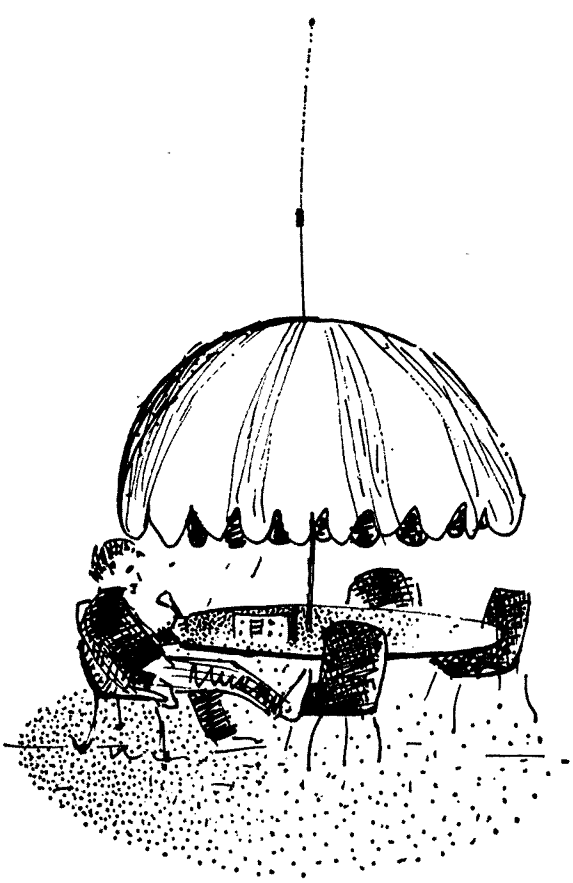
When using a multiband antenna, the coax length should be chosen for a multiple of ½ wavelength for all bands. Example: For a 10-15-20 triband beam a ½ wavelength coax on 40 meters (approximately 44 ft. RG-8U) gives 1 wavelength on 20, 1½ wavelength on 15, and 2 wavelengths on 10. If this is too short, the next length would be 1 wavelength on 40 (approximately 88 ft. of RG-8U) which gives 2 λ on 20, 3 λ on 15, 4λ on 10 meters. If this is too long,

it is better to coil up the excess in the corner rather than cut it off and not have the proper electrical length of feedline.

To achieve maximum antenna performance these considerations should be applied to all amateur antennas in addition to the normal choice of antenna type, height above ground, etc. These considerations do not rule out the case of using ¼ λ lines for matching networks.

As an example of the relatively critical tuning of antennas, the antenna conductor forms the inductive component of the tuned circuit. The capacitive component uses air as the dielectric, and the capacitive component is distributed along the conductor. If the dielectric constant changes, the resonant frequency of the antenna will change. Among other factors, the relative humidity of the air is influential. A 40 meter dipole has been observed and changes of 200 kHz in the resonant frequency are not uncommon from dry air to measurements made while rain is falling.

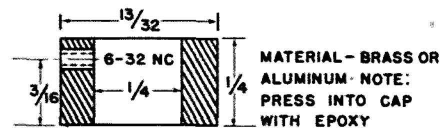
Before you purchase the linear, tune up the antenna. It's cheaper and the results will be about the same. Then, if you add the linear, the rest of the crowd will move over when you come in. . . . W5QJR



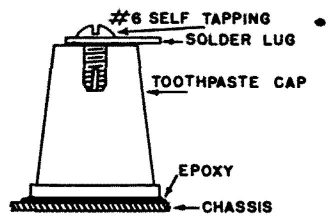
Putting Creativity to Work

D. E. Hausman VE3BUE
54 Walter Street,
Kitchener, Ontario, Can.

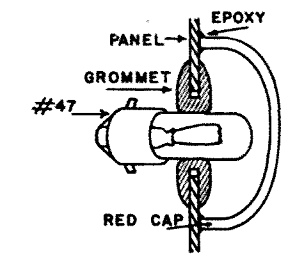
The purpose of this article is to show how the radio amateur can use his creativity for his benefit. As an example of what I mean by creativity, I shall describe several ways of using such common items as toothpaste tube caps and the like. In all cases it will be readily apparent that the cost ofconverting these inexpensive caps into useful and needed items is small, the conversion is easy and the new item is in some cases difficult and expensive to get commercially.



FERRULE FOR KNOBS



STANDOFF INSULATOR



DELUXE WARNING LIGHT

Stand-off insulators

Small caps, especially those from toothpaste tubes, can make dandy stand-off insulators. The diagram shows how a solder lug is held by a #6 self-tapping screw. More than one lug can be used if necessary. The completed insulator is attached by means of epoxy glue or similar adhesive. The use of these insulators is not recommended in high-voltage circuits for obvious reasons.

Deluxe warning light

Do you want your "warning" lights to command the attention they deserve? The cap from a detergent bottle, etc. will make a large dome that, when illuminated even by a #47 bulb, will command far greater attention than those small "jewels". It is perfect for the B+ pilot light in a linear amplifier or high power transmitter. A red cap will, of course, be best for this application. The diagram shows how the pilot lamp is held by a grommet and how the cap is cemented over the lamp with epoxy glue. A commercially available lamp socket can be used, however, at a greater expense.

Protective feet

And when you finish that new construction project, you will need some protective feet to protect your operating bench from mars or scratches. A common toothpaste tube cap comes to the rescue with no modifications. Simply glue these caps to the bottom of your project, and there you are. These caps are surprisingly strong and will support quite a heavy load.

Miniature knobs

Since the introduction of solid state devices, the size of electronic equipment has become smaller and smaller. If standard size knobs are used on such gear, there will be no room in-between the knobs for the fingers. Again, toothpaste tube caps can be converted into small knobs. The diagram shows how a brass or aluminum ferrule is made to fit inside the knob. Epoxy glue holds this ferrule securely. A hole is then drilled in the side of the cap and a tap is used to thread the hole. A 6/32 tap is a good size. The dimensions given in the drawing are "universal" and will work with nearly all toothpaste tube caps. The easiest way to make the ferrule is to use a lathe. If this is not possible, get some 3/8-inch brass from an industrial supplies dealer (look in the yellow pages) and after cutting the stock into 1/4 inch lengths, drill a 1/4 inch hole concentric to the circumference of the brass. In some cases, miniature controls come in 1/8 inch shafts and

suitably sized knobs are difficult to get. If you use homebrew knobs it will be no problem making this smaller hole. The set-screw is a 6-32 x ½ inch screw with the head cut off and a slot cut in the end with a hack saw. If you need an index line, take a toothpick and after dipping it in a bottle of India ink, darken one of the ribs along the side of the cap.

Although this may be redundant; get your wife to save up all the caps she gets. So there you have it; it's not that hard to use your head and come up with some mighty useful items.

. . .VE3BUE

YOUR CALL

Please check your address label and make sure that it is correct. In cases where no call letters have been furnished we have had to make one up. If you find that your label has an EE3*&* on it that means we don't know your call and would appreciate having it.

CLUB SECRETARIES NOTE

Your club can round up some extra funds by imploring, cajoling, convincing, or forcing your members to subscribe to 73 Magazine. Never mind the cries of anguish, just remember that you are doing what is best for them—and the club.

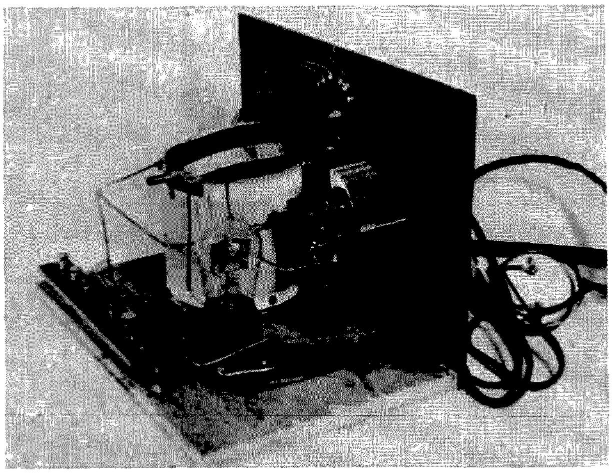
Subscriptions to 73 are normally $6 per year. The special club rate is exactly the same: $6. The only difference is that the club treasury holds 25% of the loot and sends the rest to 73. Send us $4.50 for each one year subscription, in groups of at least five subs. Just think, if your club has 10,000 members you can quickly get $15,000 for the club on this deal!

Send the subscriptions to us on 3"x5" cards, giving the name, call, address, city, state and zip code of each subscriber. If the subscription is a renewal please include the address label from a recent 73 wrapper. Indicate all renewal subscriptions so we won't start a second sub. We have been known to do that.

Send to: Club Finagle, 73 Mag. PETERBOROUGH, N.H. 03458

The Lamb Dyer

Ted Woolner WA1ABP
30 Cedar Rd.
Shrewsbury, Mass.



It's hard to start a story that many will not believe, but, I'll have you know, that better than half the lies I tell are true. This all started when I was studying to become a ham in 1963 . . . The teacher allowed as how it would be impossible for me to remember how to make a receiver such as I had made in 1921 when I was a "Child radio nut." We were all called "Radio Nuts" in them there days and we all made our own receivers and invented enormous lies about stations we had heard the night before. The red ears were not a sign of shame about these lies, but merely head-phone-itis. We loved our radios and here was a teacher that had the unmittigated gall to say I couldn't do it now!

It took a lot of time and a lot of attic searching but finally 1 had all the parts—including the U V 200 Radiotron detector tube! The work started. Being older and having a better supply of tools than a twelve year old country boy, it went along fast and the finished product, a one tube regenerative, using a vario-coupler tuned with both "Taps" and a variable condenser across it. One end of a tickler coil to the plate of the tube and the other end to the headphones created the necessary feed-back or "regeneration."—I was, again, a care-free boy of thirteen! That is the way I felt! Now, hook up the storage battery and the "B" battery, place the headphones (Brande's) on the head and slowly, with bated breath turn the rheostat on. Aaaaaah, the old tube lights up a little, turn it up a bit further—it glows brightly and the old familiar rushing sound comes out of the ancient ear-phones . . . By golly, it's gonna work! Flatten out the tickler, move the tuning dial and there is the old familiar whistle. Now, tip the tickler just to the breaking point of oscillation. There it is, a dance orchestra playing a number from out of the past—Lime House Blues! Gosh, it had been many years since I had heard that almost forgotten number. They reached the end of the number and the announcer said it was played by the Silvertown orchestra in Chicago! Well, this couldn't be, I must be imaginning that it what I heard, so I moved the dial a bit and there was a tenor banjo with another orchestra playing, "I'm in Love With You, Honey" . . . The announcer said it was Harry Reeser and the Cliquot Club Eskimos at W G I, Amrad, Medford Hillside! When would I wake up out of this dream—I blinked and swallowed hard—and whirled the dial to, believe it or not—Roxy's gang and little "Gamby" singing, "I've Got a Pain in the Sawdust—" . . . . . My hand was shaking and a voice from another station—yes, from a by-gone time said, "This is Jimmie Gallagher, still hangin' on"—W PG at Atlantic City . . . Next the Miami Beach Hotel—W M B H, then station at Fort Wayne. Holy mackeral, this was too much: I pulled out a cigarette and reached a shaking hand for my lighter on a shelf over the bench. Wouldn't ya know it, it fell from my grasp and hit the tip of the old U V 200 which slowly dimmed and went out and a small spiral of smoke issued out of the broken tip—or did it return to the bottle like the genie I've heard about? I don't know. I've never found another UV 200 and the later U X201A don't seem to do the same. True, I hear many stations on this old time home brew set but since that accident with the lighter—hmmm.

Accurate *if* Alignment

Harold Mohr K8ZHZ
5670 Taylor Rd.
Gahanna, Ohio 43020

I hear many hams talk of the troubles they have in accurately aligning the *if's* of their receivers, especially some of the newcomers using a converted surplus receiver. I have been using the procedure listed in **Fig. 1** for years, and find that most receivers will come close to reading correct if the *if's* are set correctly before any *rf* or oscillator alignment.

As all American BC stations use 10 kHz separation and are crystal controlled, I use them to check signal generator settings. For instance, suppose I want to align a receiver with an *if* frequency of 1680 kHz. Setting the signal generator at 420 kHz, its 2nd harmonic should zero beat with a broadcast carrier at 840 kHz. Then it fourth harmonic is within a few cycles of 1680 kHz, and is used for the *if* alignment. To align a 455 kHz *if* accurately, I zero beat the signal generator's second harmonic of 455 kHz against a 910 kHz broadcast carrier, and align from the fundamental.

This approach is very accurate, and the signal generator needs a 30 minute warmup before doing alignment work. If the receiver *if* is known to be far off, I do a rough alignment before using this procedure.

if Freq. of rcvr.	Sig. gen. setting	BC station zero beat at:	Harmonic beat with BC sta.	Harmonic for alignment
260 kHz	260 kHz	780 kHz	3rd	Fund.
262 "	262 "	1310 "	5th	"
266 "	266 "	1330 "	5th	"
455 "	455 "	910 "	2nd	"
915 "	305 "	610 "	2nd	3rd
1650 "	330 "	660 "	2nd	5th
1680 "	420 "	840 "	2nd	4th
1750 "	350 "	700 "	2nd	5th

Charlie's Broken Dream

The Defeatist Attitude

David W. Elbrecht WA8VST
8 Saint Clair St.
Norwalk, Ohio 44857

"Where's that garden rake?" mumbled Charlie. It was dark in the basement and he turned on the light. As the naked bulb flashed on. Charlie was momentarily blinded. Then his sight returned. "I must have put it back by the furnace," he answered himself.

Charlie went back by the furnace, near the hot water heater, and turned on another light, this one flourescent. Then he saw it. It returned to his memory again. There on the bench was that fifty watt cw transmitter, general coverage receiver, and speaker. Two coax cables snaked their way upward to the ceiling and out the hole drilled in the window casing. Charlie remembered.

He moved toward the operating position with care, as if approaching a friend after many years, unable to remember his name. "It sees like only a few weeks ago. . .," he mused. Actually, it was years. Charlie sat down, fingering the key lightly, sending out a series of CQ, CQ, CQ. "Pretty good fist," he thought.

Then he wanted to leave, but his hand was drawn to the switch of the receiver. Soon the sound of the 40 meter novice band reached his ears. "The rig still works. I wonder if I can still copy any code?" But he didn't try. Suddenly he was gripped by a feeling of nostalgia for this hobby that once was his. He tuned the receiver up from the novice band to the phone band. There they were: rag chewing, working DX, handling traffic, and there was a phone patch. Then Charlie looked at the vfo he was never able to use, right next to the home-brew modulator which received the same fate.

Charlie's thoughts wandered to the day several years ago when he went to Baltimore to take the general test. He was nervous then, but thought he could pass the exam. "After all," he remembered thinking, "didn't Joe up the street pass it? Why can't I?" But he didn't. He vowed to return in a month to try again. That time he really felt confident. Failed. What was wrong? He had thought about going back a third time, but he never gotten around to it. It was kind of embarrassing.

About a year after his novice license ran out, Charlie thought about selling his gear at one of the local radio club meetings. Somehow he just couldn't bring himself to talk to the fellows, though. It was like he wasn't one of the group. After all, if you don't have a license, you aren't a ham. He had often seen his dipoles for 80 and 40 meters hanging in the back yard and felt they should be taken down. But it was an all day job to climb up that tree again; the garage roof wasn't as sturdy as it used to be, either. The antennas weren't too obvious, so he just pretended that they weren't there at all.

So the rig sat in a dark, unused corner of the basement, hidden behind the hot water and some old snow tires so Charlie couldn't see it, just as his memories of his days on the novice band were relegated to some obscure recess of his mind, along with the dreams of a general ticket. But every few months, Charlie was drawn by fate to the basement where he was forced to remember.

Charlie stood up and viewed the scene. Dust covered logbook, dog-eared handbooks and magazines, cobwebs guarding the t-r switch, and a few crickets scurrying from the transmitter cabinet. Charlie turned off the receiver and shuffled away. "Now, where's that garden rake?"

(Kluge Tube)

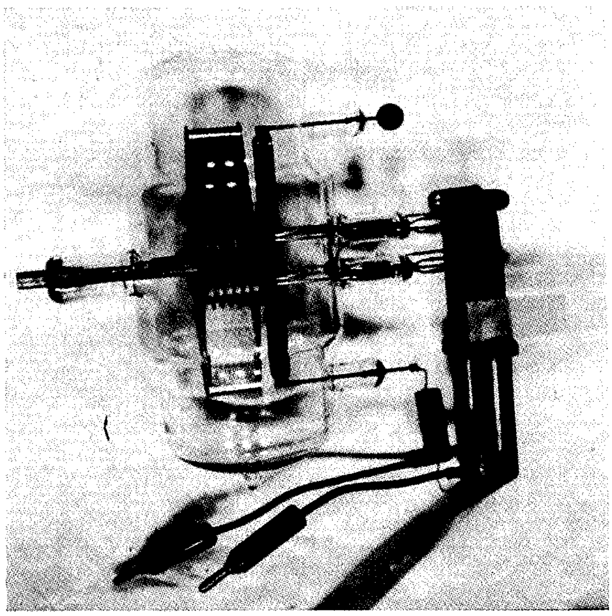

Fig. 1. The remarkable radar tube. From the dimensions of the quarter-wave lines that provide electrical and mechanical continuity, it appears this tube is designed to oscillate around 1200 MHZ. It comes with an 80-ohm grid resistor, far too low for amateur applications.

There is a term for something big, odd, and not very useful. I heard it recently; it is "kluge.' Since I am writing about a thing properly called a kluge, naturally this is a bit of kluge copy.

But hold on a minute . . . a good idea is still a good idea even though it may be out of date, or obsolete a few times over. See **Fig. 1.** Here is our kluge, and it certainly is one of the most awesome things I've ever pulled out of a big box.

This thing is a VT-158. Developed just before or early in WW 2, it is a UHF oscillator tube, with about two-thirds of the oscillator circuit inside the tube envelope. At peak powers in the 250 kw range and at frequencies in the order of 1000 MHz, the tube simply could not be constructed in an orthodox way. All that is a very interesting story, in which the development of the tube opened new technological fields, and the tube itself affected the course of WW2.

But what can you do with it now?

Maybe you can set it on your mantle as a conversation piece. (keep it away from children; it's full of vacuum and sharp edges) A museum might be interested, or it's a rather fantastic thing to look at. Something like reading a chapter of a book on high-frequency techniques. It's a lesson in itself to simply work out why this tube is built the way it is. But how about this?

Taking a fresh look, let's recall some vacuum tube theory. If we go to a lower frequency or think in dc terms for a bit, this amounts to one triode with the same amplification factor as any of the four triodes inside the envelope (since they are all similar) but with one quarter the plate resistance.

We will have to measure the plate resistance, but the mu is simply a measure of the effectiveness with the grid competing with the anode in controlling the anode current. A ballpark figure is available by looking at the tube; since the accelerating field at the heater surface is the sum of the grid and anode fields, and the grid is about three times closer than the anode, the mu is about two or three.

This tells us cutoff bias for class C operation will be terrific. At 800 volts on the anode, grid bias should be in the 400 volt ballpark. Remember we aren't using this as

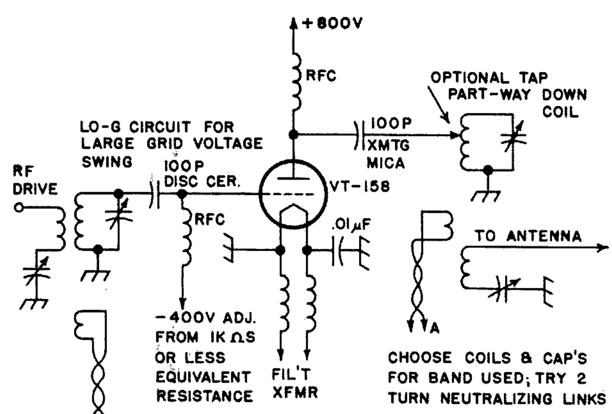

Fig. 2. Suggested schematic for an old idea power amplifier. Operating class C it should generate TVI as well as anything on the air, but it may be possible to operate linear quite effectively.

the manufacturer intended! That means we can use the same power supply for grid and anode, taking a little minus straight off the high voltage winding.

We don't want to try a really high voltage because with the greater heater area and fantastic emission capabilities (250 kw peak) the anode resistance is probably quite low once we've defeated the space charge. Can we make an amplifier out of this?

I think so. Its internal structure is a bit of an obstacle, and so we cannot use it in a tuned-line circuit. But on the lower bands the four triodes will get by as one, and you can even go to link neutralization again. Heater power is a bit high, but, after all, you can pare that down if you don't reduce the emission too much, and this old broadcast engineer's trick increases the life of the tube.

Anode dissipation is a big question. It is probably several hundred watts, and the grids can run approximately white hot, so should be durable enough in amateur service. Just keep on remembering those 250 kw peak power ratings!

A proposed schematic appears in **Fig. 2.** Remember, this hasn't been tried, yet, and is based largely upon an eyeball estimate of what the tube might do. Let us know how it works out!

The VT-158 is available from United Radio. See ad on pg. 61. ■

Amphenol Opens Up the Parts Market

As you walk in the door of your local parts distributor you may intend to buy a single component. But the distributor must bear many costs and wants to sell you ten or a hundred, all the same. This conflict of interest was resolved very nicely several years ago, by the idea of "amateur privilege." That is, anybody with a ham ticket in his pocket could go to nearly any wholesaler and pick up what he needed at wholesale prices.

Those days are gone. Discount stores selling to anybody who walks in the door, rising prices and costs, the advent of big money in the TV, hi-fi, CB and automotive electronics fields have jointly confused the idea of "amateur privilege" until at this point anybody under 30 or so probably has never heard the term.

Faced with competition and a growing consumer market, a few wholesalers and retailers have tried packaging as an answer to the sales problem. "Sell a pack of several; it's not hundreds but it's a sale which somebody is going to make" is the idea, and a bit of modern technology has provided an answer to the problem of inexpensively packaging things. The answer is the Blister-Pak.

Previous efforts have not been successful because the packages cost too much. But the Blister-Pak system has emerged as a fast, automatable system which packages items at the least possible cost. Prices need not be much above those of the fellow down the street who sells the same parts out of a dirty old box. And useful circuit data can be included in the package, compensating for the slightly higher prices and making up a very salable item.

The result of this new approach, which is based on two years of market research, is appearing in the form of rotating self-service racks in distributors' showrooms. If you need something, you go to the appropriate rack and choose what you need or a reasonable substitute, and when you're done shopping you make just one trip to the counter. This Blister-Pak idea is likely to prove a really big boost in the parts sales business, and will offer greatly increased convenience to shoppers.

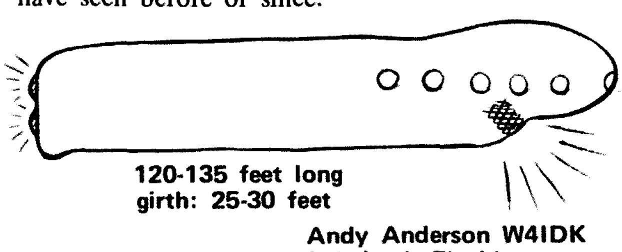
Amphenol is presently marketing 53 different blister-packaged components, including a variety of connectors, directed to the needs of radio amateurs, stereo and hi-fi fans, and even CB'ers. There are also audio adapters, and even in-line lightning arrestors, with more to be added later. Free hobbyist booklets, provided on the displays, are designed for handy workbench reference. For more detailed information, contact Amphenol Distributor Division, 2875 South 25th Ave., Broadview, Illinois 60153. ■

LETTERS

Dear Wayne,

On July 21, 1968 I was working on the 4-12 shift. I left Bartow, Florida to return home in Lakeland at about 12:15. This trip takes about 15 minutes at normal speed, so I judge that it was near 12:35 am when I got home. I parked at the house and stepped out into the drive to take a look at the weather. It was very quiet and I could hear a strange noise as if there was a sharp breeze coming in. I looked up in time to see the cause of this swishing sound. I saw a disc about 20-25 feet across traveling from south west to north east at about 100-150 feet up. It was inclined slightly lower on the forward direction with a slight tilt to the right. It appeared to be of a fairly bright metal much like annodized aluminum. It had a black or dark ring about 4-5 feet in from the edge that looked to be about 2-3 feet wide. I got a good look at it for it was not going at a high speed. There was no other sound than the wind caused by the passage of this object through the air. Had it not been so quiet I would not have been able to hear it at all. There was no light coming from it at all, but it was plainly visible in the reflected light of the street lights. Apparently I was the only person to see this one so I can only give an unverified report on it.

I can give a verified report on an earlier sighting together with a drawing made by the four people at the time. I was the manager for the Bordon plant in Lakeland and attended a sales meeting in Clearwater with my office manager, sales manager, and the supervisor from the plant. When we were driving back we saw a very bright blue light approaching from the east. It appeared to be coming lower and the light got very bright. There was a very bright full moon and the road was almost empty of cars. As this object appraoched we stopped the car, shut off the motor and got out. It passed about 500 feet south of the road at an altitude of 500 feet. I could plainly see the curved band of very bright blue light just aft of the nose on the lower front. A series of very bright portholes extended at midpoint of the body and appeared to go completely around the nose. There were two pale glowing domes on the rear of the body. This object made no noise at all and THERE WERE NO WINGS. It passed between us and the moon. Our observation point was between Tampa and Plant City on what is known as Dover Flats. As we watched the object which was traveling very slowly (perhaps 20 mph), it speeded up and disappeared in just a few seconds. We decided to each draw what we had seen without discussion. Below is the drawing as it appeared to us. Our estimates were very close. I have seen many odd shaped planes and blimps, but this was nothing like anything I have seen before or since.



120-135 feet long
girth: 25-30 feet

Andy Anderson W4IDK
Lakeland, Florida

Dear Wayne,

Very seldom do I write a letter to anyone, especially to thank them for a service rendered. The service I am thanking you for is the much enjoyment 73 has provided me over the past few years. I take all the popular amateur publications and I must say that 73 is by far the best. It seems as if the articles are very timely with projects I would like to build or information that I need on one of my own ideas. Just keep up the good work and print what hams want to know.

Bob Budsong WA4SLG
College Park, Georgia

Dear Kayla,

Sorry, but just hafta send another one of those nice letters! 73 was the first publication that I got acquainted with after getting my Novice, although I had seen the others. I really appreciate 73, both editorially and technically. I realize that thousands of readers have a like number of ideas or desires, but I like the basic policy that 73 is for us and not trying to establish some kind of ecclesiastical headquarters. My two desires are that you continue to keep us advised as to what is pending in ham radio and stuff that we can read and build in order to advance ourselves. My only complaint is that 73 comes only once a month and should be twice as large! Hi! One other comment: whatever you do for the Novice and new General now will be remembered when we are Extras. Thanks so much for the efforts of the staff.

L.E.Thompson
Eau Claire, Wisconsin

We could publish twice as many articles if the advertising would support it. It is entirely up to you, the readers, to impress on the manufacturers and distributors that you are looking for their ads in 73 and not in the other magazines.

Gentlemen,

I wish to take this opportunity to compliment the entire staff of 73 Magazine for their efforts and dedication to Ham Radio, by the absolutely excellent series of articles, "Getting A Higher Class License." These articles have helped me personally and I'm sure untold thousands of other Hams in really understanding the "hows and whys" of our equipment. Keep up the good work.

James Hall WA8SED
Miamisburg, Ohio

Dear Wayne:

To kill some time, I happened to page through "The Index to Articles Appearing in 73 Magazine in 1968." Articles such as "Tuning in on Bonadio's Satellites," "An Invisible Antenna," "How to Write for Service Information," "I Rode With the (excuse the expression) CB's," and "A Space Communications Odyssey" really turned me on. In my mind, these types of articles are the ones that make your magazine very worthwhile and interesting. However, to keep you from getting a big head, I feel your construction articles usually are somewhat in left field, and I'm an Extra Class ham that likes to homebrew things.

Leland L. Bahr, W9DRC
Park Forest, Illinois

Open Letter

The annual ARRL Board meeting will be held in May. It is now time to advise your Director of your wishes regarding matters to be acted upon at this meeting.

There is an international telecommunications conference scheduled for late 1969 or early 1970. This meeting concerns the UHF/VHF. It is expected that all amateur bands in that spectrum will come under extreme scrutiny and perhaps some drastic changes (or possible losses) will result.

It is of vital importance that the usage of the UHF/VHF be increased, and that the results of amateur communications on these bands be widely publicized, in all media. This is the year of VHF/UHF if we expect to hold these frequencies now allotted to us.

It may be already too late, but the effort must be made by ARRL and the amateur body.

Probably the most effective demonstration of these frequencies can be made thru EME communications. This 1969 ARRL Board of Directors should act to place ARRL in the strongest possible position in this vital field of amateur endeavor. This 1969 Board must act, and quickly!

In 1967, the ARRL Board allotted the piddling sum of $1500 for an "ARRL Space Station." This ridiculous amount for such a worthwhile and necessary project is actually an insult to the fine VHF/UHF work being done by others.

ARRL should appropriate whatever is needed, even if it costs a hundred or more thousand dollars, to equip and to staff an adequate EME ARRL station--if ARRL is to live up to its self-appointed role of leadership in amateur radio.

ARRL must have such a station now to help others in this work and prove that ARRL is actually interested in UHF/VHF work. ARRL's attitude toward these frequencies has been less than enthusiastic in recent years.

A state-of-the-art, legally-powered EME station operated on a 24-hour basis by ARRL would surely focus attention on these activities and would serve all amateurs world-wide in their efforts on EME--if only to listen to ARRL's EME station, such as many do to W1AW.

It is pathetic that ARRL with its many kilobucks in stocks and bonds has not already acted to build and staff an adequate EME station. However, it appears that ARRL Board action will be necessary to force HQ into action (there has been no visible result of their 1967 directive) to put ARRL into the VHF/UHF field. Such ARRL participation, long overdue, should be immediate and totally effective--and 1969 is the year to do it.

It is typical of ARRL HQ disinterest and lack of action that most of the marvelous work done on EME and other significant VHF/UHF work has been done by individuals or small groups without vast monetary resources, such as the ARRL has available.

The 1969 ARRL Board should take action to force HQ to support the NASTAR project (to place a ham station on the Moon on the first or second manned landing) which has NASA approval. ARRL should contribute money (in substantial amounts), as well as technical and publicity aid to NASTAR. (Note: There is no reason why it should require Board action to get HQ to do such things, but since it does--it is up to the Board to take whatever steps are necessary.)

If the ARRL Board does not take action (1) to provide funding for a meaningful ARRL EME facility (2) to provide substantial monetary aid and support of NASTAR--then this Board will be shortchanging the ARRL membership and amateur radio. If ARRL is ever to take a positive stand on VHF/UHF, it is now, 1969. And, this Board must see the job done properly!

Second only to the ARRL Space project is the long-overdue staffing of an ARRL's Field Representative department. This was ordered done by a past Board but nothing has been heard of this directive since. There is a vast gap between ARRL HQ and the ARRL membership (in personal contacts) and an even wider credibility gap exists between ARRL and non-member amateurs. This gap is widening.

ARRL HQ (through Board action, if necessary) can subsidize (through partial or total payment of personal expenses) the attendance of incumbent and former ARRL elected officials such as SCM's, directors or vice directors, at every ham gathering from a local club to a hamfest or convention.

An ARRL representative must be present to officially "show the flag" at every type of gathering where amateur radio and ARRL should be discussed. There are plenty of incumbent or former ARRL officials to handle this, and they should be accredited and equipped to do so. These ARRL Field Reps could collect information to be passed on to HQ or the respective ARRL officials, they could pass out ARRL literature and in general "pass the word" regarding ARRL.

At the SAROC in Las Vegas this January, there were over 1000 persons registered from 33 states, Canada and even some DX. The Pacific Division ARRL Director was present, circulated around, and held a meeting which was listed on the program. There was no ARRL booth or recognition on the display floor of ARRL or QST. ARRL QST was conspicuous by its absence in the presence of well-staffed booths operated by 73, CQ and HAM RADIO, plus QCWA, OOTC and MARS. There were no ARRL publications on sale at SAROC. The other magazines had elaborate displays and material for sale.

There are far too many licensed amateurs today who have little or no contact with ARRL. They do not even subscribe to QST, nor care about ARRL! They are ignorant of ARRL and it is ARRL's fault in that it is not officially represented at all ham gatherings.

What can you do about these matters? If you agree that something should be done--write a letter to your Director and send copies to your Vice Director and to ARRL HQ--attention Secretary. Request that your Director-representative take every action necessary to secure the adoption and success of these two important features--in 1969.

Also, request that your director second or support measures brought up by other Directors at the Board meeting that will lead to a more progressive attitude and total effort by ARRL and ARRL HQ.

A recent check at 73 revealed that only three of the sixteen ARRL Directors subscribe to 73 Magazine so it is necessary for you to call these matters to their attention. Editorials in QST repeatedly state that the Directors are "your representatives and that they welcome your suggestions." If this is true, and you make requests concerning this, then some action should result at the 1969 Board meeting that will be meaningful.

A. David Middelton, W7ZC
Former ARRL Director

... more Letters

Dear Miss Bloom and Mr. Green,

Since you have accepted an unsolicited article submitted by me, I hope that you will also accept this unsolicited compliment. The speed with which you reviewed and came to a decision upon my piece is something amazing in the annals of publishing. Needless to say, I consider your payment more than adequate and perhaps about twice what the article is worth. Your timing was perfect, as earlier in the day your check arrived I had committed myself to a new transmitter. The article won't pay for it, but it does make a tidy down payment on it.

Again, thanks for your prompt consideration and decision. I shall probably submit something in the future when I feel I have something to say and shall look forward to your efficient editing, even if you have to tell me it isn't worth its weight in sand.

L.B.Cebik, W4RNL
Athens, Georgia

Dear Wayne and Kayla:

I don't know if the shortage of articles on FM is due to a lack of editorial interest, or a lack of contributors. I personally think that FM as a mode of operation and things like repeaters will be the salvation of the ham world above 30 MC. At the N. E. Michigan hamfest, I attended an FM talk which included a slide show and recorded tape presentation about the Tulsa Repeater. As a ham who, until recently, has had little or no use for the VHF and UHF bands, I was astounded with what the Tulsa group had accomplished.

The recently formed "Great Lakes Repeater Association" has (or will shortly have) a repeater for the metropolitan Detroit area members. I recently obtained a Motorola 2M FM rig, and find that there is more to it than bolting it in and hooking it up. There is not a lack of talent in this area for putting it in operation. I expect to have it in operation soon.

But what about hams in other areas? How about a two or three month series on "Basic FM Theory?" True, there are conversion and schematic digests available from various sources, but they cover specific pieces of surplus gear. They are sadly lacking in basic information which applies to all FM gear.

So may I suggest a few basic articles on FM theory, or at least a few questions and answers in the staff articles on getting the higher licenses. It would be a step in the right direction, and another chance to get ahead of QST!

Keep the fine magazine coming every month.

Ralph O. Irish, Jr., WA8GDT
Utica, Michigan

(Authors take note)

Dear 73 Staff,

I was fortunate to have several of your 73's available to me with the study guide for higher class licensing. By using them along with other material, I did pass the Advanced test with very little trouble. I cannot praise your articles enough. They are written in a language that even I, a common housewife, can understand. I especially appreciated the humor along with the serious. I thank you very much.

Lyla KL7CSR
Spenard, Alaska

Dear Madame,

On or about January 1, 1969, the premises of the Grumman Amateur Radio Club were broken into and the following listed equipments were stolen:

Collins 32S-1 transmitter, Serial No. 10891
Collins 75S-3 receiver, Serial No. 10779
Collins 312-B-4 station control, Serial No. 52496

Publication of this information will be appreciated. It may be instrumental in the recovery of the loss. Please notify the undersigned or the authorities of any information leading to the recovery of these items.

Emmett Goodman, Sr., WA2JFA
Grumman Amateur Radio Club

Dear Wayne,

Just a note to applaud your suggestion of a UFO net! Ham radio has needed something like this. If this doesn't get picked up and something done about, we'd all better become CB'ers and give our ham bands to the highest crass commercial bidders.

Waldo Boyd
Geyserville, California

ODE TO A HAM

I notice when some fellow dies
No matter what he's been
Some saintly chap,
Or one perhaps
Who's life was stained with sin
His friends forget the bitter words
They spoke but yesterday
And now they think of a multitude
Of pretty things to say.
Perhaps, when I am laid to rest
Someone may bring to light
Some noble deed
Or kindly act
Long buried out of sight.
If it's all the same to you, my friends,
Just give to me instead
A clear frequency while I'm living
And the QRM when I'm dead.

Pete Fragale W8AEN
Clarksburg, W. Va.

UFO BOOKS

UFOs: A New Look, published by NICAP. This book gives dozens of well documented recent sighting cases and tells the inside story of the Condon "whitewash" report. If strange little men in "space suits" are not visiting our planet, then a lot of reputable people have suddenly made up similar tales in many parts of the world. Absolutely fascinating book. $3.00 in U.S., $4.00 foreign. NICAP, 1536 Connecticut Ave., N.W., Washington, D.C. 20036.

The UFO Evidence (1964, 128 pages). Published by NICAP at $5 U.S. and $7 foreign. Hundreds of carefully researched UFO sighting cases. This is the definitive book on UFO sightings by responsible observers. Can anyone remain a sceptic after reading this report?

The UFO Investigator, a newsletter published bimonthly by NICAP. $8 per year, including membership. This is the most unbiassed report on UFO sightings and events. Each issue is worth its weight.

Projects Grudge & Blue Book Reports (USAF case histories and analyses) published by NICAP. $5 in U.S. and $7 foreign. One can only ask how, with reports like this to work from, our Air Force can pretend that UFOs aren't there.

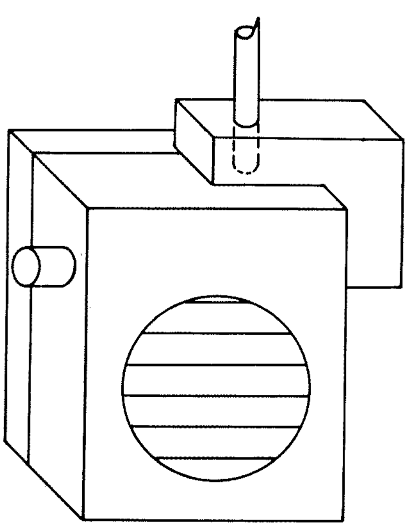
For Those Who Think Small

and Other Hints

David B. Cameron WA4VQR
324 S. Riverhills Dr.
Temple Terrace, Fla. 33617

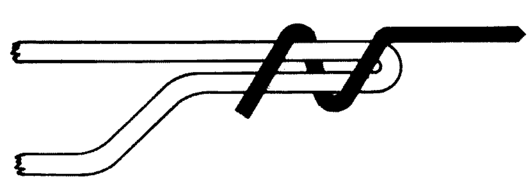
Hams have found that "walky-talkies" can be converted, with a little Yankee ingenuity, into low power 10 meter mobile units, transmitter sniffers for hunts, monitors, and other similar gear that doesn't need much punch. A popular source of these mini-rigs for the money minded ham has been imported oriental gear that can often be bought on special sale for as low as five bucks a unit. Unfortunately, many of these units share a common structural flaw. In an effort to produce the units as cheaply as possible, many manufacturers have the antenna screw in at the top. For the ham who parks his gear in the shack all day, this is fine, but the poor fellow who takes his out may find that that long light antenna grabs for trees and bushes like they were home. The next thing he knows he has an antenna broken off at the bottom or a plastic case cracked where the threaded antenna receiving piece is attached. All he can do is mutter that God shouldn't have made trees, electronics, or the Japanese. There is something that can be done before this happens (or after if you're really stubborn). Take a piece of plastic, ¾" thick, cut it as shown in **Fig.** 1, and drill the required hole where the antenna will fit. The antenna support will help some if just set into position, but will be stronger if cemented there. Two things to watch, the distance from the antenna to the side of the unit must be measured accurately to insure a good fit, and the hole for the antenna must be large enough to allow a sliding fit without much play. This may mean that if your antenna is an odd size, you will have to drill a small hole and enlarge it with a rattail file. Now, on the other hand, if you want a beam antenna, you're on your own!

. . . WA4VQR



Soldering Tip Top

One of those necessary parts for the ham shack that is hard to remember when you are in the parts store is a new soldering tip. Like many hams, I have, for a long time, used short scrap pieces of large diameter bare copper wire (#10-#14) instead of commercial soldering tips. With the invasion of transistors in ham technology, I was faced with the choice of either burning my fingers with one of these constant heat soldering pencils or overheating the components with my large gun because the tips were too big and too hot for the circuits. I solved the problem by making tips with # 12 wire, then taking about a two inch length of the same size wire, wrapping half of it around the end of the tip and leaving the other half protruding. This forms an indirectly heated tip, with a lower temperature that can be varied by adjusting the length of the single wire that extends beyond the end of the loop, just as the temperature of the old-fashioned electrical soldering irons is controlled by sliding its moveable tip in and out. The tip can go into the smallest circuits, but won't sit on the bench smoldering when not in use.



David B. Cameron WA4VQR

A Report on the WTW Award

Since Gus is leaving for another DXpedition soon, Dave Mann K2AGZ will be the new custodian of the WTW. Files are in the process of being transferred at this time. Address all WTW correspondence to Dave at 1 Daniel Lane, Kinnelon, N.J. 07405

Gus Browning W4BPD

For those of you who are not familiar with our WTW rules. In brief they are basically:
1. All QSO's must have been since May 1, 1966, 0001GMT
2. All QSO's must have been on one band & mode (SSB, AM, NBFM all considered phone)
3. Separate WTW Certificate for the following:
   a. 100 countries on CW-28Mc WTW-100-28 Mc CW certificate
   b. 100 countries on Phone-28 Mc-WTW-100-28 Phone certificate
   c. 200 countries on CW 28Mc WTW-200-28-CW certificate
   d. 200 countries on Phone 28 Mc WTW-200-28 Phone certificate
   e. 300 countires on CW-28Mc WTW-300-28-CW certificate
   f. 300 countries on Phone-28Mc-WTW-300-28Mc Phone certificate
   h. 350 countries on CW-28Mc WTW-350-28Mc CW certificate
   I. 350 countries on Phone-28Mc WTW-350-28Mc Phone certificate
4. You can qualify for the above certificates on each ham band. But I have my doubts how long it will take someone to qualify for that WTW-350-CW on 28 Mc! But it is possible for a real go getter to earn, lets say, 4 certificates on 10, 15 and 20 meter bands.

In looking over the claimed scores that are being submitted to me for our honor roll I can see the interest building up in quite a number of different bands and modes. With the very FB conditions on the various bands I can see a number qualifying for their next higher WTW award—One certain fellow is getting very close to WTW-300 and I think he probably will have the cards on hand by next month and a couple of other stations are just behind him, so you see fellows—it's possible to make WTW-300 in just a little over 2.5 years of operation and "going after" QSL cards.

Any of you DX stations let me again remind you that there are many W/K stations that would like to become your QSL manager and many of these QSL managers actually pay to have your QSL cards printed themselves. The idea of DX stations getting a stateside QSL manager should solve the problem of QSL cards once and for all time. So pass the word around to your DX friends and tell them the many advantages of having a QSL manager. This would automatically eliminate the burdens of QSL's to those who have trouble with both money and time in sending them out.

Great starts here for some very interesting battles in DXING. If I have your score wrong please drop me your latest CLAIMED SCORES—not QSL cards—BUT WHEN you hit the next plateau in the WTW then you are to submit QSL cards to your WTW QSL check-point—if no point send them to me.

We now have a WTW Check point for W2/K2 land: Peninsula Amateur Radio Klub, Foot of 25th. Street, Veteran's park, Bayonne, New Jersey 07002.

MAIL ADDRESS: P.O. Box 531, Bayonne, N.J. 07002.

Still looking for a good Club in W1/K1 land—How about it fellows? Next month we will give the whole list of WTW check points.

. . . W4BPD

(...de W2NSD/1 continued from page 4)

amateur radio has been stifled, the country has suffered tremendously from a lack of engineers and technicians and has found it difficult to develop their communications and electronics industries.

In numbers we have strength and we need that strength badly. The time is drawing near when we will have to either fight for our frequencies or else watch them dwindle away as they have in the past. The time is here right now when we must organize our effort. What would our bands be like today if earlier amateurs had only made an effort to hold our allocations? Through complacency and laziness our "leaders" managed to lose 70% of the 40 meter band and 65% of the 20 meter band. Both of those bands used to be a megacycle wide, you know. They were given up without a battle and look at the mess that is left of them today!

What Can Be Done?

Every amateur who has the interest to try and help can do something to keep us from losing more frequencies. Something can be done right now, today! As a matter of fact, a month from now may well be too late. If every reader of 73 got on the air and talked one or two more amateurs into helping, the result would be a wave that could not be ignored.

If we are going to get amateur radio back into a growing institution we must make a major effort to interest more youngsters in our hobby. We need growth. We need to sell high school students on the fun of ham radio. This can be done in several ways.

First and foremost we need a strong campaign of national public relations and publicity. We need to have articles telling about the fun of ham radio appearing in Life, True, Look, Playboy and other national magazines. There are plenty of good ham writers and a wealth of material; all that is needed is one good man with PR experience and connections to organize the project. A good man will not be inexpensive, of course, and this means that an investment has to be made.

Perhaps you feel as I do that national publicity for amateur radio is a responsibility of the ARRL. They have the money right at hand to fund the project. They have the PR material at hand. They would seem to be the logical organization to work for the growth of ham radio. If this seems reasonable to you then why not get in touch with your ARRL Director and tell him that you want him to see that the League sets up a PR man or company to promote amateur radio. This is a very good time to dip into that over a half million dollars that is just sitting there in the bank and make it work for the survival of our hobby.

The next Board of Directors meeting is in early May, so you have only a few weeks to make yourself heard by your director. You actually only have a few days because your Director is supposed to send all proposals that he is going to make to HQ 60 days or more before the meeting. There is only one Board meeting a year so if you put off getting in touch with your Director for a few days then it won't make much difference and you will have lost your chance to have your say and make things happen

Perhaps you are not an ARRL member or the chap you work on the air turns out not to be a member. This is indeed likely, since only about 30% of the amateurs are ARRL members. This makes no difference. You can still have your say. Check in QST for the name and address of the Director of your area and call him or write to him and tell him that you are not a member, but that if you get the action you want, that you will think a lot more about becoming a member. Everyone works a lot harder for the dollar he doesn't have yet, believe me. The League is hurting and hurting badly for members. I think they will listen to you.

Writers like Jean Shepherd, K2ORS, who has won the Playboy prize for three years running for humor, could be egged into writing wonderful articles extolling amateur radio. But someone has to organize the effort and see that the stories and articles are placed where they will do the most good. Bandel Linn, K8LAP, who has done cover cartoons for us and occasionally scabs a cartoon for QST, is a nationally known cartoonist and could turn out ham-oriented cartoons which would help make ham radio a household word.

One good PR man with a reasonable budget could change the direction of our growth chart from the disasterous to the unprecidented. The ARRL Directors have for years been putting money aside for a rainy day. Is it going to get much more rainy than it is right now? If they just spent the money

their nest egg *earned* each year for PR things would spurt ahead. The stock market, on the average, has been advancing at about 12% per year for many years now. 12% of $575,000 (last reported ARRL statement) would give $69,000 per year.

The money is there to use and now would seem to be one of the best times to use it. The question is, can you talk your Director into getting off dead center and getting this money working for ham radio? It is up to you to move your Director. Call him. Write to him. Talk to him if he sticks his nose into a club meeting in your area. Put on the pressure. And if you don't get some action, give serious thought about getting someone into the position next year that will listen to you. With just a little interest and effort on your part you can make things happen.

Washington Office

For many years I have pointed out that amateur radio is weak because we have no representation in Washington. We are so far out on the FCC organization chart that most Commissioners are not really aware that we exist, much less are important. When the Incentive Licensing proposals were sent in by the ARRL and hundreds of amateurs went to the trouble of writing in their opinions of the action to be taken, how much consideration did we get? The League Board wrote to the FCC asking for "leadership and guidance" and what did they get?

We got just what we paid for and deserved. We got shrugged off. Our problem was farmed out to someone who knew little of our problems and who, apparently, cared less. There is no sign that the hundreds of comments filed on Docket 15928 were even read or noted. The end mish-mash was an amalgam of the RM's filed and reflected little of the comments on the RM's.

The services of an attorney to file proposed rule changes with the FCC are needed and we have them in the body of the ARRL Counsel, W3PS. But amateur radio needs more than that. Far more. The seat of power in our country is in Washington and the seat of power in Washington is in Congress. The FCC works under the direction and funding of Congress and don't think that one person on the FCC staff forgets this for a minute.

The system that is being used for getting action in Washington now is one that works and works well, whether we approve of it or like it or not, and that is the lobby system. Any group that has a common interest that they want to seriously protect goes to the trouble and expense of having someone represent them to Congress. Most hobby groups that depend in any way on government legislation or direction have a strong lobby working for them in Washington.

You know very well about the work that the National Rifle Association has been doing. You have undoubtedly heard about the Aircraft Owners and Pilots Association. I remember a few years back when AOPA decided that they wanted a law made so that foreign pilots could use their radios when in the U.S. In a matter of weeks they had the new legislation through Congress. It took us years and the personal friendship of Barry Goldwater to get a similar bill through for ham reciprocal licensing.

Lobbying is tightly controlled by law and it is highly illegal for the ARRL Counsel to lobby for amateur radio in Congress. We need a registered lobbyist in Washington for our own protection. We don't need anyone terribly expensive. There are probably dozens of hams in the area that have had many years of experience in working with our government that would be proud to work in our behalf as lobbyists. I know that if I had managed to round up something on the order of $20,000 a year with the Institute I could have had someone working full time for us in Congress and also with the other government agencies that influence our future.

The next ITU frequency allocation conference is coming over the horizon and there are a great many things that amateur radio should be doing in preparation. One of the key points of pressure at a conference such as this is a solid U.S. delegation. This means that the delegates from our country must have orders from their agencies that amateur radio is to be protected. We did not have this support at the last conference. Amateur radio was *last* in line for frequency protection. Oh, there was a lot of beautiful oratory about the value of amateur radio, but when it came down to who got what in a frequency exchange, we came last every time. If we have Congress behind us you can bet that our order of importance will be much higher.

What *Can* Be Done?

Tell your ARRL Director that you and

your club want him to see that the League opens a Washington office, even if it is in the bedroom of a local ham. Tell your Director that you want to be represented in Congress. Tell him that you want action now, not a study of the feasibility or any other put-off. Point out to him that all of the other users of radio frequencies are in there putting on the pressure not only to hold what they have, but to take as much of our channels as they can.

Explain to your Director that with everyone else pushing against us and us not pushing back, there is only one way that things can go. Let him know that you remember that this happened to us before in the past and that despite repeated assurances that everything would come out all OK, our amateur bands were cut to shreds. Ask any old timer what it was like when they lost the major portions of 20 and 40 meters.

Remind your Director that at the last ITU meeting in 1959 most of the nations of the world officially requested serious cuts in our amateur bands and that only a most remarkable circumstance enabled us to put off the day of reckoning. Remind him that since that day the Asian and African countries have gained control of the ITU and they are not amateur radio oriented. Remind him that India requested that the amateur radio bands be reduced to 20 kHz width. Tell him that the time is here, right now, for him to speak up at the Directors meeting in May and demand that amateur radio have a lobby in Washington.

The ARRL is the *only* organization you have. You decided that it should be this way when you supported only one organization. Now make that chosen organization work for you. The Directors are supposed to run the ARRL and make the decisions. You are supposed to guide the Directors in their actions. Guide... be heard...get action.

SAROC

After hearing how much fun everyone has had in the past at the SAROC Convention in Las Vegas, I decided that I'd better throw caution to the winds and make the trip. It turned out to be true...I did have fun. So did Lin. We laughed ourselves silly at Buddy Hackett and his dirty jokes...Lin won a few dollars on the nickle machines...I lost it back on the crap tables. We wandered all around Las Vegas, gawking at the giant Freudian extravaganza signs, unable to identify at all with the flashing lights and plastic. We got furious at the Brooks Rent-A-Car...oooooh, those scoundrels!

The Convention was nice. I got a chance to talk with a few old friends and sold a few subscriptions. Everybody there turned out to already be a subscriber.

On the way back to New Hampshire we stopped off at Aspen, Colorado for a little skiing. I do believe that they normally have the best skiing conditions in the world there at Buttermilk Mountain. Aspen is an old mining town and the prices are mining town prices. They have more top notch restaurants per capita there than any place else I know, so perhaps it is worth the price. We skiied all day, soothed our sore muscles in a sauna in the evening, ate luxurious dinners and had a wonderful time.

Back in New Hampshire we found the ski slopes worn to ice and dirt patches, the inserting machine for renewal notices jamming, the furnace out, the plumbing frozen, the offset press on its last legs, and other normal catastrophies.

Your Club

The club code and theory classes probably need a lot more customers to keep busy. Where to get them? The obvious place is the local high school. You can interest fellows in joining the club and learning about amateur radio by inviting them to come to your club meetings. Have one of your club members in the school put meeting notices on the school bulletin board asking all interested to come out to a club meeting and learn more about amateur radio. And don't forget to offer refreshments.

Not all CB'ers are bad people and you might do well to get the club members who have CB rigs to check the channels for good prospects to come to club meetings.

Once you have interested newcomers in coming to your club meetings you must do all you can to make them welcome and make arrangements for them to quickly get to know more about our hobby. Have members with good stations invite them over for a demonstration. Show them some phone DX work, some VHF, and perhaps some RTTY. Let them see some of the gadgets that your members have built.

Once your club gets into the swing of interesting new blood into our hobby, more and more ways will develop for getting interest stirred up. Pass along the ideas through the pages of 73 so everyone can benefit.

.....W2NSD/1

Rules for the 1969 I.A.R.C. Propagation Research Competition

(A DX Contest with a Purpose)

CONTEST PERIODS: This year the contest will be run in two sections. CW/RTTY from 0001 GMT 01 March to 2400 GMT 16 March. Phone from 0001 GMT 29 March to 2400 GMT 13 April.

OBJECTIVE: Work as many stations in as many different CPR Zones as possible. Countries do not count. Work your own Zone only once for Zone credit.

BANDS: All bands, 1.7 through 30 MHz.

EXCHANGE: RS or RST report plus your CPR Zone number.

DUPLICATE QSO'S: You may work the same station as often and for as long as you wish. When a single QSO exceeds 6 minutes a new log entry shall be made for each 6 minutes or part thereof.

LOGGING: Use GMT only. QSO's may be made with stations not in the contest if all necessary information is logged.

SCORING: 1 point for each QSO except in your own Zone. Multiplier 1 for each Zone on each band, including your own Zone. Total score is the sum of all contacts multiplied by the total Zones for all bands.

CLASSES: Single operator–single band; Single operator–all band; Multi-operator–all band; RTTY–all band; Mobile–all band; All events–all band.

AWARDS: Winners in each category will receive a suitable certificate or other award. All entries of 100 or more valid QSO's will receive a CPR Certificate.

Logs and summary sheets may be obtained from IARC, Box 6, 1211 Geneva 20, Switzerland, or from L' Rundlett, 2001 Eye NW, Washington DC 20006. Logs must be posted by 1 June 1969 to Mr. Rundlett.

Linear Systems Acquires SBE

Linear Systems, Inc., of Watsonville, California, well known in amateur radio for its' "Century" and "Commander" mobile power supplies, has recently acquired the SBE amateur transceiver line. The acquisition of SBE is in line with the company's objective of becoming a principal factor in the amateur market. An improved version of one of the foremost products in the line, the SB-34 transceiver, will be available in early 1969. Linear Systems intends to introduce other new transceivers, power supplies and accessories for the amateur market during the coming year, however the SB-34 will continue to be an important part of the line for a considerable time to come.

RAGS HAMFEST MARCH 29TH

The Radio Amateurs of Greater Syracuse annual hamfest will be Saturday, March 29th, at the Song Mountain Ski Center near Tully. 10AM 'till 9PM; flea market, contests, tech talks, snacks, plus buffet dinner and main speaker. Come and have fun!

Testing The Minilab

Since we, as amateurs, are supposed to be able to make reasonable repairs on our equipment by ourselves, it behooved us to have enough test equipment on hand to find out what has gone wrong when disaster strikes. This can lead to a whole workbench full of expensive gear if it gets out of hand.

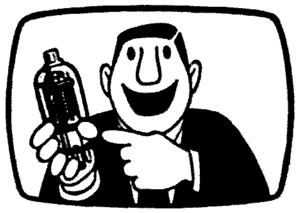
A recent ad in 73 for The Minilab seemed worthy of investigation. When our unit arrived for test we found that it was the usual VOM size, but that it had a printed circuit board and solid state circuits which made it not only a fine volt-ohmmeter, but also an rf field strength meter, an rf signal generator, an af signal generator and a substitution box for resistors and capacitors.

The af generator makes it possible to check out any audio circuit quickly, whether it be in a transistor radio, the transmitter speech equipment, a hi-fi amplifier or preamp, or a commercial sound system. The rf generator is tuned to 455 kHz and permits checking out the i-f system of most receivers. This oscillator can be retuned to 500 kHz if desired. This also is useful in providing a bfo injection for receivers which lack this function and will make even the little transistor short wave receivers capable of tuning in sideband signals or cw for you. The stability of some of these units can be something else though.

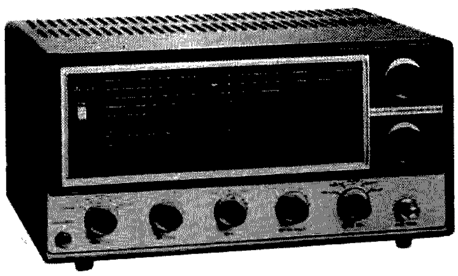
Once you think you've located a faulty part it is invaluable to be able to switch in a sample replacement to see if it makes the circuit work right. The Minilab has these substitution components built in.

Checking out a transmitter? Between the af generator and the rf field strength meter you can get a good idea of what is going on. There is a 9v battery output for testing transistor gear.

The Minilab is extremely well built. It uses a standard 9v transistor battery for powering the solid state circuits and two pencil light batteries for the ohmmeter function. The price of $25 seems quite reasonable for a package like this. Quite reasonable. Available from DGP, Box 431, Jaffrey, N.H. 03452.



NEW PRODUCTS

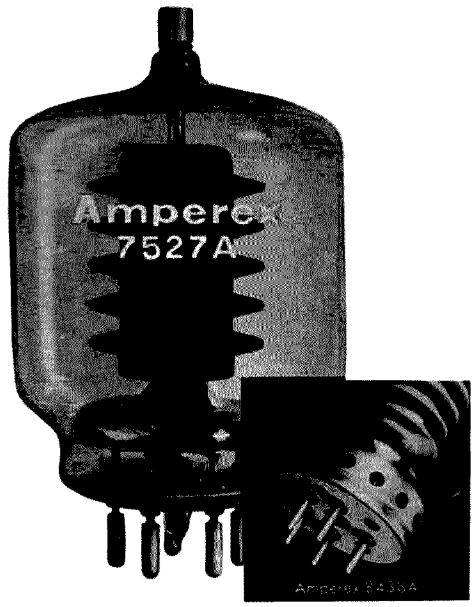


Allied Solid-State Receiver

This Allied Receiver, model A-2515, is designed for use by Short Wave listeners as Hams. The 5-Band AM/CW/SSB unit, featuring advanced solid-state circuitry, tunes all Amateur bands from 80 to 10 meters, international short wave, aircraft, marine and other short wave broadcasts and the standard AM broadcast band. Bands covered are 150-400 KHz, 500-1600 KHz, 1.6-4.8 MHz, 4.8-14.5 MHz and 10.5-30 MHz.

Of the 24 semiconductors in the circuit, two are Field Effect Transistors in the RF stage to provide exceptional sensitivity and low noise level. Four mechanical filters are used for sharp station separation; noise limiter and automatic volume control reduce noise, blasting and fading. Built-in variable BFO and Product Detector give clear reception of code and single sideband. Visual tuning is made easy with an illuminated S-meter. The illuminated slide-rule dial has calibrated band-spread for 80-10 meter Ham bands.

Other features are a push-pull audio stage with thermistor for low distortion, receiver muting connections and a headphone jack for private listening. Equipped with dual power supplies, 117VAC and 12 VDC, the receiver can be operated from house current, cars, boats, trailers and at camp sites. Price of the receiver is $99.95. A separate speaker is priced at $9.95. Allied Radio Corporation, 100 N. Western Ave., Chicago, Ill. 60680.



New 4-400A!

Amperex has stolen the lead on the industry with their new model of the popular 4-400A tube. There are two big improvements in this new tube. First is the new mesh cathode which is not only significantly stronger than the older cathodes, but eliminates noise caused by vibration and reduces hum to better than −60 dB. Second is the anode made out of graphite instead of sheet tantalum. The high thermal capacity of graphite virtually eliminates any possibility of damage to the tube due to temporary overload. Tantalum-sheet anodes are easily damaged by local overheating.

The glass base model of this tube is the 7527A and the metal shell base tube is the 8438A. Both have the Amperex sintered glass base for strength and better heat distributing characteristics. Write Amperex, Professional Tube Div., Hicksville, NY 11802 for complete data. Please mention 73.

K3QDD Receives Scholarship

Twenty-one amateur radio clubs in the Washington-Baltimore-Northern Virginia area have provided funds to the Foundation For Amateur Radio, Inc., for a $500 scholarship award. Richard Tavin, K3QDD, was awarded the John W. Gore Memorial Scholarship on the basis of his amateur radio activities and his high scholarship standing at MIT. Most laudable.

New Books

Semiconductors: From A to Z by Dahlen. Published by TAB at $4.95 paper and $7.95 cloth bound. 272 pages, over 300 illustrations. Here it is, theory and practical application of every known type of semiconductor, right on up through Integrated Circuits. Covers diodes, FET's, MOSFET's, tunnel diodes, varicaps, photo-FET's, light sensitive and emissive devices, unijunctions, field-effect diodes, SCR and zener diodes, etc. Written for the average ham rather than the engineer. TAB Books, Blue Ridge Summit, PA.

Handbook of Transistors, Semiconductors, Instruments and Microelectronics, Thomas. Published by Prentice-Hall, Englewood Cliffs NJ at $20 in cloth. This is more for the engineer, the circuit designer or the laboratory technician. It is a practical guide to semiconductor operation, formation, ratings, characteristics, circuitry and applications. If you work with semiconductors this book is important to you.

There are 62 specific symptoms of trouble in a TV set, 14 color, 44 monochrome, and 4 sound. The **TV Servicing Guidebook: Problems & Solutions**, by Art Margolis, published by TAB Books, Blue Ridge Summit, Pa., at $3.95 in paperback and $6.95 in hard cover, describes 30 separate trouble-shooting approaches which those 62 symptoms call for. Service TV sets quickly, eliminate waste motion, cut trouble-shooting time to the bone. This is a practical how-to-do-it book, lavishly illustrated. 176 pages and over 100 illustrations.

104 Ham Radio Projects for Novice & Technician by Bert Simon, W2UUN, published by TAB Books, Blue Ridge Summit, Pa., at $3.95 paperbound and $6.95 hardbound. These are, for the most part, relatively simple circuits that will not strain the junk box severely. There are projects for 80, 40, 15, 6 and 2 meters, as well as UHF projects for 220, 432 and 1296 MHz. There are antenna projects, audio circuits, CW, preamps, preselectors, converters, and plenty of accessories. If you like to build or even think you would like to build, then this book will keep you busy for a long time.

Transistor Circuit Guidebook

Bad luck? Thirteen headings and up to 21 circuits per heading hardly qualifies as bad luck. More likely it is good luck for the purchaser, since anybody purchasing this book should find interesting material in it.

The circuits are supplied as schematics with parts lists and accompanying text. Their complexity ranges from a simple "rf Booster" circuit to complete systems for radio reception, hi-fi or counting and control purposes. Many of the entries are based upon manufacturer's literature showing applications for recent solid-state products.

Very complete information is included with some of the circuits, but others will require a bit of research before construction. Many of the circuits appear instantly adaptable to new projects. Ideas may be generated by looking, for instance, at schematics for 50 and 100 watt transistor rf amplifiers, an FM tuner front end circuit which could be adapted to six or 2-meter operation, an IC IF amplifier, or a common-base dip oscillator.

The intergrated-circuits application schematics (there are several of these) include a remote-control system, a low-noise amplifier, and three counter circuits. A decimal counter uses four bistables and ten NOR gates, but some ingenuity or careful reading may be needed to choose the appropriate IC's for this one.

A total of 104 circuits are presented in this handy 224 page book. Tab' #470 Transistor Circuit Guidebook is available at your dealer's or from TAB Books, Blue Ridge Summit, Pa. 17214. Price is $6.95 hardbound or $4.95 in paperback.

Electronic Circuit Design

Modern Electronic Circuit Design, by James D. Long. 284 pages; 170 illustrations. McGraw-Hill, $12.50.

Something very interesting is happening in electronics. The business is getting very complicated, and so is the hobby, but modern writers are finding better ways to present the subject. One change appearing in recent years is the development of approaches to the subject that are intermediate in diffi-

culty between the no-math elementary approach (almost useless to anybody working at a level above that of wire-man) and the thorough-going network- and systems-analysis engineering approach.

Here is an example of this trend. The first real-circuit problem appears on page 3, and after two additional chapters of introductory material your attention is brought to one of the most basic facts of practical design: the behavior of real components. How are they different from their ideal counterparts? In many ways: parasitic properties, humidity effects, ageing, for instance. One valuable but not very obvious example is the difference between tolerance and stability of a capacitor.

Later chapters deal with equivalent circuits, transistor limitations, operating-point stabilization (a vitally important matter, if the circuit is to be reliable), and finally amplifiers and switching circuits.

Long's approach requires less math than good technicians are expected to understand, and the book contains many worked problems chosen to resemble real design problems. If you are feeling frustrated by experiences with circuits you've picked out of a book, or would like to work up something that's really your own development (and this is easier than you may believe) this book deserves your attention.

Test Instrument Projects

101 *Easy est Instrument Projects,* by R. Brown & W. Kneitel. From H. W. Sams & Co., 1968. $3.95 in paperback.

If you are interested in simple test instrument projects, here are a hundred and one suggestions complete with three handy substitution and color code tables.

Their complexity ranges from a simple battery-and-lamp continuity tester or a very basic signal tracer circuit through a more elaborate transistor checker and some power supplies to a metal locator, several test oscillators, and frequency calibrator circuits.

The projects listed in this book really are easy. All are simple, and additional data provided by the authors includes some hints and suggestions on parts substitutions.

FM Receivers

Frequency Modulation Receivers, by A. B. Cook and A. A. Liff. Prentice-Hall Inc., 1968.

This 527 page book is a thoroughgoing discussion of wide-band FM circuit technology. It is based upon an unusually small math background, not including any calculus, which will make it accessible to many radio amateurs and to service workers interested in this key part of the commercial electronics field. Wideband FM is a very effective system for conveying speech and similar signals, and after looking at this book I begin to see some of the reasons for its good reputation.

Most of these appear in the first three chapters of the book. These are, respectively, "Introduction," "Interference," and "Noise." Following this opening the writers proceed to discuss, one part at a time, the basic circuit sections common to all FM receivers (good designs are invariably superhets, but there is some variety of FM detector circuits). The last three chapters deal with tuning indicators, some miscellaneous topics, and with stereophonic broadcasting. Coverage of all topics is quite complete.

If you are interested in wideband FM for communications purposes, as a hobby, or if it plays a part in your career, this book certainly deserves your interest.

Bench-Tested Communications Projects

What is the difference between a bench-tested communications project and another project that is not bench-tested? Maybe it is in the excellent photography, or perhaps in this book's good choice of subjects that are interesting, useful and not too hard to build. That is a rather hard mix to achieve, in real life.

The book is broken into four general sections: Experimenters' Delights, a set of six assorted circuits of general interest; Communications Capers, several projects interesting to hams and to CB'ers; Better Listening six circuits useful to anybody who is listening on the ham or shortwave bands, and Workbench Wonders, three test circuits and some good suggestions on using subassembly construction when making up new gear.

All the circuits described in this book have been published previously, and its editor, Julian Sienkiewicz of Radio-TV Experi-

menter and Elementary Electronics, has personally worked with them. This complete collection of construction articles is available from the Hayden Book Co., Inc., 116 West Fourteenth St., New York, N.Y. 10011 and is very reasonably priced at $3.25. Ask for their book #0788, *Bench-Tested Communications Projects.*

Data Book

Data Book for Electronic Technicians and Engineers, by John Lenk. From Prentice-Hall, $7.25.

If you are working in electronics, or have more than a passing interest in designing and building your own circuits, you might examine a copy of this book. Its writer has tried to sort out from all the thousands of possibly interesting or useful facts, charts, tables, and equations, the ones that are basic or specially interesting. He doesn't claim to meet all requirements, but has tried to supply a generally useful collection. I would say he has succeeded.

Chapter 1 is a review of the appropriate mathematics. It is not difficult mathematics, and the pages are not cramped full of tightly packed little bits of information. Following this are sections on passive circuits, and the components used in passive circuits. One chapter goes to AC concepts, another to antenna and transmission line data. Vacuum tubes are covered well, but transistors are hardly mentioned. There is a large appendix of tables, symbols, and some math functions.

Placing equations and other data very close to diagrams representing the system described is a nice idea that could get more frequent application. There is an unusual amount of explanatory text in this book, and that is a successful variation, too from some common practice.

The book is oriented to the needs of communications, rather than of industrial or control type circuit workers.

Modern Electronic Troubleshooting

Would you like a really complete book on troubleshooting electronic circuits? A book which is written to be used? Probably most technicians and engineers who are working with electronics gear could use a look at this remarkably thorough book which manages to convey a lot of basically useful information without getting very theoretical. It starts with some ideas about checking diodes and transistors, spends a chapter on printed circuits, another on capacitors, and then goes into more general material.

This includes TV circuits, of course, and transistor radios. Two-way mobile gear is well covered, too. Certain types of problems receive special attention, and the entire text is scope-oriented simply because the oscilloscope is an indispensable tool for any serious serviceman. Since not all workers can invest large sums in the modern triggered sweep scopes, one chapter describes the installation of a transistor circuit for conversion of any inexpensive repetitive-sweep scope to a triggered-sweep instrument. There are chapters on other items of test gear, as well, adding up to 23 chapters in all. The illustrations are very good.

The price is $4.95 in paper but serious workers will probably prefer the $7.95 hardcover edition, which will stand more use. This book is a Best Buy, ask for their book #474, *Modern Electronic Troubleshooting,* from TAB Books, Blue Ridge Summit, Pa. 17214. But before you send for it, check your local distributor's shelves.

Modern TV Waveform Analysis

Should you be interested in TV servicing? Yes, and there are two good reasons. If there is any clear example of a complex technology appearing in people's homes, it is TV circuits. Those who feel TV programming is deficient in value must agree the technology that brings it into the living room is a remarkable achievement.

And another reason is that many amateurs are becoming interested in TV and TV-type transmissions. A study of the appropriate theory, even a careful and complete study, cannot develop the familiarity that comes when you try to understand what happens when the circuits do *not* work. This

is the acid test. It sorts out the fellows who read one book so many times it's engraved on the skull, from those who look around more generally and find out how the circuits work.

One good book for the serious TG worker is *Modern TV Circuit & Waveform Analysis,* by Stan Prentiss. Stan's key idea is, what do you see if you look at the circuit with a good scope? Appropriate test gear is assumed throughout, which is a necessary assumption for the serious worker and a simplifying one for the man who is seeking a better background.

Chapter 1 discusses the basic waveforms and the circuits in which these waveforms are observed. Eight following chapters discuss the operation, adjustment and servicing of the basic circuit groups in TV sets. The color TV circuits should have received stronger emphasis in the Table of Contents since a quick glance could suggest the book does not treat this subject. Actually, it comes up in several chapters and Chapter 9, Chroma Circuits, is entirely devoted to this subject.

And Chapter 10 discusses troubleshooting solid-state circuits. It starts with notes on circuit design and continues to sections on locating defective parts and general troubleshooting procedures. Finally, several charts suggest approaches to common problems, and some schematics of solid-state TV sets are also included.

Ask for TAB book $476, *Modern TV Waveform Analysis,* at your local dealers' or from Tab Books, Blue Ridge Summit, Pa. 17214.

Hayden Books Catalog

Where do all the good books come from? If you have been surprised by seeing a specially valuable book on somebody else's shelf or offered by some distributor you do not visit very often, maybe you would like to find out more about what is available for your use. It could be very important, in fact, in today's highly competitive world. If you have a catalog, then you can discover what to ask for.

The Hayden Book Co's catalog carries entries in twenty-seven different categories, and 15 of these could be interesting to an advancement minded electronics worker. Mathematics and mechanical technology, radio operation, space technology, electronics, electronics servicing, and computer technology are only a few of the headings you might look under, depending upon your interests and business needs.

Each book listed in the catalog is described in the standard library style, and this is followed by a paragraph or more discussing the subject matter you will find in the book. In smaller print, there is a list of the chapters in the book. You can usually determine if the book will be useful to you, after a careful reading of this material.

There are two indexes at the back of the catalog. One is a listing of the books by title, and the other a listing by author. For instance, a book by Pullen is probably worth investigating, if you are interested in circuits. Looking on page 89, we find Hayden lists two of his books.

Ask for the Hayden Books Catalog, available from your dealer's or from Hayden Book Co., Inc.,

HOWARD W. SAMS BOOKS FOR THE AMATEUR

Advanced & Extra-Class Amateur License Handbook
by Howard S. Pyle, W7OE. Provides all the information you need to obtain your advanced—or extra-class license. Makes preparation for these top licenses far easier for present holders of lower licenses. Includes sample questions for each exam. 192 pages.
20649, *only*..................................**$3.95**

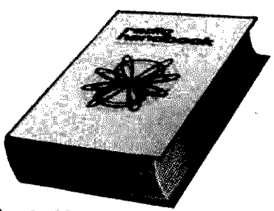
General-Class Amateur License Handbook
by Howard S. Pyle, W7OE. A complete guide, including typical FCC test questions and answers, to help you prepare for the Technician, Conditional, or General-Class radio exam. 144 pages. **20639,** *only*.......**$3.25**

Building Your Amateur Radio Novice Station
by Howard S. Pyle, W7OE. Provides complete, easy-to-follow construction details for building an inexpensive transmitter and receiver, plus several valuable accessory items, for Novice or General Class operation. 128 pages. **20050,** *only*...........................**$3.75**

International Code Training System
by International Teaching Systems, Inc. Special programmed charts and 33⅓-rpm recordings help you receive at 2-3 wpm in just a few minutes. You'll be receiving and sending up to 22 wpm with less than an hour of recorded instruction. 96 pages; 6 record sides.
20138, *only*..................................**$7.50**

Famous **Editors & Engineers** Books

17TH EDITION OF THE FAMOUS
Radio Handbook



Tells how to design, build, and operate latest types of amateur transmitters, receivers, transceivers, and amplifiers. Provides extensive, simplified theory on practically every phase of radio. All original data, up-to-date, complete, 848 pages.
EE-167, *only*...............................**$12.95**

The VHF Amateur
by Robert M. Brown, K2ZSQ/W9HBF. Completely updated handbook incorporating the finest material on vital vhf subjects from the rare back issues of the famous *VHF Magazine,* plus new data of great interest to both old and new vhf men. 160 pages.
EE-65060, *only*..............................**$4.50**

Commercial Radiotelephone License Q&A Study Guide
by Woodrow Smith & Robert Welborn. Invaluable preparation for the exams. Questions cover first four elements of the radiotelephone license exam. Answers are detailed and comprehensive. 272 pages.
EE-031, *only*.................................**$6.95**

Single Sideband: Theory and Practice
by Harry D. Hooton, W6TYH. The one-source guide to ssb, covering origin and principles, derivation of ssb signals, carrier-suppression techniques, sideband selection, and a complete analysis of ssb equipment. 388 pages. **EE-350,** *only*..........................**$6.95**

Transistor Radio Handbook
by Donald L. Stoner, W6TNS & Lester A. Earnshaw, ZL1AAX. Covers the use of transistorized communications equipment for amateur and commercial applications. Provides simplified theory, plus practical construction projects for solid-state equipment. 180 pages.
EE-044, *only*.................................**$5.00**

Amateur Radio Incentive Licensing Study Guide
by Robert M. Brown, K2ZSQ/W9HBF and Tom Kneitel, K2AES. Fully explains the new incentive licensing which affects both newcomers and old-timers. Covers all the new FCC Regulations and band allocations. Includes sample exams for Novice, Technician, Conditional, and General-Class licensing. 160 pages.
EE-050, *only*.................................**$2.75**

Amateur Radio Construction Projects
by Charles Caringella, W6NJV. Shows how to build novice transmitters, converters, all-band phone-cw transmitter, and others. Provides detailed, easy-to-follow building and operating instructions. 136 pages.
20045, *only*..................................**$3.25**

Ham Antenna Construction Projects (2nd Ed.)
by J. A. Stanley. Practical guide to custom-building your own antennas; describes all types of arrays, installation, tuning up and testing; shows you how to make the best use of antenna power. 160 pages.
20654, *only*..................................**$3.95**

101 Easy Ham Radio Projects
by Robert M. Brown & Tom Kneitel. A selection of easy-to-build, inexpensive circuits for a variety of worthwhile ham devices. Provides brief descriptions, construction hints, diagrams, and parts lists; includes substitution guide appendix. 160 pages. **20674,** *only*.........**$3.95**

Transistor Transmitters for the Amateur
by Donald L. Stoner, W6TNS. Shows how to build solid-state crystal checker/calibrator, low-power cw xmitter and eight other transistorized projects. 128 pages.
20450, *only*..................................**$3.25**

Amateur Radio Antennas (2nd Ed.)
by Harry D. Hooton, W6TYH. Provides full details on theory, design, construction, and application of antennas. Tells how to select the best antenna system for optimum performance. 176 pages. **20611,** *only*....**$3.95**

Practical Ham Radio Projects
by Charles Caringella, W6NJV. Includes circuit diagrams, parts lists, and detailed instructions for building 12 unique and useful ham shack devices at the lowest possible cost (no item exceeds $50). 128 pages.
20042, *only*..................................**$2.95**

Transistorized Amateur Radio Projects
by Charles Caringella, W6NJV. Presents a complete selection of transistorized ham radio construction projects for the beginner as well as advanced amateur. Includes several printed-circuit board projects and the negatives for etching them. 140 pages.
20570, *only*..................................**$3.50**

So You Want to Be a Ham (4th Ed.)
by Robert Hertzberg, W2DJJ. Completely revised to include information on the incentive licensing. This is the book to have to learn about amateur radio, ham equipment, operating procedures, and how to pass the FCC exam. 192 pages. **20607,** *only*..................**$4.50**

ABC's of Ham Radio (3rd Ed.)
by Howard S. Pyle, W7OE. Enlarged and updated to include all the study material required to obtain the novice-class license. Covers latest FCC regulations, including new incentive licensing provisions. 144 pages.
20638, *only*..................................**$2.95**

Amateur Radio Mobile Handbook
by Charles Caringella, W6NJV. Provides complete information for going mobile. Explains circuitry and construction of commercially built mobile amateur equipment. Shows how to build mobile converters, transmitters, transceivers, and modulators, etc. 176 pages.
20035, *only*..................................**$3.50**

Technical Aid Group

Please refer any questions of a technical nature to one of the following members of 73's Technical Aid Group. These are dedicated amateurs who really want to be of help and do so without compensation. Be sure to state your problem clearly and enclose a S.A.S.E. for a reply.

John Allen, K1FWF, high school student, 51 Pine Plain Road, Wellesley, Mass. 02181. HF and VHF antennas, VHF transmitters and converters, AM, SSB, product data, and surplus.

Bert Littlehale, WA1FXS, 47 Cranston Drive, Groton, Conn. 06340. Novice transceivers, test equipment and homebrew projects gone wrong.

Bob Groh WA2CKY, BSEE, 123 Anthony Street, Rochester, New York 14619. Specializes in VHF/UHF solid-state power amplifiers, but will be glad to make comments on any subject.

G. H. Krauss, WA2GFP, BSEE, MSEE, 70-15 175 Street, Flushing, New York 11365. Will answer any questions, dc to microwave, state-of-the-art in all areas of communications circuit design, analysis and use. Offers help in TV, AM, SSB, novice transmitter and receivers, VHF antennas and converters, receivers, semiconductors, test equipment, digital techniques and product data.

Charles Marvin W8WEM, 3112 Lastmer Road, RFD #1, Rock Creek, Ohio 44084. Will help with any general amateur problems.

Stix Borok WB2PFY, high school student, 209-25 18 Avenue, Bayside, New York 11360. Novice help.

Clyde Washburn K2SZC, 1170 Genesee Street, Building 3, Rochester, New York 14611, TV, AM, SSB, receivers, VHF converters semiconductors, test, general, product data.

Richard Tashner WB2TCC, high school student, 163-34 21 Road, Whitestone, New York 11357. General.

J. J. Marold WB2TZK, OI Division, USS Mansfield DD278, FPO San Francisco, California 96601. General.

Ira Kavaler, WA2ZIR, BSEE, 671 East 78 Street, Brooklyn, New York 11236. SSB transmitting, color TV, computer programming and systems, digital, radio and remote control, rf transmission lines, dipole design, audio amplifiers, linear and class C rf amplifiers.

Fred Moore, W3WZU, broadcast engineer, 4357 Buckfield Terrace, Trevose, Pa. 19047. Novice transmitters and receivers, HF and VHF antennas, VHF converters, receivers, AM, SSB, semiconductors, mobile test equipment, general, product data, pulse techniques, radio astronomy, bio-medical electronics.

Walter Simciak, W4HXP, BSEE, 1307 Baltimore Drive, Orlando, Florida 32810. AM, SSB, Novice transmitters and receivers, VHF converters, receivers, semiconductors, mobile, test-equipment, general.

James Venable K4YZE MS, LLB, LLM, 119 Yancey Drive, Marietta, Georgia. AM, SSB, novice gear, VHF, semiconductors, and test equipment.

J. Bradley K6HPR/4, BSEE, 3011 Fairmont Street, Falls Church, Virginia 22042 General.

Wayne Malone W4SRR BSEE, 8624 Sylvan Drive, Melbourne, Florida 32901. General.

Bruce Creighton WA5JVL, 8704 Belfast Street, New Orleans, Louisiana 70118. Novice help and general questions.

Douglas Jensen, W5OG/K4DAD, BA/BS, 706 Hwy 3 South, League City, Texas 77573. Digital techniques, digital and linear IC's and their applications.

Louis Frenzel W5TOM, BAS, 4822 Woodmont, Houston, Texas 77045. Electronic keyers, digital electronics, IC's commercial equipment and modifications, novice problems, filters and selectivity, audio.

George Daughters WB6AIG, BS, MS, 1613 Notre Dame Drive, Mountain View, California. Semiconductors, VHF converters, test equipment, general.

Glen H. Chapin, W6GBL, 3701 Trieste Drive, Carlsbad, Calif. 92008. HF and VHF antennas, novice transmitters and receivers, VHF converters, semiconductors, receivers AM, SSB, general, surplus.

Tom O'Hara W6ORG, 10253 East Nadine Temple City, California 91780. ATV, VHF converters, semiconductors, general questions.

Steve Diamond WB6UOV, college student, Post Office Box 1684, Oakland, California 94604. Repeaters and problems regarding legality of control methods. Also TV, novice transmitters and receivers, VHF antennas and converters, receivers, semiconductors, and product data.

Orris Grefsheim WA6UYD, 1427 West Park, Lodi, California 95240. TV, HF antennas, SSB, VHF antennas and converters receivers, semiconductors, and general questions.

Hugh Wells, W6WTU, BA, MA 1411 18th Street, Manhattan Beach, Calif. 90266. AM FM receivers, mobile test equipment, surplus, amateur repeaters, general.

Carl Miller WA6ZHT, 621 St. Francis Drive, Petaluma, Calif. 94952. Double sideband.

Howard Pyle W7OE, 3434—7th Avenue, S.E., Mercer Island, Washington 98040. Novice help.

PFC Grady Sexton Jr. RA11461755, WA1GTT/DL4, Hedmstedt Spt. Detachment, APO New York 09742. Help with current military gear, information from government Technical Manuals.

Sgt. Michael Hoff WA8TLX, Box 571, 6937th Comm. Gp., APO New York 09665. Help with all types of RTTY both commercial and military. Also data techniques. Covers conversion of military RTTY equipment.

Eduardo Noguera M. HK1NL, EE. RE, Post Office Box Aereo 774, Barranquilla, Columbia, South America, Antennas, transmission lines, past experience in tropical radio communications and maintenance, HF antennas, AM, transmitters and receivers, VHF antennas, test equipment and general amateur problems. Can answer questions in Spanish or English.

D. E. Hausman, VE3BUE, 54 Walter Street, Kitchener, Ontario, Canada. Would like primarily to help Canadians get their licenses. Would be able to help with Novice transmitters and receivers.

Frank M. Dick WA9JWL, 921 Isabelle Dr., Anderson, Indiana 46013. Will answer queries on RTTY, HF antennas, VHF antennas, VHF converters, semiconductors, mobile, general, and microwave.

Gary De Palma, WA2GCV/9, P.O. Box 1205, Evanston, Ill., 60204. Help with AM, Novice transmitters and receivers, VHF converters, semiconductors, test equipment, digital techniques and all general ham questions.

Arthur J. Prutzman K3DTL, 31 Maplewood, Dallas, Pennsylvania 18612. All phases of ham radio. Can assist with procurement of parts, diagrams, etc.

William G. Welsh W6DDB, 2814 Empire Ave., Burbank, Calif. 91504. Club licensing classes and Novice problems.

Ralph J. Irace, Jr., WA1GEK, 4 Fox Ridge Lane, Avon, Conn. 06001. Help with Novice transmitters and receivers and novice theory.

Iota Tau Kappa Radio Fraternity W7YG, Multnomah College, 1022 S.W. Salmon St., Portland, Oregon 97205. This group of radio amateurs will answer any technical questions in the field of electronics.

Ted Cohen W4UMF, BS, MS, PhD. 6631 Wakefield Drive, Apt. 708, Alexandria, Va. 22307. Amateur TV, both conventional and slow scan.

Roger Taylor K9ALD, BSEE, 2811 West Williams, Champaign, Illinois 61820. Antennas, transistors, general.

Michael Burns Jr. K9KOI, 700 East Virginia Avenue, Peoria, Illinois 61603. AM, SSB, receivers, transmitters, digital techniques, novice help, general.

Jim Jindrick WA9QYC, 801 Florence Avenue, Racine, Wisconsin 53402. Novice transmitters and receivers, general.

John Perhay WAØDGW/WAØRVE, RR #4 Owatonna, Minnesota 55060. AM, SSB, novice transmitters and receivers, HF receivers, VHF converters, semiconductors, mobile, product data, general. Has access to full specifications on almost all standard components presently catalogued by American manufacturers.

Ronald King K8OEY, Box 227, APO New York, New York 09240. AM, SSB, novice transmitters and receivers, HF receivers, RTTY, TV, test equipment, general.

Charlie Marnin W8WEM, 3112 Latimer Road, RFD 1, Rock Creek, Ohio 44084. General technical questions.

Michael Winter DJ4GA/W8, MSEE, 718 Plum Street, Miamisburg, Ohio 45342. HF antennas, AM, SSB, novice gear, semiconductors.

David D. Felt, WAØEYE, television engineer, 4406 Center Street, Omaha, Nebraska 68105. Integrated circuits, transistors. SCR's, audio and rf amplifiers, test equipment, television, AM, SSB, digital techniques, product data, surplus, general.

Tom Goez KØGFM, Hq Co USAMAC, Avionics Division, APO New York, New York 09028. HF antennas, mobile, airborne communications equipment, particularly Collins and Bendix gear, AM, FM, or SSB—HF, VHF, UHF, general.

Robert Scott, 3147 East Road, Grand Junction, Colorado 81501. Basic electronics, measurements. ■

MOVING?

Every day we get a handful of wrappers back from the post office with either a change of address on them or a note that the subscriber has moved and left no address. The magazines are thrown out and just the wrapper returned. Please don't expect us to send you another copy if you forget to let us know about your new address. And remember that in this day of the extra rapid computer it takes six weeks to make an address change instead of the few days it used to when we worked slowly and by hand.

Surplus Conversions

Hardly a week goes by without receiving many requests from readers asking where to find information regarding a particular piece of surplus gear they have picked up without a manual or any conversion information.

In addition to the following literature, *73's Index to Surplus* should give all the information as to where to find conversion for almost any surplus equipment. This handy reference is available from 73, Peterborough, N.H. 03458 for the modest sum of $1.50.

Editors and Engineers

Editors and Engineers, P.O. Box 68003, New Augusta, Indiana, have published three *Surplus Radio Conversion Manuals* by Evenson and Beach and the *Surplus Handbook, Vol. I* by W6NJV and W6NJE. Each costs $3. Here are the pieces of equipment covered in each manual:

Surplus Radio Conversion Manual, Vol. I. BC-221, BC-342, BC-312, BC-348, BC-412, BC-645, BC-646, SCR-274 (BC-453A and BC-457A series), SCR-522, TBY, PE-103A, BC-1068A/1161A.

Surplus Radio Conversion Manual, Vol. II. BC-454, AN/APS-13, BC-457, ARC-5, GO-9/TBW, BC-946B, BC-375, LM, TA-12B, AN/ART-13, AVT-112A, AM-26/AIC, ARB.

Surplus Radio Conversion Manual, Vol. III APN-1, APN-4, ARC-4, ARC-5, ART-13, BC-191, BC-312, BC-342, BC-348, BC-375, BC-442, BC-453, BC-455, BC-456-9, BC-603, BC-624, BC-696, BC-1066, BC-1253, CBY-5200, COL-43065, CRC-7, DM-34, DY-2, DY-8, FT-241A, MD-7/ARC-5, R-9/APN-4, R-28/ARC-5, RM-52-53, RT-19/ARC-4, RT-159, SCR-274N, SCR-508, SCR-522, SCR-528, SCR-538, T-15 to T-23/ARC-5, URC-4, WE701A.

Surplus Handbook, Vol. I. This book, subtitled, *Receivers and Transceivers*, is composed of schematics and pictures of the following gear. It doesn't give conversions. APN-1, APS-13, ARB, ARC-4, LF and VHF ARC-5, ARN-5, ARR-2, ASB-7, BC-222, BC-312, BC-314, BC-342, BC-344, BC-348, BC-603, BC-611, BC-624 (SCR-522), BC-652, BC-654, BC-659, BC-669, BC-683, BC-728, BC-745, BC-764, BC-779, BC-794, BC-923, BC-1000, BC-1004, BC-1066, BC-1206, BC-1306, BC-1335, BC-AR-231, CRC-7, DAK-3, GF-11, Mark II, MN-26, RAK-5, RAX, RAL-5, Super Pro, TBY, TCS, VT tube cross index.

CQ Handbook

CQ has two handbooks on surplus out. They can be ordered from CQ, 14 Vanderventer Avenue, Port Washington, N.Y. The first book, the *Surplus Schematics Handbook*, by Ken Grayson W2HDM, costs $2.50, and contains schematics and short comments about this gear: APA-38, APN-1, APR-1, APR-2, APS-13, ARB, ARC-1, ARC-3, ARC-4, ARC-5, ARC-5 VHF, ARJ-ARK-ATJ, ARN-7, ARR-2, ART-13, ASB, AS-81-GR, ATK, BC-AR-231, BC-189, BC-191, BC-221, BC-312, BC-314, BC-342, BC-344, BC-348, BC-375, BC-438, BC-474A, BC-603, BC-610, BC-611, BC-620, BC-640, BC-645, BC-652, BC-653, BC-659, BC-683, BC-684, BC-728, BC-733, BC-745, BC-779, BC-794, BC-906, BC-969, BC-1000, BC-1004, BC-1023, BC-1206, BC-1335, BN, BP, C3, CRC-7, CRO-208, CRT-3, DAE, F3, GF-11, GO-9, GRR-5, 1-122, 1-177, 1-208, JT-350A, LM, Mark II, MD-7, MN-26, PRC-6, PRS-3, R-174, RAK, RAL, RAO-7, RAS, RAX, RBH, RBL, RBM, RBS, RC-56, RC-57, RDC, RDR, RDZ, RU-16, SCR-274, SCR-284, SCR-288, SCR-300, SCR-506, SCR-522, SCR-578, SCR-585, SCR-593, SCR-608, SCR-610, SCR-624, SCR-628, SPR-1, SPR-2, TBS, TBW, TBX, TBY, TCK, TCS, TG-34, TS-34/AP, TS-251/UP, VRC, VVX-1.

The other CQ book, the *Surplus Conversion Handbook* by Tom Kneitel K3FLL, ($3) contains conversion on these pieces of gear: ARC-1, ARC-3, ARC-4, ARC-5, ARC-36, ARC-49, ART-13, ATA, ATC-1, BC-191F, BC-224, BC-312, BC-314, BC-343, BC-344, BC-348, BC-375E, BC-453, BC-454, BC-455, BC-457A, BC-458A, BC-459A, BC-603, BC-604, BC-620, BC-624A, BC-625A, BC-659, BC-669, BC-683, BC-684, BC-696A, BC-779, BC-794, BC-946, BC-1004, BC-1068A, CBY-52232, PE-73, PE-103, R-129/U, RAX-1, SCR-177, SCR-188, SCR-193, SCR-274N, SCR-399, SCR-499, SCR-508, SCR-509, SCR-510, SCR-522, SCR-528, SCR-542, SCR-608, SCR-609, SCR-628.

Getting Your Extra Class License

Part II — Amplifiers

Almost every stage of any radio equipment contains an amplifier circuit of some sort. Understandably, the Extra Class examination includes a number of questions designed to test your knowledge of amplifier theory and its application—and this month we're going to concentrate on them.

Specifically, the questions from the FCC study list which we're going to examine in detail this time are:

6. Why is there a practical limit to the number of stages that can be cascaded to amplify a signal?

42. List Several advantages and disadvantages each for Class A, Class B, and Class C amplifier operation.

66. How are grounded-grid amplifiers used in electronic circuits? List some advantages and disadvantages of their use.

73. What improper operating conditions are indicated by the upward or downward fluctuation of a Class A amplifier's plate current when a signal voltage is applied to the grid? How can this be corrected?

74. What improper operating conditions are indicated by grid current flow in a Class A amplifier?

As usual, rather than approaching these official study questions directly, we'll paraphrase them into several other questions of broader scope, in order to better cover the subject.

The most basic of all questions that can be asked about amplifiers is "How Does An Amplifier Amplify?"—so let's ask it as a starting point. From there, we'll try to learn "Where Can An Amplifier Be Grounded?", which should take care of all the various grounding methods for signal inputs and outputs. Our third question will be "What Limits An Amplifier's Usefulness?", and we'll follow this up with a natural sequel, "How Can The Limits Be Stretched?"

By the time we find the answers to these four questions, we may not be amplifier experts but we should certainly be able to handle any questions on amplifiers which may be on the Extra Class exam, as well as many which probably won't be there. Ready? Let's get started.

How Does An Amplifier Amplify? Before we can begin to find out how an amplifier amplifies, we must decide "What is amplification?" The answer may turn out to be a bit surprising.

To "amplify" is to make larger or stronger —but even though a transformer may make an ac voltage larger than it was originally, a transformer is not an amplifier.

As it happens, in electronics to "amplify" always means "to add power". While the ordinary transformer may step up either voltage or current, it cannot add power to the signal. Even a perfect transformer can only put out the same amount of power that is fed into it. If the voltage is doubled, the current must be cut in half to meet this power requirement. Similarly, if the current is doubled, it can only be done by cutting the voltage in half. And no transformer is perfect. The best transformers still have at least some losses. This means that in any practical transformer, the power output is always *less* than that put in, never greater. This is why a transformer is not considered to be an amplifier.

Any amplifier, though, does add power to the signal. The gain may appear as a voltage gain—output voltage greater than input voltage—or as a current gain, or as both at the same time, but the output power always is greater than the input power in the amplifying device itself.

Some amplifier circuits are arranged in such a manner that the power gain is somewhat hidden. In some cases this is deliberate,

to accomplish the purpose for which the circuit is designed, and in others it's merely incidental. In all of them, though, the actual amplifying portion of the circuit must involve a power gain.

One of the most common amplifier circuits in which the power gain is "hidden" is that type of circuit generally known as a "voltage" amplifier. Since audio amplifiers are usually divided into two classes called "voltage" and "power" amplifiers, respectively, there's a strong implication that there's no power amplification in the voltage amplifier.

While it's true that most voltage amplifiers take *almost* no power from their input sources, they *do* take at least a little. The input power may be as small as a thousandth of a microwatt, but it's greater than zero. The output power, similarly, is there; if the circuit produces a 40-volt peak-to-peak output signal with a ½-milliamp plate current swing, this amounts to about 700 microwatts RMS power. It's not much—and this is why the circuits are called "voltage" amplifiers—but it's there.

And if our example amplifier takes a 1/1000 microwatt input signal up to a 700-microwatt output level, it must have a power gain of 700,000 times. This would be a fantastic figure; the power gain of most voltage amplifiers lies between 100 and 1000 times.

The so-called "voltage" amplifier, then, is just as much an amplifier of power as is the "power" amplifier, but its absolute power output is much much smaller. The power output of a voltage amplifier is useful only insofar as it produces the desired gain in voltage.

Now let's see how an amplifier goes about its business of adding power to a signal.

A moment's thought will reveal that we've already listed several necessities for amplification to occur: we must have an input signal, and a source of power which can be added. Also, we must have some means of getting the amplified output signal out of the circuit.

That's almost the complete list; only one more item is needed. That's a device which can "transfuse" power from the power source into the signal.

The devices we have to do this job don't do it in just that manner. Instead, they use the power of the input signal to *control* the flow of power from the source through the output circuit. It works out to be the same, however.

Two such devices, basically, are all we have with which to amplify ac signals. They are the vacuum tube and the transistor. Both act as electrically-controlled variable resistors, controlling the flow of current through themselves and thus through the output circuit.

The tube's plate current is controlled by the *voltage* on the grid, while the current in the collector circuit of the transistor is controlled by the *current* injected into (or withdrawn from) the base. In either case, the result of applying an input signal is to cause a variation of current flow in the output circuit. This current flow may be used directly, if current amplification is desired, or it may be converted to a voltage variation by a suitable load impedance.

The amount of control over output-circuit current flow which any particular tube or transistor's input signal can have is determined mainly by the geometry of the innards of the tube or transistor. This is the problem solved by the designer of that particular type of tube or transistor. Within certain physical limits, the designer can produce just about any combination of control effects you might want. For some purposes one combination is best, while for other jobs a completely different set of effects is necessary. That's one of the reasons why there are so many different types of tubes and transistors on the market.

When the designer has done his job, and the device is built to accomplish the desired control effects, the results are generally displayed in the form of "characteristic curves" which plot output signal against input signal. Many types of such curves are available; for our purposes we'll concentrate on the grid-voltage/plate-current family such as that shown in **Fig. 1.** This type of curve plots plate current against grid voltage; while **Fig. 1** shows only a single curve, any actual set of curves will have many, because a single tube type has a different curve for each different value of plate voltage which you might apply to it. Transistors have similar curves, not shown here.

Fig. 1 also shows how the electrically-controlled variable resistor called a "tube" is l'mited by some physical facts. At I in the figure is shown an "ideal" E_g-I_p plot for a perfect resistor. The output current depends

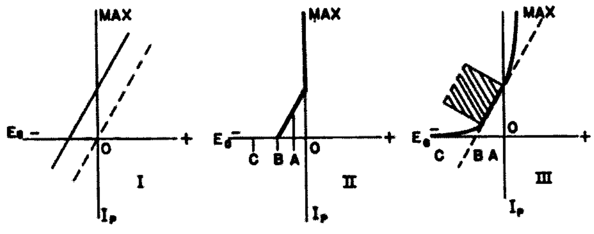

Fig. 1—Characteristics of vacuum tubes are often shown by curves which plot plate current (vertical scale) against grid voltage (horizontal). A completely linear device would produce a plot such as that at I—and the dotted line in this plot is actually the characteristic of a resistor; as voltage goes up, so does current, in a linear manner. Tubes, however, cannot operate with "less than zero" plate current, and when the grid goes positive it acts more like another plate than it does a grid, so the plot shown at II is the best that could be expected from a perfect tube. Actual tubes are less than perfect; their characteristic is curved rather than straight, and looks more like the plot at III. The shaded area in III identifies that part of the curve which is straight enough to act as if it were a straight line—normally called "the linear region" of the tube's characteristic.

only upon the input voltage, and there's no limit on the input voltage in either direction.

However, in a tube, when you've cut the plate current all the way to zero you cannot cut it down any more because there just isn't any more left to cut. This imposes a lower limit on the variable-resistance action. And when you drive the grid voltage positive, the grid then begins to act more like a second plate than it does like a grid, so you lose control at the other end as well. Part II of **Fig. 1** shows this idealized E_g-I_p plot for an actual vacuum tube.

Finally, since the actual control effects are determined by the geometry of the tube's insides, there are no sharp breaks or corners in the effects. Rather, they blend smoothly from one type of action into another. And in fact, the actual performance curve is *never* a straight line as long as current is flowing. It always curves at least slightly. This is shown as part III of **Fig. 1**.

To get perfect amplification, the curve would have to be straight as in the slanted portion of part II. Fortunately, most tubes have a fairly wide region in which the curve is almost straight—so much so that we can ignore the slight curvature—and this is indicated by the shaded region in Part III. For "distortion-free" amplification, we must be certain that we restrict all operation to this part of the curve.

As it happens, not all amplification must be "distortion-free". When we're generating *rf* for use as either an AM carrier or for CW, for example, the only things we're interested in are frequency and power level. If the level should happen to vary at the input to an amplifier, we not only are uninterested in preserving the variation unchanged at the output, but actually want the variation to be washed off by the amplifier so that the output level is steady.

In other cases, we want to preserve the variations in level of the input signal, but we may want more power output than we can get by restricting amplifier operation to the linear region of the tube's curve. If we have some means for taking out the distortion which results from overdriving, we can get the additional power.

These varying requirements which amplifiers are called upon to meet result in the existence of several different "classes" of amplifier operation. They're known as Class A, Class B, and Class C, and in addition to these three classes there's a fourth called "Class AB" which covers the entire range of operating conditions between Class A and Class B.

The definitions of the various classes have become somewhat confused through the years. The "official" definitions set up many years ago by the Institute of Radio Engineers (now a part of the IEEE) are as follows:

"A Class A amplifier is an amplifier in which the grid bias and alternating grid voltages are such that plate current in a specific tube flows at all times.

"A Class AB amplifier is an amplifier in which the grid bias and alternating grid voltages are such that plate current in a specific tube flows for appreciably more than half but less than the entire electrical cycle.

"A Class B amplifier is an amplifier in which the grid bias is approximately equal to the cutoff value so that the plate current is approximately zero when no exciting grid voltage is applied and so that plate current in a specific tube flows for approximately one half of each cycle when an alternating grid voltage is applied.

"A Class C amplifier is an amplifier in which the grid bias is appreciably greater than the cutoff value so that the plate current

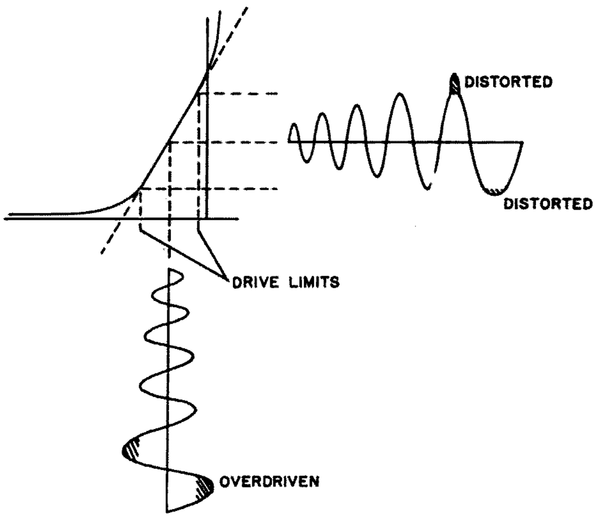

Fig. 2—A Class A amplifier is operated with a grid bias which makes the tube operate at the center of its linear region in the absence of signal. The signal voltage then varies the operating point, and thus controls the plate current. If the input signal exceeds the limits of the linear region, distortion results. The distortion is exaggerated in this illustration.

in each tube is zero when no alternating grid voltage is applied and so that plate current in a specific tube flows for appreciably less than one-half of each cycle when an alternating grid voltage is supplied."

Other definitions which have been offered specify a Class A amplifier as one in which the output is a faithful reproduction of the input signal. This is not, however, a requirement for true Class A operation even though most Class A amplifiers do have this characteristic.

Fig. 2 shows the action of a typical Class A amplifier, by plotting the variation of output current against the variation of input signal. Notice that the tube's characteristic curve furnishes the reference for making such a plot. For this reason, the E_g-I_p curve is often called the "transfer characteristic" of the tube. At any instant, the plate current is determined by the grid voltage. By plotting the variations in grid voltage (vertical waveform beneath the curve) and keeping the time scales constant, the variations in plate current may easily be determined (horizontal waveform to right of curve).

The zero-signal line which meets the tube's transfer characteristic curve in the center of its linear region marks the level of resting grid bias, and also the no-signal plate current which results from this value of bias.

The limits beyond which the input signal cannot be permitted to drive the amplifier are then determined by the points at which the tube's transfer characteristic begins to curve away from the straight line (dotted). If the signal pushes grid voltage past either of these limits as shown in the shaded regions of **Fig. 2**, the output signal will no longer be a faithful reproduction of the input signal—and distortion is the result.

The major advantage of the Class A amplifier is its freedom from distortion when properly operated. Additional characteristics which are sometimes considered advantages, and sometimes are disadvantages (depending upon the particular application) include its constant plate current. While the output signal is obtained only because the plate current varies, these variations occur as an audio rate; so far as dc instruments are concerned, the plate current remains constant with any level of input signal which may be applied. The variations cancel each other out.

The only way in which the indicated plate current can vary is for the dc bias point to change with application of signal. This occurs most frequently because of excessive input signal level. While excessive positive-going input signals may cause grid current to flow, it is not necessary to drive into the grid-current region to cause plate current to shift. Any change of plate current, either up or down, when signal is applied indicates excessive input-signal levels. The cure is simple—reduce the level of the input signal.

In many applications this constant plate current is an advantage, since it makes the amplifier present a constant load to the power supply circuits.

In other uses, the same quality is a disadvantage; for example, in a mobile or portable unit operating from batteries, it's wasteful to burn up power when no signal is being produced.

The major disadvantage of the Class A amplifier, however, is the low overall efficiency of the circuit. Most of the power supplied to a Class A amplifier is used to keep the tube at the chosen operating point. Even with a "perfect" transfer characteristic such as that in part II of **Fig. 1**, you would only be able to get output power over the region between cutoff and grid current. With practical amplifiers, the linear region is much smaller; thus the power output and

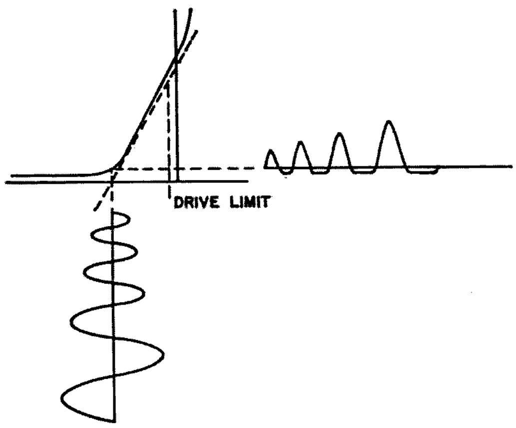

Fig. 3—Grid bias of a Class B amplifier is adjusted so that the tube has essentially zero plate current in the absence of signal. Positive-going half-cycles of the input signal then drive the operating point over to the linear region. Negative-going half-cycles are lost. The output signal is nighly distorted; in an RF Class B amplifier, only the modulation envelope is important and distortion of the individual RF cycles has no effect. In audio Class B circuits, push-pull arrangements are necessary to supply the missing half-cycles. Since the tube is passing no current half the time, it can handle considerably more power on the average.

total efficiency of the Class A amplifier are both kept relatively small. Plate current can swing only from zero up to the positive limit, and this swing must supply both halves of the output-signal cycle.

If, however, we change the grid bias to approximately the cutoff value for our tube, we convert our Class A amplifier into a Class B amplifier. This amplifier's operation is plotted in **Fig. 3.** Notice particularly that the *only* change we made was to move the grid bias level. The circuit itself remained unchanged. The differences between the various classes of amplifiers is entirely a matter of adjustment, not of circuitry!

With the resting grid bias at approximately the cutoff value, almost no plate current flows in the absence of input signal. When a signal is applied to the grid, the negative-going half-cycles of the signal merely bias the grid even farther into cutoff and stop all plate current, but the positive-going half-cycles move the tube's operating point up into the linear region.

As a result, the positive-going half-cycles are reproduced faithfully in the output signal, at the cost of the negative-going halves of the signal.

The output signal of a single-tube Class B amplifier is highly distorted, and such an amplifier cannot be used in this simplified version if faithful reproduction is what we're after.

However, if we simply add one more tube and feed it the same input signal—except in reversed phase—then the "positive" halves from one tube will fill in the gaps caused by the missing "negative" halves of the other, and our total amplifier will be relatively free of distortion. This is the push-pull circuit in its most natural form, and any Class B amplifier used for audio must be in a push-pull circuit to keep distortion within acceptable limits.

Additionally, tubes designed especially for Class B operation are preferable for such applications. These tubes are built to have the sharpest possible "knee" between the cutoff and linear regions ,to minimize "cross-over distortion" which occurs at the "cross-over points" between one tube and the other.

The Class B amplifier provides greater power from the same tubes than does Class A operation. Not only is twice the current swing available (Class A must get the whole cycle into the current swing between zero and maximum, while Class B need get only a half-cycle into the same current swing), but the fact that each tube is cut off and thus "resting" for half of each cycle permits us to pour more power into the circuit without damaging the tubes.

Where the overall efficiency of a Class A power amplifier lies between 25 and 30 percent in practice, with a theoretical limit of 50 percent, that of the Class B amplifier runs between 30 and 50 percent in practice and the theoretical limit is 86 percent.

This increased power is the primary advantage of Class B operation. A secondary advantage is the fact that most of the current drawn from the power supply goes into the output signal; no power is wasted keeping the tube at a fixed operating point. The variation in current with signal may sometimes be a disadvantage, though, since such an amplifier presents a varying load to its power supply, and the power source must then be capable of accomodating a wide range of load conditions.

The major disadvantage of Class B operation is the increased distortion and requirement for push-pull circuits. The push-pull requirement is not present in a Class B amplifier used for "linear" amplification of *rf*, since there we don't care about distor-

tion in the individual *rf* cycles. What we want to keep "linear" in such an amplifier is the modulation envelope of the signal, and the Class B amplifier preserves this nicely in its single-tube version.

A secondary disadvantage is the fact that a Class B amplifier requires more careful adjustment to obtain the proper operating point. Grid bias, especially, is extremely critical in this one.

The Class AB circuit was developed primarily to overcome these disadvantages of true Class B operation, and does so to a great degree—although the disadvantages do remain as the major ones of Class AB operation as well.

In a Class AB amplifier, bias is not so great as in Class B. Thus some plate current flows even with no signal. When signal is applied, the positive-going portions permit additional plate current flow just as in Class B operation, while the negative-going portions tend to cut plate current off completely. However in a push-pull Class AB amplifier (and almost ass AB amplifiers *are* operated in push-pull arrangements) the other tube supplies the missing half cycle.

The cross-over from one tube's operation to the other occurs at the resting value of plate current, though, which means that both tubes are in operation for very small signals and the first-one-then-the-other action applies only to the larger input signals. Because the transition from cut-off to the linear region of the tubes' transfer characteristic is gradual rather than abrupt, moving the crossover point to a higher plate-current value tends to reduce crossover distortion.

In the Class A amplifier, the main objective was to accomplish "linear" amplification without distortion. In both the Class B and the AB amplifiers, the idea was still to amplify without distortion, but circuit tricks were necessary in order to get rid of the distortion introduced by AB or B operation.

The Class C amplifier, on the other hand, is intended to distort its input signal. That is, its purpose is to put out the largest practical amount of power while washing off all variations of signal level which may be present in its input.

To do this, the tube's operating point must be changed rather radically. Instead of operating at the center of the linear region, as in Class A; at cutoff, as in Class B; or somewhere between, as in Class AB, the Class C amplifier is adjusted to an operating point far below the cutoff region. Thus no plate current can flow in the absence of an input signal. This is true of a Class B amplifier also, but with Class C because of the much greater bias the plate current remains zero even *after* input signal is applied, until the input signal goes sufficiently positive to overcome the added bias.

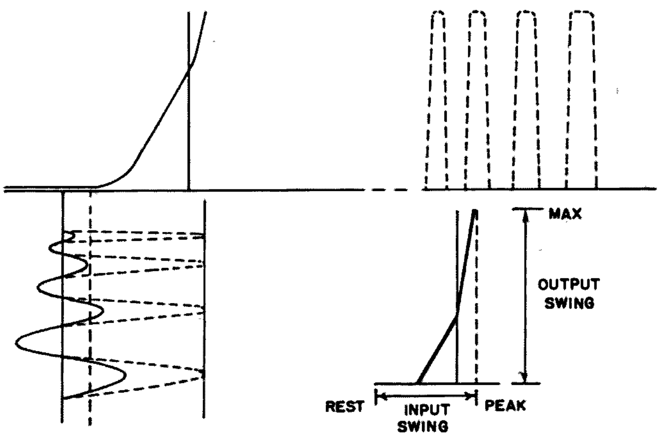

Fig. 4—Class C amplifier is biassed far beyond cutoff, so that tube acts more like a switch than a resistance. Only extreme positive peaks of input signal permit current to flow through tube. Signal is totally distorted; this type of amplifier is used only when amplitude distortion is unimportant. Since tube is resting most of the time, this class of circuit permits maximum power from the tube. Efficiency up to 80 percent is not uncommon. Idealized curve, inset, shows how circuit's characteristic resembles switch more than normal amplifier.

Fig. 4 shows the operation. With a normal-level input signal (solid waveforms) only the extreme tips of the positive half-cycles overcome the additional bias, and the output signal consists only of brief current pulses.

But Class C amplifiers are used primarily for *power* amplification of *rf* signals, rather than as voltage amplifiers, and in this application are driven with signals so large that they would be excessively strong signals to the other classes of amplifiers. Such an input signal and its corresponding output are shown in dotted lines in **Fig. 4.**

Actually, in a Class C amplifier, the tube is being used more like an electronic *switch* than as a variable resistor. There's really no difference, if you keep in mind that an ordinary switch is actually a resistor with two values (one very high, in the billion-ohm region, and the other very low, meas-

ured in hundredths of an ohm). When you operate the switch, you choose one of the two values.

In the Class C amplifier, the very high value of grid bias establishes the extra-high-resistance or "off" condition of the switch-resistor represented by the tube. The "over-drive" level of the input signal establishes the low-resistance or "on" condition. And the transition between one condition and the other, which carries operation all the way through the linear region of the tube, is made very rapid by the sharp rise and fall of the signal waveform.

The inset illustration in **Fig. 4** brings out this characteristic of the Class C amplifier. For Class C use, the linear region of the tube's transfer characteristic is only a nuisance. Tubes designed primarily for Class C operation, as a consequence, may not behave very well if you attempt to use them as linear amplifiers.

The advantage of Class C operation is its efficiency. Theoretically, you can get as close to 100% efficiency as you like in a Class C circuit. In practice, 75 percent efficiency can be reasonably expected, and with a little care it's possible to stretch this to 85 percent or so (the remaining 15 percent of output power can be gotten, all right, but it's in the form of high-order harmonics of the input signal, and any attempt to *use* it will get you in trouble for excessive harmonic radiation!).

Because the tube is being used as a switch, virtually all the dc power taken from the power supply goes into the output signal. The only part lost in the tube is the voltage drop from plate to cathode, which usually is only 20 to 50 volts at most; the rest of the losses occur in the associated tuning circuit, and in the process of converting those switched current pulses back into a reasonably harmonic-free signal waveform.

An additional advantage is that the power output of a Class C amplifier is not affected by the input-signal level (so long as the input drive is enough to reach the maximum-output level), but *can* be controlled easily by controlling the applied plate voltage. This means that modulation can be applied to a Class C amplifier with ease.

The steady output level without regard to input level, after a certain input threshold is reached, provides still another advantage. A Class C amplifier can be used whenever a signal *limiter* is needed, so long as there's no need to retain any of the amplitude variations. FM receivers sometimes use one or two stages of Class C amplifiers in their *if* strips for just this purpose.

Disadvantages of Class C amplifiers vary depending upon the application. The most obvious is the extreme amplitude distortion of the input signal, which makes them impractical for use with signals which must be amplified linearly (such as SSB or low-level-modulated AM). The high harmonic content of the output, if too great efficiency is sought, is another potential disadvantage; it may be overcome by keeping grid bias as small as possible while retaining the desired operating conditions, and keeping "drive" (input signal level) as low as possible consistent with desired operation.

Where Can An Amplifier Be Grounded? In addition to the various "classes" of amplifier operation which we have just examined, and which depend upon adjustment rather than upon circuit changes, there are many different amplifier circuits.

Many of the differences in these various amplifier circuits have to do with the grounding of the amplifier. For instance, the "normal" amplifier arrangement—that is, the one most commonly encountered—operates with its cathode grounded.

The cathode is not always actually directly grounded (although it frequently *is*, especially in *rf* amplifiers), but it is used as the return point for both the input and output circuits.

But we also have grounded-grid amplifiers, and, strange as it may sound, a grounded-plate circuit. The grounded-plate circuit is more often called the "cathode follower".

These different types of grounding for the input and output signals lead to vastly different sets of operating characteristics for otherwise identical amplifiers. The answer to our question can be fully expressed only if we can learn *how* the different groundings make such vast changes in amplifier action.

Let's start by forgetting all about amplifiers, tubes, and the like for a moment and considering a simple "black box". This is one of the favorite phrases of modern engineers, and with good reason. Any circuit whatever can be considered as an opaque black box; all we need know about it is

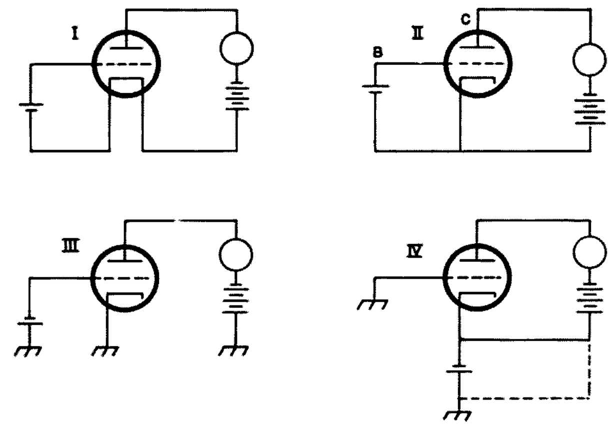

Fig. 5—Any amplifier circuit reduces to the basic arrangement shown at I; the separate input and output leads to the cathode are to emphasize the difference between input and output circuit. The version shown at II is electrically the same. It may be grounded at any of points A, B, or C, or even at other points not directly associated with a tube element. Most often, the cathode is grounded as shown at III; this permits both the input and output circuits to work "against ground". If the grid is grounded but the plate supply left ungrounded as shown by solid lines at IV, the circuit is not changed. Breaking the plate-supply return at X and connecting it as shown by the dotted lines does *change circuit action; text explains how and why.*

what its input and output terminals make it act like. What is actually inside couldn't concern us less, because in any practical application of theory, it's the results that count rather than how they got there!

The classical "black box" studied by engineers usually has four terminals; two of them are input, and the other two are for output. Any needed power supply is considered to be inside the box.

Any amplifier, you can see, can be thought of as such a box. We put a signal in at the input terminals, and we get out the amplified signal at the output.

Similarly, just a vacuum tube is also a "black box". We don't have to completely understand the electron physics involved, or the three-dimensional geometry which dictates the transfer characteristic, in order to make good use of the tube. All we need do is supply it the proper voltages, an input signal, and take off the output signal.

Right now let's ignore all the extra grids found in most modern tubes and think only of the classic triode with cathode, grid, and plate (the multi-grid tubes operate on the same general principles as the triode, anyway).

The electrons boil off the heated cathode and are drawn to the plate by the positive plate voltage. On the way, they must pass the grid; the voltage between grid and cathode controls the number of electrons which negotiate the path from cathode to plate.

Note that since we have only three elements in this tube, we cannot have four separate terminals on the black box model of it. Two of the four terminals *must* connect to the same element.

And the mechanics of tube action dictate that the cathode must be the doubled-up element, common to both input and output circuits. The controlling voltage is that between grid and cathode. The current controlled is that between cathode and plate. The control terminals, or input, then must be the grid and the cathode, while the controlled terminals, or output, must be the cathode and the plate.

So the tube is a three-terminal black box, rather than four. **Fig. 5** shows this schematically; part I shows the input and output circuits separately, using two leads to the cathode, while part II uses a common cathode lead.

Now so far as the tube is concerned—but only under some rather strict restrictions—it makes no difference at all which of these three terminals is connected to an external ground. In fact, all three could be kept ungrounded, and the tube would still do the same job.

But this is true only if both the input signal and the output signal are isolated from ground, both on the supply and the return sides of the circuit, and the power supplies also.

In any practical amplifier circuit, "ground" means much more than just a connection to chassis. "Ground" is the reference point for all circuits, and is used to shield from each other circuits which must be kept isolated.

And when "ground" is used in this way, then it does make a major difference whether the tube is grounded at point A or at point B.

When the cathode (point A) is grounded, as in part III of **Fig. 5**, then the input signal is applied between grid and cathode and the output signal is taken between plate and cathode. This corresponds to "normal"

action within the tube and so is the "normal" connection for an amplifier.

When we ground the grid instead (point B), as in part IV of the illustration, the first effect is that the phase of the input signal is effectively reversed because it is grounded on the opposite side of the circuit from "normal" connection.

If the isolated-output situation exists the circuit would be as shown by solid lines in part IV, and except for the phase reversal the circuit would behave exactly the same as that of part III. But the normal connection of output components and power supplies is as shown by dotted lines—and this puts the input and output circuits in series with each other.

This, in turn, means that all of the *output* amplified current must flow through the input circuit. Polarities are such that the input and output signals are in the same phase, so our grounded-grid circuit has 100 percent positive feedback. It's kept from oscillating by the fact that the feedback is *current* feedback while the tube amplified *voltage*. Still, the feedback results in much lower input impedance, and much higher output impedance, than we would find in a grounded-cathode circuit using the same tube in the same application.

The grid being connected directly to ground makes it an effective shield between plate and cathode, and this in turn permits operation of the tube at frequencies which otherwise would be too high to be practical for a given type of construction. It was this characteristic for which the grounded-grid amplifier was first developed, and is still one of the major uses of this type of circuit.

Since the input and output circuits are in series when the grid is grounded, any excess power in the input signal (above that necessary to drive the amplifier) passes on through to the output. This characteristic is taken advantage of in the SSB linear-amplifier circuits which employ grounded-grid stages; the low input impedance makes a good match to low-power transmitters used as exciters, and the power feed-through makes it unnecessary to swamp out excess input signal.

If the plate, rather than the grid, is grounded, then the input and output signals are effectively in parallel rather than in series. This prevents the output voltage from ever rising above the input voltage level, but allows current amplification.

In this case, the feedback is of voltage rather than current, but is negative rather than positive. The 100-percent feedback reduces distortion, and produces very low output impedance and high input impedance.

Cathode followers find wide use in preamplifiers and test instruments, to present a very high input impedance and reduce loading upon the circuits under test. They are also employed in conjunction with other amplifier circuits for special uses which we'll examine a little later.

While we've only examined tubes, transistor amplifiers follow the same general rules. **Fig. 6** tabulates the characteristics of the various types of grounding for both tube and transistor amplifiers.

Common ("Grounded") Element	Input/Output Ratios Voltage	Current	Impedances Out	In	E	—Gain— I	PWR
Vacuum Tubes							
Cathode (Normal)	>1	>1	Med	Med	Good	Good	High
Grid	>1	$\leqq 1$	Low	High	Good	None	Med
Plate (Cath. Foll)	$\leqq 1$	>1	High	Low	None	Good	Med
Transistors							
Emitter (Normal)	>1	>1	Med	Med	Good	Good	High
Base (Early CKTS)	>1	$\leqq 1$	Low	High	Good	None	Med
Collector (Emitter Follower)	$\leqq 1$	>1	High	Low	None	Good	Med

Fig. 6—General characteristics of the three different types of amplifier circuits are listed above for both tubes and transistors. Notice that circuit characteristics are determined by in/out ratios of voltage and current, more than by choice of tube or transistor. All comparisons assume that the same tube type or transistor type is used in the various circuits, of course. A low-gain tube with grounded cathode may have less gain than a high-gain tube in grounded-grid arrangement, still.

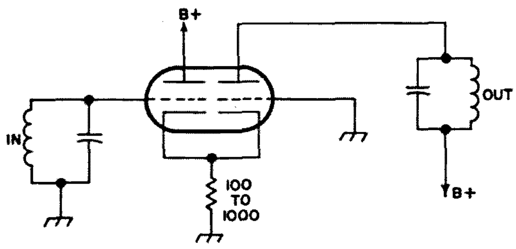

Fig. 7—Cathode-coupled amplifier consists of cathode follower stage (at left) direct-coupled to grounded-grid stage (right) with common cathode resistor. Almost any twin triode can be used; for RF use the TV-tuner types are recommended. Circuit can also be used for audio by using resistor-capacitor input and output coupling rather than the tuned circuits shown here. Circuit provides low noise of triode, gain equal to a single stage, and does not require neutralization.

What Limits An Amplifiers Usefulness? Amplifiers can be "cascaded", one after another, with the output signal of each furnishing the input signal to the next stage.

It might appear that any number of amplifier stages could be cascaded, to get any amount of gain we might want. This isn't the case, however. There are definite practical limits to the number of stages which we may cascade, and some good reasons for those limits.

The extreme limiting factor is "noise". Any substance at a temperature greater than absolute zero—which means anything at all that exists in the real world—has at least a few electrons in motion in it. They're jittering about because of the energy of heat, which is present in everything.

The exact number of electrons in motion at any instant, and their direction of motion, is totally unpredictable; it's something like trying to predict which kernel of corn is going to pop next in a corn-popper. Since we cannot predict it, the electrical energy which results from this random motion of electrons is called "noise"—and as we have seen, everything has at least some electrical noise present in it.

If we have several amplifiers, each with very high gain, and connect them in cascade with each other, we will quite rapidly reach a point at which the noise present in the input circuit of the first stage will provide all the output signal which the final stage can accept. Any input signal at all, under these conditions, would overdrive the cascaded amplifiers. Obviously, such an arrangement would not be usable.

In practice, we reach the limit much sooner. As soon as the amplified noise reaches an objectionable level in the output, we have all the amplification we can make use of. This condition is usually reached by the time we stack three or four stages in cascade with each other, if each stage has "normal" gain.

The noise also sets another limit—it determines the weakest input signal which we can locate. Any signal weaker than the noise cannot ever be made stronger than the noise, because any amplification which we apply to this signal will be applied to the noise as well.

This is the reason that we find so much emphasis on "low-noise" amplifiers for VHF reception and for high-quality audio work; they permit weaker signals to be used.

Any practical amplifier also has a limitation in the bandwidth it will handle. While we can build amplifiers to operate with dc signals, they're tricky; most amplifiers work only on ac, and use coupling capacitors to isolate the stages from each other so far as dc is concerned.

These coupling capacitors establish a lower limit on the amplifier's frequency range. When the reactance of the coupling capacitor is equal to the input impedance of the next stage, half the signal will be lost in voltage drop across the capacitor, and as a result the signal will get only half the amplification which a higher-frequency signal would get.

In addition, all practical amplifiers have stray capacitance in parallel with the input and output circuits.. This stray capacitance shunts off some of the output signal. So long as the reactance of the stray C is much higher than the impedances designed into the circuit, this has little effect—but as the signal frequency goes up the reactance of the stray C goes down, while the designed-in impedances tend to remain constant. This means that more of the signal is shunted off to ground, and again less output is obtained than we would expect.

The result is that any practical amplifier has a closely defined operating bandwidth. The low limit is set by the interstage coupling capacitors, and the upper limit by the impedances in the circuit and the amount of stray capacitance.

The bandwidth effect, also, is cumulative as stages are cascaded. At the low-frequency

end, if each stage is giving only half the amplification we would expect, then two stages would give ½ x ½ or ¼ the amplification we would expect, three stages would give only ⅛, and so forth. At the upper end, the same type of action occurs. The bandwidth of a multi-stage amplifier, then, is usually much less than that of any one of its stages.

This last statement is not always true. If all the stages except one are designed to cover a very wide bandwidth, while the one exception has narrow bandwidth, then the narrow-band stage will establish bandwidth for the entire amplifier. This situation is frequently encountered in hi-fi amplifiers, but seldom in radio applications.

How Can The Limits Be Stretched? The history of amplifier design is largely a history of successive, successful attempts to stretch the operating limits of existing amplifiers. Early vacuum-tube amplifiers had limited gain, narrow bandwidth, and were difficult to adjust. Today's circuits, while based on the same theoretical principles, can provide more gain than we can use, almost unlimited bandwidth, and virtual total freedom from adjustments.

The major limiting factors, as we have seen, are those of noise and of bandwidth. Another factor, which we didn't discuss previously because it is relatively unimportant with modern tubes and careful circuit layout, is that of unintentional feedback. The problem of unwanted feedback and techniques of neutralization were covered in the "feedback" installment of the Advanced Class course; they apply equally here.

The grounded-grid amplifier circuit employs the grid of the tube as a shield between input and output circuits to reduce the feedback problem—but it adds a new one of its own in the form of its abnormally low input impedance.

To counter this, the "cathode-coupled" amplifier circuit was developed. This circuit, shown schematically in **Fig. 7**, is essentially a cathode-follower to transform a high input impedance down to a low value without voltage gain, coupled directly to a grounded-grid stage. The grounded-grid stage provides voltage gain.

The cathode-coupled circuit works extremely well, and combats not only feedback but also the noise problem. Triode tubes inherently have less noise than do tetrodes

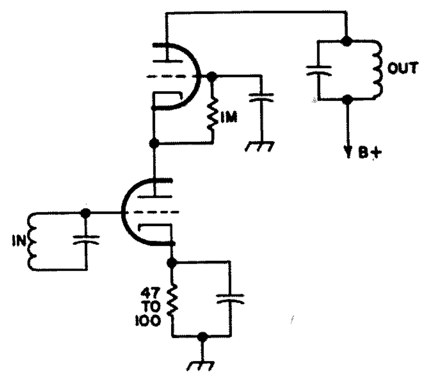

Fig. 8—Cascode circuit shown here replaced cathode-coupled arrangement in most applications, since gain is higher while noise is equally low when same tubes are used. Lowest noise is obtained if neutralization coil is added between plate of lower half and cathode of upper, but performance is usually adequate without coil as shown. While circuit is usually employed as RF amplifier, it also may be used at audio by changing input circuits accordingly.

and pentodes; each additional element introduces additional noise. The cathode-coupled circuit made it possible to use a twin triode in place of one pentode, and obtain approximately the same gain with far less noise.

A somewhat similar circuit, developed during World War II at the Radiation Laboratory of M.I.T. for radar use, surpassed the cathode-coupled amplifier in performance and rather rapidly supplanted it.

This circuit, shown in **Fig. 8,** is again a pair of direct-coupled amplifier stages with a grounded-grid output stage, but the input stage is a conventional grounded-cathode arrangement rather than a cathode follower.

The first stage is prevented from oscillating or being affected by feedback because its load is the low impedance of the grounded-grid circuit; the gain is too low for oscillation. However, even so the gain is greater than that of the cathode follower, and so the gain of the two tubes amounts to that which the two tubes would provide were both used as grounded-grid (or four used as cathode-coupled) stages.

The series circuit of **Fig. 8** is the final development stage; originally, shunt feed was used and the circuit was considerably more complicated.

This circuit, consisting of two tubes *cascaded* to produce the performance of a pent*ode*, was dubbed the "cascode" circuit

by its inventors, and is still widely used under that name.

While its main application is as a VHF *rf* amplifier, the cascode circuit is also sometimes used as an audio amplifier. Gain depends primarily upon the load seen by the second stage, and if the variant shown in **Fig. 9** is used as much as 2000-time voltage amplification may be obtained in a single cascode circuit. In this version, the added parallel resistor permits additional current flow through the "lower" tube section, keeping its gain high, while the extra-high valued load resistor of the "upper" section produces a wide voltage swing.

The problem of adequate bandwidth is attacked by many approaches. One of the most common is to use lower-than-normal load impedances; this reduces the effect of the unavoidable shunting stray capacitance and so extends the frequency limit of the amplifier upwards. As the load impedance is reduced, however, the gain per stage goes down accordingly and so more stages are required to get the same gain. Fortunately, the resulting narrowing of bandwidth because of added stages does not quite cancel out the improvement gained in the first place. It's not uncommon, though, to find eight to ten stages in a wide-band amplifier, providing about the same gain you would get from two or three narrow-band stages.

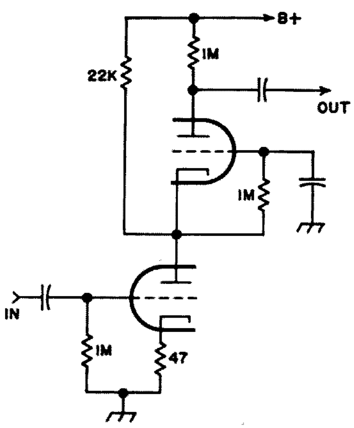

Fig. 9—This variant of the cascode circuit provides ultra-high gain, surpassing that normally obtained with pentodes. Extra-high load resistor in output circuit is responsible for high gain; 22K resistor shunting entire upper stage is necessary to provide adequate current for lower stage. Output impedance of this circuit is also very high and as a result high-frequency cutoff is usually rather low (below 3 kc). Third triode may be added as cathode follower to overcome part of this problem.

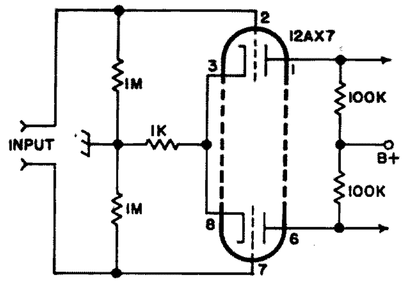

Fig. 10—Differential amplifier, often called simply "diff amp" in industry, is capable of DC amplification with relatively simple circuits. Circuit amplifies only the difference *between the input signals, and so cancels out any signal which appears on both input leads at same time in same polarity (such as hum or DC shift in power supply levels). Balance is maintained by common cathode resistor. Potentiometer may be added at junction of load resistors, with B+ applied to arm of pot, to permit static adjustment of balance as well.*

At the other end of the frequency limit the problem is somewhat different. As interstage coupling capacitors are made larger to permit improved low-frequency response, the amplifier's action in recovering from brief overloads gets progressively worse. The point is finally reached at which the amplifier requires several seconds to recover from a millisecond-long overload.

The coupling capacitors can simply be eliminated to provide response all the way down the frequency scale to, and including, dc. When this is done, though, any small change in power-supply voltages or tube characteristics is seen by all the following stages as a signal to be amplified. Because of this, a dc amplifier is much more tricky to keep operating properly.

One circuit widely used to overcome the instability problem of the dc amplifier is based on the idea that the two halves of a single tube change at about the same rate, and changes in power supply levels cannot hurt the signal if they are made to cancel themselves out. This circuit, the "differential" amplifier, is shown in **Fig. 10.**

In the differential amplifier, the signal to be amplified is applied, push-pull fashion, to the two grids. Each half of the amplifier stage operates essentially independently—but the output is not taken from plate to ground of either half. Instead, the *difference* in output levels between plates is used as the push-pull output signal.

Any change of power-supply levels affects both plates at the same time, and has little effect upon the *difference* signal. Similarly, any change of tube characteristics which affects both halves of the tube is also cancelled out.

By using the common cathode resistor, the cathode current of each half of the stage feeds back some of that half's signal to the other half. This improves the circuit's action greatly, because the feedback can occur only if *un*balance is present (if the amplifier is working as intended, the total cathode current remains constant—any increase in current in one half is offset by an equal decrease in the other half). Thus the desired difference signal is free of feedback, but any undesired components in that signal due to circuit unbalance are reduced by the feedback.

This self-balancing works so well that the circuit may be used to create the push-pull signal required, from a single-ended input. All you have to do is tie one grid to ground, and feed the desired signal to the other grid. The automatic balancing will put the proper input signal on the grounded-grid side, to produce the properly balanced push-pull output signal. Such a version is often found in hi-fi equipment, and also in sophisticated test equipment.

If the cathode resistor is returned to a negative supply of voltage approximately equal to the positive plate supply, several stages of differential amplifiers can be cascaded with all signal reference being to actual ground. This approach is almost a standard approach in lab oscilloscopes of the medium-performance class (top-grade instruments use different and much more complex amplifiers).

Next Month. VHF interest is consistently high; so are the problems of TVI. Since most TV broadcasting, and all ATV activity, is in the VHF region and above, we'll combine these subjects and explore them in our next installment. ■

Wayne Green

With Kayla getting married and moving to Florida, I'll be back in the editor's chair after about four years of rest. I hate to see her go. Few hams know the good and the bad guys in ham radio as well as Kayla. We'll miss her perspective. Your letters were at first skeptical that a YL could turn out a good magazine in what is, essentially, a man's hobby. Once she got out from underneath the problems left by her predecessor the letters turned to raves.

In the last four years, 73 has been growing healthily. Our circulation just about doubled during the period while the circulation of the other ham magazines dwindled. Our basic format of concentrating on articles and more articles rather than filling up the magazine with low-cost monthly columns and contest reports seems successful. Our editorial policy of telling just what is really going on and how we feel about it seems popular with just about everyone except our fellow publishers.

From a one-man editorial staff we have grown to a whole team and are now setting all of the type for both the articles and ads in 73 in our typesetting department. Our art department has a number of illustrators preparing our schematics. Our production department is turning out not only 73, but is working on a whole line of new books. The Coax Handbook is the first of these and the Advanced Class Study Course is the second.

Our advertising department, headed by Bill Beatty, is doing quite well, but even so, Bill could use a little help from you. If you prefer to read a magazine that is made up of articles rather than columns and reports, then you should let the manufacturers and distributors who advertise in the ham magazines know where you are looking for their ads. If we had 50 pages of ads we could bring you a 200 page magazine every month with about 150 of them devoted to articles. If you'll look back you'll find that the last 200 page issue of QST had 68 pages of ads and only 34 pages of articles! The rest was activity reports and columns. You can vote for the magazine of your choice by letting the advertisers know where you want to see their new products and specials.

The articles in 73 will start to reflect my own interests again...VHF, DX, RTTY, FAX, contests, and a multitude of construction projects. I have some fabulous goodies in store for you. We'll emphasize antennas in May, VHF in June, mobile in July, transistors in August, transmitters and linears in September, receivers in October and transceivers in November. Our policy of paying the fastest and the mostest for good articles is giving us the pick of the articles and I could easily fill a 200 page magazine every month for you if you could just get the advertisers to back us up.

We are by far the most particular about who our advertisers are and if we get many complaints we bounce 'em until things are straightened out again. Some of the advertisers that are not in 73 are not in there because we will not accept their ads. You can get a good clue to this by checking for some that we have dropped in the last year or so. The readers of another magazine, one which brags about checking their advertisers, lost thousands of dollars to a crooked outfit from which we refused to accept advertising.

73 has grown beyond anything that I expected. Perhaps it is getting too big for me. Sometimes I wonder if we should go public and issue stock. Or perhaps we would do better to join one of the larger publishing houses and let them handle the business end of things. When a business gets this big there isn't enough time left for hamming. I miss that most of all.

It would be nice to be able to get away for a long trip to some relatively remote part of the world and DX a bit. We have all too few amateur DX-peditions. I see that Gus is off again, but Gus is a professional DXer and you have to pay him for working him, one way or another, or else he won't go. This was one of the big difficulties with Don Miller. I don't put much store in the claims that a professional DXer can cage upwards of $50,000 a year in relatively tax-free donations, but there obviously is enough in it to keep one or two fellows on the road year in and year out. If it didn't pay they wouldn't do it.

And, once a fellow is off DXing for a business he is forced to find new places to oper-

(continued on page 67)

Editorial Liberties

Apparently I stepped on some toes with my February Editorial Liberties. I dared to suggest that ARRL's OO program might be more effective in the policing of our bands and in recommending that FCC take action against malicious offenders. That segment of the ham population which is opposed to ARRL has been most vociferous in it's opposition.

I'm going to ask two questions, and then try to answer them. The first is: Why ARRL? And, the second: Why has it failed?

The answer to the first is fairly simple. It was obvious many years ago that amateur radio could not stand without an organized body to support it. A look at the Constitution and By-Laws, shows that it is organized along Democratic principles. You elect the person you feel will best represent the interests of your group, and then guide him in those interests. Your Director's job is to take action according to the member's wishes. It works very much like our Federal Government. The voters elect their representative to the Congress, who in turn cast their votes according to the way their constituents tell them to.

The answer to the second question is even more simple. It can be said in one word... "YOU." Back in 1933, a man named Hitler took over Germany. Even long before, a man named Lenin took over Russia. Today, we have our Castro, our DeGaule, our lesser dictators; and why? Because the people really didn't give a darn. They allowed it to happen. ARRL has a fine principle. ARRL has a fine constitution. ARRL could be the democratic voice of amateur radio. Instead it is a closed corporation of people who live for ARRL rather than amateur radio.

Now, I'm going to ask some questions which I am unable to answer. Only you, the reader can answer. Are you a voting member of ARRL? Did you cast a vote in the last election? Do you know the name and address of your Division Director? Did you write to him before the deadline for the coming Board meeting in May? If the answer to any of these questions is "NO," you have no right to criticize. Sitting back and grumbling that things are not going your way won't get you anywhere. The only way to make ARRL work for you is to become involved.

The Ansel Gridley case in Florida is still going on. Grid, W4GJO, is being sued for one million dollars. The plaintiff, who owns a large liquor store in Sarasota, has been advertising in local newspapers with vitriolic anti-ham messages. He has also distributed bumper stickers like the one shown below. Grid has obtained an injunction to prevent further ads or stickers, but if you have ever tried to remove one of those stickers, you know they will be around for a long time. I suggest that large clubs (certainly ARRL won't get involved) should file counter suits against this man for defamation of character in the amount of three million.

With this issue, I sing my "Swan Song." My 22 months with 73 has been rewarding and exciting. However, my forthcoming marriage to K4MWS promises to also be rewarding and exciting and the only deadlines to be met will be mealtimes. We are to be married in May and as soon as I have settled in my new home in Florida and have my feet back on the ground, I will continue as a contributing editor for 73. Thank you all for both your criticisms and your support.

Kayla...W1EMV

Dual Channel Oscilloscope Preamp

Robert G. Teeter
16 Poplar Drive
Rochester, N.Y. 14625

Upgrade your present oscilloscope to have dual trace capability. Don't buy a new scope, instead build a preamp that has the features you want and need. Two channels, each with a separate attenuator, can be displayed one at a time or alternately. The scope sync can be triggered from either input.

The heart of the unit described herein, the switcher and driver boards, were originally designed as part of a systems modification. Seventeen Tektronix 360 type indicators (3 inch oscilloscopes) were converted to dual trace operation. Each oscilloscope was modified internally by adding a pedestal switching transistor, pedestal adjust potentiometer, and 10x amplifier. The switcher boards and driver boards were located on a relay transfer panel under the console. The mode switch and individual gain controls were mounted on the operator's control panel.

By building a switcher board and a driver board and adding some switches and accessories, a good alternate trace preamp can be constructed at moderate cost. The required accessories include power of plus and minus 12 volts, a mode switch and knob, and individual channel gain controls. Optional accessories would be frequency compensated attenuators, switched trigger output and an amplifier. A small modification is required within the oscilloscope itself. The block diagram, **Fig. 1**, shows the general relation of the parts.

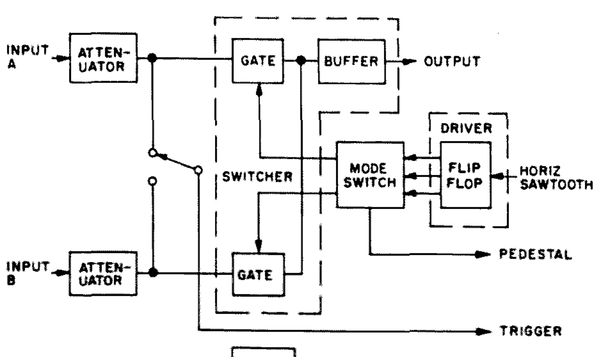

Fig. 1

This is not a step-by-step construction article. Schematics, parts lists, and a description of each circuit will allow anyone who has built from scratch to complete a working unit.

Packaging

Depending on individual desires this unit may be packaged in many ways. First, it could be built entirely within the oscilloscope, if enough front panel space is available for the switches. Secondly, it could be built into a small utility box with one cable, to a suitable connector on the scope. In this case the following functions either go into or come out of the scope (a) 6 Vac for power, (b) horizontal sawtooth, (c) pedestal drive, (d) output and (e) trigger, if the individual trigger is desired. See **Fig. 2**, front panel layout.

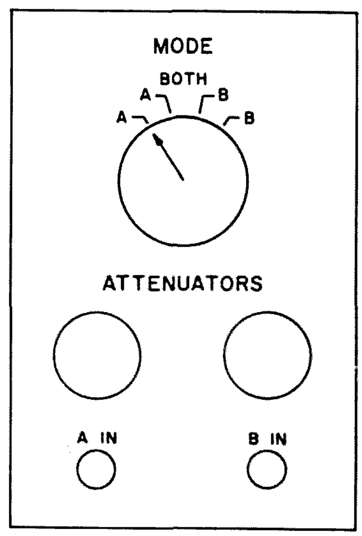

Fig. 2 Panel layout

Power

Power requirements are both plus and minus 12 volts dc at less than 50 mA. Power may be obtained from batteries, a conventional double dc power supply as in **Fig. 3** or from the 6 Vac filaments of the oscilloscope. If the filament supply is used then two voltage triplers and regulating zener are required, as in **Fig. 4.** The voltage triplers eliminate the necessity for a heavy

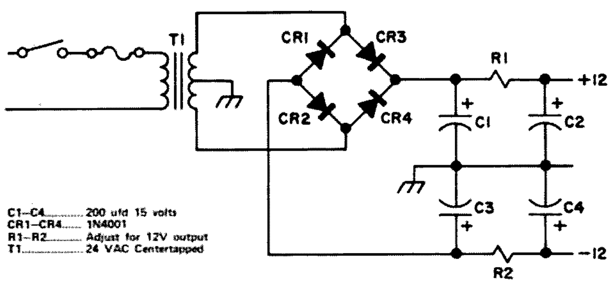

Fig. 3

power transformer, and good regulation is obtained with the zeners. In addition power comes on automatically any time the oscilloscope is turned on.

Switcher board

The switcher board is the heart of the dual trace preamp, Schematic, see **Fig. 5.** Seven Texas Instrument field-effect-transistors are used to alternately pass one signal to the output. For example, if pin F is low and H is high, channel one appears at the output, pin L. If the voltages are reversed, pin F high, pin H low, then channel two appears at the output. Q1, Q4 and Q5 are buffers. Q2 and Q6 are series switches and Q3 and Q7 are shunt switches. The off channel is suppressed more than 70 db.

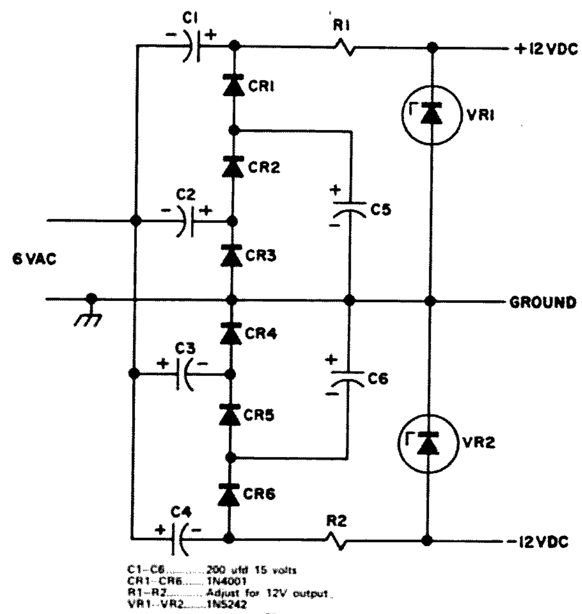

Fig. 4

R14 is used to adjust the output level and R5 adjusts dc balance. If both inputs are connected to ground, then the output, as seen at pin L should be a straight line, not a square wave. Note that to see this another oscilloscope would have to be used, or the pedestal drive to the scope would have to be removed. See discussion under pedestal.

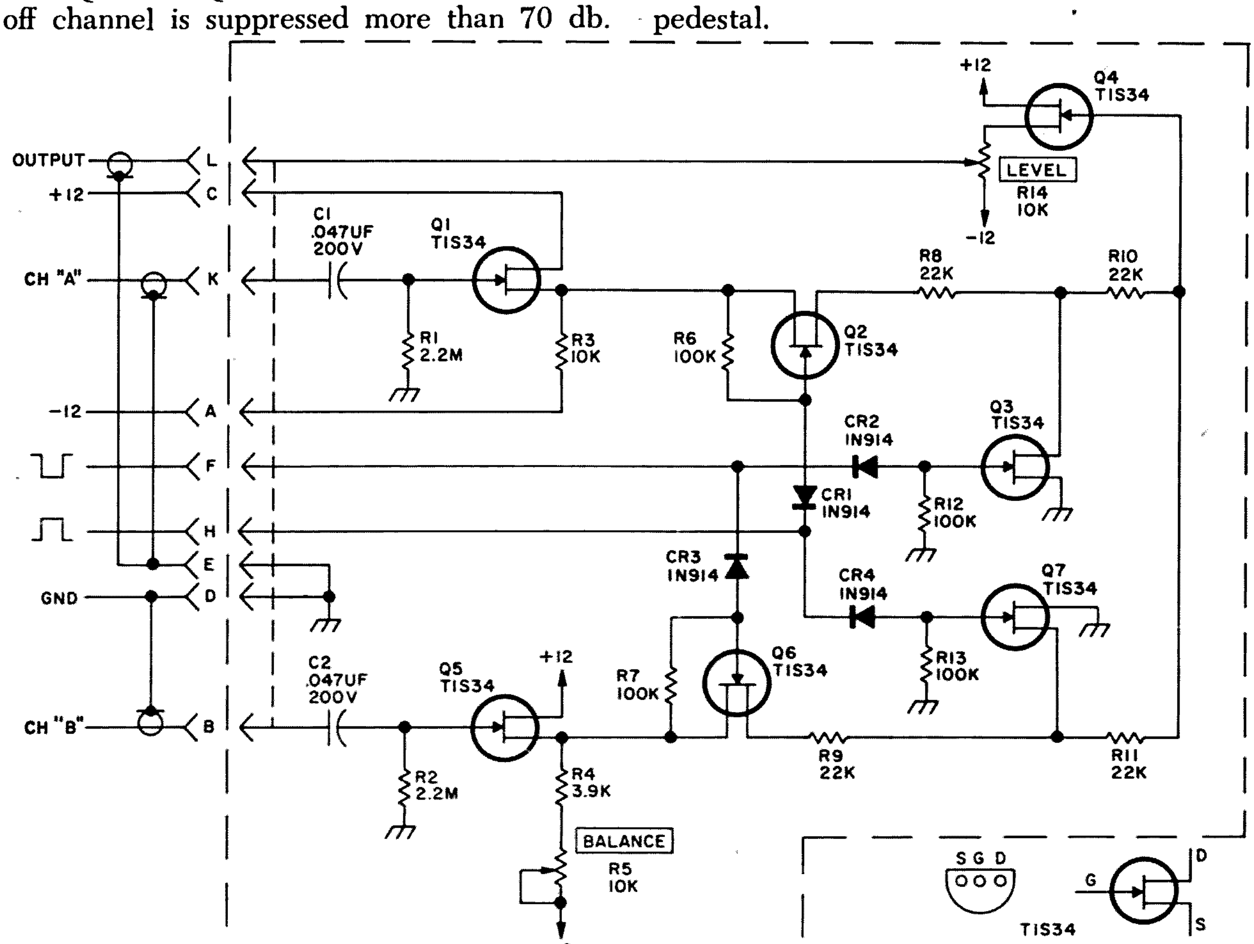

Fig. 5

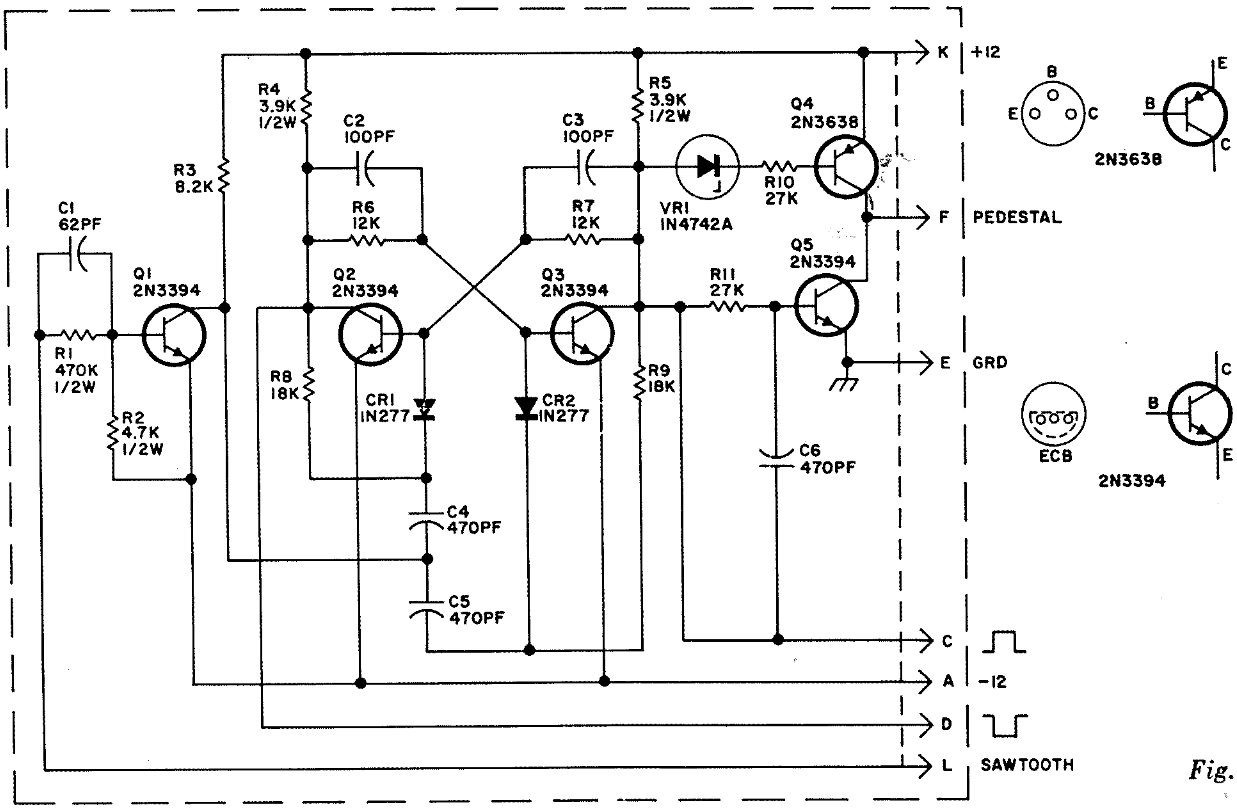

Fig. 6

Driver board

The driver board is basically a flip-flop triggered by the scope horizontal sawtooth. **Fig. 6** shows the schematic. Q1 is a saw shaper. Q2 and Q3 constitute the flip-flop and outputs are taken for gating the switcher board. Q4 and Q5 form the pedestal driver to position the beam on the scope. In conjunction with the circuit discussed under pedestal, the beam is made to go up for channel one and down for channel two, thus the traces are separated on the face of the tube. The driver will switch acceptably for a sweep speed greater than 5 microseconds per centimeter. The inherent rise time of the pedestal, which is the limiting factor, is about 1 microsecond.

Mode switching

The switch positions shown in **Fig. 7** include channel A only, B only, and both, triggered by A or B. It is necessary to switch 4 functions, (a) 2 switcher lines, (b) pedestal line and (c) trigger line.

Pedestal

The internal modification to the scope consists of two parts as shown in **Fig. 8.** First, a connection is needed to the horizontal sawtooth for triggering the driver board. Use caution here as this voltage may be between 100 and 300 volts. This lead should be run in coaxial cable such as RG-174/U. The pedestal lead should also be in coax. The transistor, Q1, causes one side of the push-pull vertical amplifier to be unbalanced, shifting the position of the trace on the screen. Switching occurs pretty much during the sawtooth retrace period. The existing vertical centering control will move both traces equally, while the pedestal adjust control will move only the lower trace.

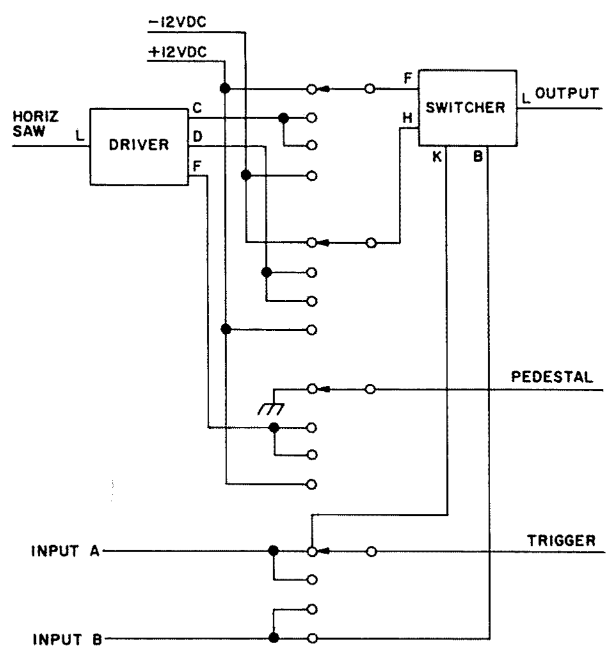

Fig. 7

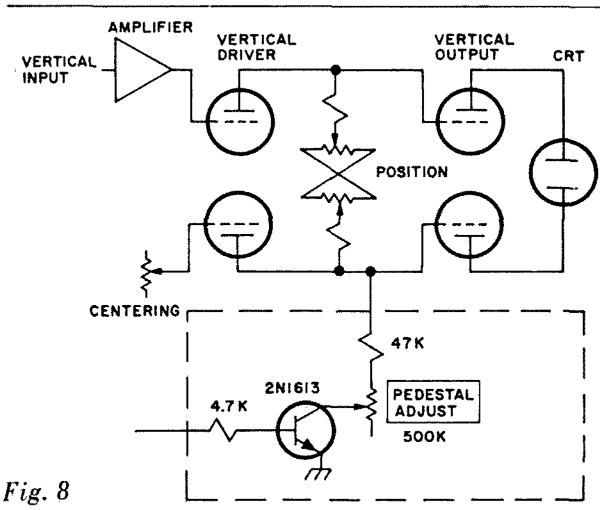

Fig. 8

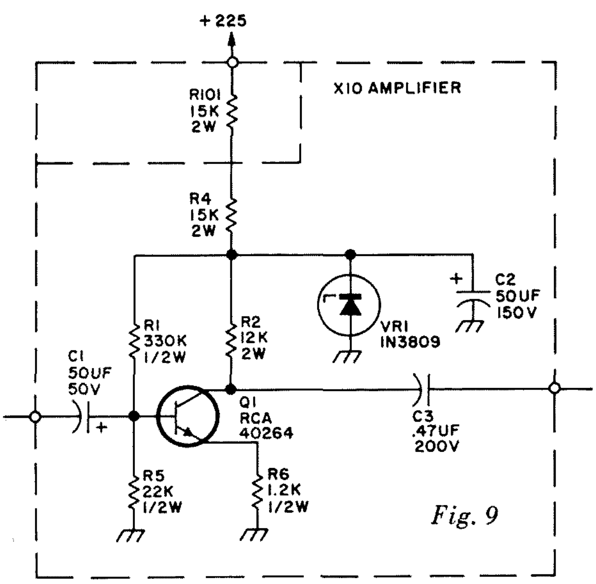

Fig. 9

(Upper trace if you get polarities reversed anywhere.) If it is desired to overlap the traces an easy way to accomplish this is to use a pot that has an on-off switch. Connect the on-off switch between the collector of the transistor and R2.

Attenuator

The attenuator can be a simple potentiometer or a calibrated 10 step attenuator as described in the *Electronics World* article by Donald R. Hicks—"Designing an Oscilloscope Vertical Attenuator." The only requirement is that each input signal to the switcher board be less than about 15 volts peak-to-peak. Otherwise clipping will occur in the FET's.

Amplifier

If desired an amplifier can be added. The amplifier used in the Tektronix modification is shown in **Fig. 8.** This was required in the system modification as the original single attenuator in the 360 indicator was to be used to control both signals. Uncalibrated gain controls were used to vary the levels individually. When the individual gain control was at maximum the original attenuator read correctly.

Printed circuit board availability

Etched and drilled boards are available. Please correspond with author at 16 Poplar Drive, Rochester, New York 14625.

Simplest rf Preamp

Jim Ashe, W1EZT

How simple can a transistor circuit be? Here is a basic *rf* preamplifier, usable from low frequencies to VHF, that must come very near the limit. It looks too simple to work, in fact, but it will do a good job in SWL, VHF, and TV preamplifier applications. Yet it does not compromise in the important bias-stability department as many simple circuits do, and it will accept silicon and germanium transistors interchangeably. The few components can be assembled in almost any convenient style provided the circuit is built on a piece of PC board for good grounding.

The emitter-biased amplifier

We rarely see emitter biasing in experimenter and radio amateur circuits. Perhaps this is because the circuit needs two voltage supply polarities when used in its simplest form. Yet sometimes it is not so hard to use a second battery if the current requirements are low, and a few years ago electronic circuits were expected to need several voltages. Getting by with a single power supply voltage is something of a luxury, which we can exchange for the convenience of a really simple circuit, untroubled by the bias problems often seen in amateur-built gear.

In most of the commonly-used electronic circuits the transistor properties enter into the biasing design. There must be biasing, because the standing bias voltages and currents energize the transistor, and provide power for it to use in amplifying its input signal. But there is one way in which we can bias a transistor which allows the transistor practically no control over its collector current. Using this arrangement eliminates transistor aging, temperature, and replacement effects. We can pull a germanium transistor out of its socket, replace it with a comparable silicon transistor, and discover the circuit works about as well in either case. Very convenient! Specially nice for the hobbyists who must make do with what they have on the bench, or are able to scrounge out of some miscellaneous circuit board.

The complete circuit appears in **Fig. 1.** Although it is a very interesting circuit to industrial designers, unlike many other advanced circuits its basic workings really are simple. Suppose battery B2 is disconnected but B1 remains in the circuit. What happens? A current flows through R1, into the transistor emitter terminal, to the transistor base terminal, and to ground. If the emitter-base diode properties change due to aging or replacement with a different transistor, the current will change only slightly. Using a silicon transistor, there would be only an 8.5% increase in current if we shorted the emitter-base junction. No transistor replacement or type changing, even from silicon to germanium, could produce as large a change as this. Any variations over time in circuit performance must be caused by something other than bias instability.

Now, if we complete the collector circuit by connecting battery B2, the collector terminal will steal the emitter current before it can flow to the base terminal and to ground. The emitter current is practically unchanged, and for ordinary amplifier applications we can ignore the tiny change in emitter-to-base voltage that appears when the collector terminal is energized. This is why emitter biasing is extremely simple and stable. The transistor current is controlled by one single resistor in the emitter circuit rather than by a network jointly including emitter, base, and possibly collector terminals.

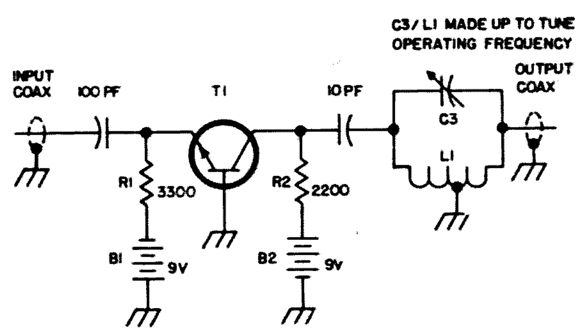

Fig. 1 Complete circuit of the rf preamplifier. Parts values are not critical.

This isn't the best circuit for some applications, and is specially inappropriate for power-amplifier designs. But it works very well indeed for small-signal *rf* preamplifier application because *rf* circuits can easily meet the low input-impedance and high output-impedance requirement set by the transistor characteristics. At audio we would have to use iron-core matching transformers, but at VHF a few self-supporting turns of inexpensive wire will do the job.

A large capacitor, CI, connects the low-impedance input cable to the transistor emitter terminal without upsetting the bias arrangements. Its capacitive reactance should be only a few ohms at the *rf* operating frequency. The values in **Fig. 1** were chosen for operation on the 2-meter amateur band, and the 100 pF capacitor CI has a reactance of around 10 ohms. A 220 pF capacitor might have been a better choice but those available at construction time were not very small.

The collector circuit is a simple shunt-fed resistor-loaded connection via another blocking capacitor to an inverted pi output coupling network. The reactance of C2 at 2 meters is around 100 ohms, much less than the 2200 ohms resistive load or the load coupled back from the output cable. This capacitor, and CI, serve only to prevent outside connections from upsetting the dc conditions in the circuit, and their values are not critical. You should avoid too-large capacitors since these contribute nothing to circuit performance, cost more, and increase the possibility of unwanted resonances.

If we turn a pi-tuner inside out, what do we have? Instead of one inductor and two capacitors with the connection between the capacitors grounded, we have a single capacitor (C3) across the ends of an inductor (L1) which has a grounded tap. We can look at this arrangement as a resonated autotransformer, in which the unwanted coil reactance is balanced out by the parallel capacitor and the impedance transformation from 2200 ohms input to 52 ohms output is determined by the turns ratio on the two sides of the grounded tap. In this case we have six turns grounded at turn #1 from the cable end, which transforms the 52 ohms to roughly 1260 ohms, approximately. The impedance transformation is the square of the turns ratio.

Construction

The construction style is not printed circuit, although the preamplifier is assembled on a piece of copper-clad PC board. There is no transistor socket simply because we can get by without one. This minimizes lead lengths and inductances, and the base lead is soldered directly to the PC board. An input coax connector is eliminated by soldering the braid of the coax input cable directly to the board. Blocking capacitor CI is soldered directly from the transistor emitter lead to the center conductor of the cable.

At the output, LH side, a pair of lugs mounted in the board support the inductor of the output matching circuit L1/C3. The lugs could be replaced by a pair of tiny insulated stand-offs, or a small terminal lug strip to avoid the need for removing some copper. In this case it was easy to solder the small mica compression trimmer C3 between the lugs on the opposite side of the board. The output blocking capacitor C2 is mounted between the transistor collector lead and the input end of the matching network, and the output coax cable center conductor is soldered to the lug supporting the output end of the network. With the cable outer braid soldered directly to the copper surfaced board, another *rf* connector is eliminated.

When I originally built the preamp, I connected the coil to ground a little too far to the right hand side of the coil. This didn't work too well and I had to move the tap to the left. This connection can be moved up or down the coil for best gain, and should not be so far along the coil toward the transistor that the tuning capacitor seems to have no effect.

Resistors R1 and R2 extend directly from emitter and collector leads to convenient lugs situated far enough from the transistor to avoid power lead capacitances from affecting the circuit performance. These resistors are half-watt units but quarter-watt units would work as well. Composition resistors are preferred, rather than metal-film or wire-wound variety.

Operation

Complete the circuit assembly (which may require several minutes) without making the connection from collector to output network L1/C3 via C2. This prevents transistor collector-base diode action from killing coil Q when you try to tune it to frequency using a grid dip oscillator, and it may pre-

vent damage to the transistor too. If you do not have a GDO use coil and resonance equations or nomographs, and provide lots of adjustment. When you reasonably believe the output LC circuit resonates near to or a little above the operating frequency, go on to the next step.

Connect a 56 or 68 ohm half-watt or smaller composition resistor across the preamplifier input terminals, and make the collector battery connection through a milliammeter. There should be no current flowing. Upon completing the emitter battery circuit, the collector current should rise to about 2.6 mA and a VTVM or 20,000 ohms per volt multimeter should indicate about 3 to 4 volts at the collector terminal. Base-emitter voltage should be around 0.3 volts for a germanium transistor, or 0.7 volts for a silicon transistor. If you do not find these voltages check first to be certain battery polarity connections are correct. If you've goofed don't replace the transistor, it's probably all right. Switch polarities and try again.

Now complete the collector-to-output connection through C2, and install the preamplifier in your receiver system. Turn it on and listen for birdies. If there are signs of unwanted oscillation replace the input circuit with a 68 ohm composition resistor and if the birdies remain then move the coil tap nearer to the collector terminals. This increases transistor loading and reduces circuit gain. If you find the preamp oscillates with antenna input but does not with a 68 ohm resistor across its input, then you need to improve your antenna system. It's reactive and needs tuning or corrective mechanical work.

Finally, tune C3 for maximum output. In a TV weak-signal area this will appear as a sharper, stronger picture, and in SW and VHF applications you will observe stronger signals and less noise unless your system noise comes from locally generated interference, in which case there may be more of it.

Additional suggestions

We can easily make this simple circuit more complex. For instance, we can replace CI with a small compression trimmer, adjustable to tune out the small inductance of the cable-to-transistor-and-return loop. This will improve circuit stability by reducing the fedback voltage that collector-to-emitter capacitance can develop from emitter to ground.

We can also improve circuit gain by replacing R2 with an rfc. This choke should have a reactance of several ten-thousands of ohms at signal frequency. 100 MH at 6 meters and maybe 30 at 2 meters looks about right. Then the output matching network can be readjusted for a greater impedance transformation, and signal gain will be increased. Chance of oscillation will increase too, but this arrangement offers an interesting possibility.

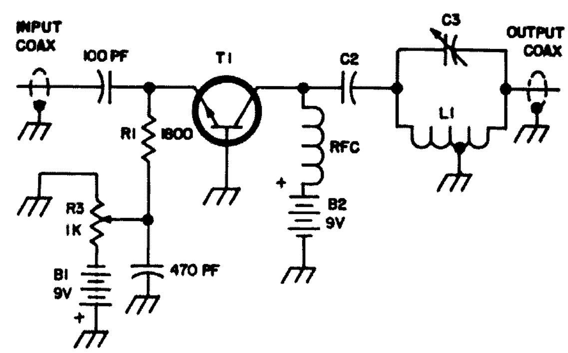

Fig. 2. Suggested variation for improved performance. Operating current may be varied for strong or weak signal work without detuning the output circuit.

With no collector resistor, collector voltage no longer depends upon collector current. We can now adjust collector current by adding a variable resistor in the emitter circuit, which will vary the amplifier operating conditions without detuning the collector circuit. See **Fig. 2.** This circuit is certainly more elaborate than the simple one you may have constructed first, but enables you to choose increased collector current at lower gain to reduce cross-modulation effects, or to adjust the emitter current for maximum gain to hear weak signals.

George Leonard
Associate Editor
Look Magazine

Education and Ecstacy

The following is reprinted by permission of *Look Magazine* and Mr. Leonard. I think this last chapter of his book describes the "magic" quality of amateur radio.

LIFE HAS ONE ultimate message, "Yes!" repeated in infinite number and variety. Human life, channeled for millennia by civilization, is only just beginning to express the diversity and range of which it is easily capable. To deny is to swim against the current of existence. To affirm, to follow ecstasy in learning—in spite of injustice, suffering, confusion and disappointment—is to move more easily toward an education, a society that would free the enormous potential of man.

When men must serve as predictable, prefabricated components of a rigid social machine, the ecstatic is not particularly useful and may, in fact, erode the compartments so necessary for the machine's functioning. But when a society moves away from the mechanistic, when an individual functions as a free-roving seeker, when what we now term "leisure" occupies most of his hours, ecstasy may usefully accompany almost every act. Technology is preparing a world in which we may be life-long learners. In this world, delight will not be a luxury but a necessity.

I can recall little of what happened in school the winter I was 15. Perhaps that was the year everyone in my English class had to do a chapter-by-chapter synopsis of *Treasure Island*. But the afternoons and nights of that period still are vivid. I was infected with the ham-radio bug. My next-door neighbor, a boy two years older, had got me started, and I lived for months in a state of delicious excitement. I would rush home from school, knowing the day would not be long enough. I would work steadily, practicing codes, devouring ham manuals and magazines, pouring over catalogues of radio parts, building simple shortwave receivers. I loved everything about it. When I read Gerard Manley Hopkins's *Pied Beauty,* the phrase, "all trades, their gear and tackle and trim," immediately summoned up the coils and condensers, the soft-glowing vacuum tubes, and sizzle and smell of hot solder, the shining curls of metal drilled out of a chassis.

One night, my radio experience came to a moment of climax. For weeks, I had been working on my first major effort, a four-tube regenerative shortwave receiver. The design was "my own," derived from circuits in the manuals and approved by my knowledgeable friend. Every part was of the highest quality, all housed in a professional-looking, black-metal cabinet. Every knob and dial was carefully positioned for efficiency and aesthetics, and there was an oversized, freewheeling band-spread tuning knob. That night, I had been working ever since running most of the way home from school. I had skipped dinner, fiercely overriding my parents' protests. Now, at about 11 o'clock, I soldered the last connection.

With trembling hands, I connected the ground and the antenna, plugged in the socket and switched on the set. There was a low, reassuring hum, and, after a suspenseful wait, the four tubes lit up. I increased the volume. Dead silence. Nothing. I checked all the switches and dials. No problem there. Perhaps it was the speaker. I plugged in the

earphones. Still nothing.

I couldn't imagine what was the matter. For the next hour or so, I went over every connection, traced the circuit until I was dizzy. Since I had splurged on all-new parts, I didn't even consider that one of them might be defective. The mystery, so powerful and unfathomable, could obviously have been cleared up in a few minutes by any well-equipped radio repairman. But for me, its unraveling was momentous.

The radio's circuit consisted of two stages. The first stage converted radio frequency waves to electrical impulses of an audible frequency; the second stage served as an amplifier for the electrical impulses coming from the first stage. I hit upon the idea of tapping the earphones in at the end of the first stage. Success! Static, code, voices. This seemed to indicate to me that the trouble lay somewhere in the second stage. On an impulse, however, I tied in a microphone at the very beginning of the second stage. Success again. The second stage worked. I could hear my voice coming from the speaker.

In that very instant, the answer was clear: Both stages worked separately. The trouble had to lie in the coupling between them. My eyes went to a little green-and-silver coil (*the broken connection between subconscious and conscious, the hidden flaw between individual and community*). It had to be that impedance coil. With this certainty, I was quite overcome. I would gladly have broken into a radio store to get another one, but my friend, I found, had a spare. I tied it in, not bothering for the moment to solder it. And a universe poured into my room from the star-filled night. I spun the dial: a ham in Louisiana, in California; shortwave broadcasts from England, Germany, Mexico, Brazil. There was no end to it. I had put out new sensors. Where had been nothing, there was *all of this.*

Ectasy is one of the trickier conditions to write about. But if there is such a thing as being transported, I was transported that night. And I was, as with every true learning experience, forever afterward changed.

Every child, every person can delight in learning. Every educator can share in that delight. The methods are available. The needs for reform are clear. The chief obstacles are simply inertia and low expectations. Actually, a new education is already here, thrusting up in spite of every barrier built against it. Why not help it happen, ■

Push to Talk

(The Twoer Way)

Norm Ross VE3ETJ
Box 26, R.R. 1
Dorchester, Ont., Canada

It all started one bad winter day. I was giving road conditions in our area to another local ham when I reached to push down the transmit switch on the twoer. At the same time another car was coming in the opposite direction. The twoer, being out of arm's reach, made me lean over to transmit. This made the car sway towards the oncoming car. If the driver had not headed for the ditch there would have been a real accident. With my heart in my mouth, this brought me to the conclusion that we needed push to talk.

We did it inexpensively without defacing the Twoer in any way. One evening will do the job, and if you have the assembly manual of the Twoer (HW 30), assembly will be much faster when installing the relay.

Step 1.

The relay which we used was a Potter & Brumfield KHP-17A11-12 volt (4 P.D.T.) The relay is mounted upside down between coil CC and socket V4. To hold the relay down in place, a bracket was made and attached to the mounting screw of the relay. When the bracket is attached, move the wiring out of the way between the coil CC and socket V4 and place it so that the bottom of the bracket is below coil CC and the relay about ¼ inch away from the coil. Drill a 6/32 hole and fasten to the chassis.

Step 2.

Now the wiring begins:

At any time you find the original wiring is too short, replace it keeping all the wires close to the chassis when transferring from wafer switch Z to relay. Start transferring the wiring at pin 12 of the wafer switch Z to pin 9 of the relay.

From Wafer switch Z	To: Relay
12	9
11	5
10	1
9	10
8	6
7	2
5	7
4	3

Pins 6, 3 and 2 are left connected to wafer switch Z.
Pin 11 on the relay is grounded.
Pin 12 on the relay is connected to pin 3 of wafer switch Z.
Pin 8 on the relay is connected to pin 2 on coil CD.
Connect a .01 disc capacitor from pin 6 to pin 11 on relay.

Step 3.

Now that the relay has been wired in, we need a voltage to operate the relay coil. I wired in a half wave power supply and filtered it just enough to close the relay. (If relay does not close, take the tension of the spring until it does close.)

The power supply was made on a four pin terminal strip (PS) using a 50 mfd. at 50 volts condenser and a diode. Place this strip under the screw that holds V3 in place coming from pin 1 of the terminal strip S which has a RFC to pin 5 of V3 (6BS8) filament supply. At this point the relay voltage was taken. Drill a ¼ in. hole near pin 1 of terminal strip S. Connect a wire from pin 1 of S to pin 2 of PS. Connect a jumper from pin 1 to pin 3 of PS. Connect a 50 mfd. 50 volt condenser from pin 1 (neg.) to pin 4 (pos.) of PS.

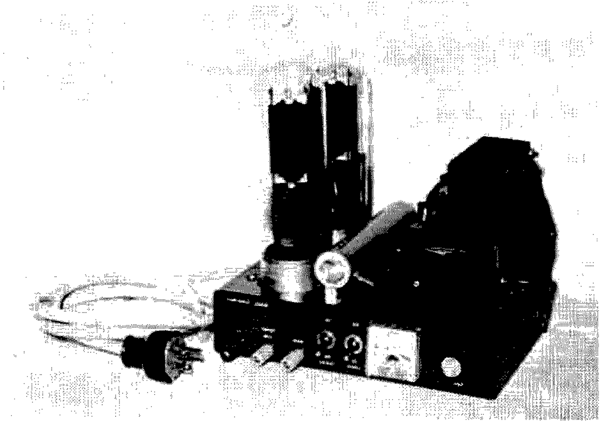
Connect a wire from pin 4 of PS to pin 13 of the relay.

Step 4.

All that's left is the microphone connection. Replace the mic. connector 432-3 with any 4 pin female connector. Pins 3-4 of the connector are grounded. Pin 2 goes to RFC coming from pin 1 of VI. Pin 1 goes to pin 14 of relay. Connect jumper from pin 14 of relay to pin 5 of wafer switch Z. For the mic. cord we used an Armaco TFCC and the mic. was a ceramic with push button. The old transmit switch will still work as if nothing had been changed, except we don't have to reach down and fumble with the switch. We have a tener with the same modification, now all THREE of us are doing fine! . . . VE3ETJ

Variable dc Load

D. P. Bryan, W2AJW
4 Crescent Drive
Applachin, New York



Quite often electronic construction articles go to great lengths to describe the functions of components, their minimum or maximum allowable values and how the circuit works, but end up skimping on explanations about the power supply section. More likely than not they merely state the required voltages and currents and leave the power supply design up to the builder.

Most electronic manuals furnish data and design details for power supplies. If you are the type of builder who can afford to go and buy all new components to build exactly to the handbook design then you won't have any trouble. However, in this world of surplus and used TV set power supply components, most builders turn to the junk box first for the power supply parts.

Since it is rare to find the exact components, even in the best stocked junk box, the builder usually ends up with a power supply constructed with components quite a bit different than those specified. We know it will work but *how well* will it work? Naturally, attaching it to the piece of gear it will power will be the "acid test," but why compound problems? Why try to test and debug a new piece of gear with a power supply that may be bugged because of inadequate regulation or filtering. A power supply defect can really hide itself and show up as a bug on the gear being tested—like distortion in a linear amplifier because of poor power supply regulation.

Why not test the power supply "off-line" before using it?

Here's how.

If you have ten or twenty assorted high wattage resistors or a 200 watt variable resistor in your junk box and don't mind the inconvenience of dropping power to change the resistor or vary the tap then do so as indicated in **Fig. 1A.**

If you have a couple of old transmitting tubes with high plate dissipation, a filament transformer to match, a couple of low wattage variable resistors (one being a potentiometer), a dc milliameter, a small power transformer for bias, and want complete flexibility and ease of control, then do as indicated in **Fig. 1B.**

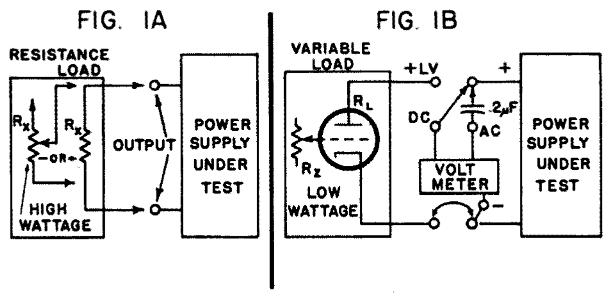


Fig. 1. A high wattage fixed or variable resistance load can be replaced with a triode vacuum tube controlled by a low-wattage variable grid resistance.

Since I had a couple of old VT-4-C's (211's) with big graphite plates rated at 100 watts dissipation each in the junk box, I chose procedure 1B. This decision was also prompted after burning my fingers a couple of times changing hot resistors as in procedure 1A. Actually, any tubes will work. The decision as to type should be made based on plate dissapation rating. Pick the tubes with the highest ratings. The maximum loading and power consumption by the unit will be determined by the plate dissipation of the tubes used.

How it works

Fig. 2 shows the diagram of the variable load. The load consists of tube power dissipators and a bias power supply with a means (R2) of controlling the bias and

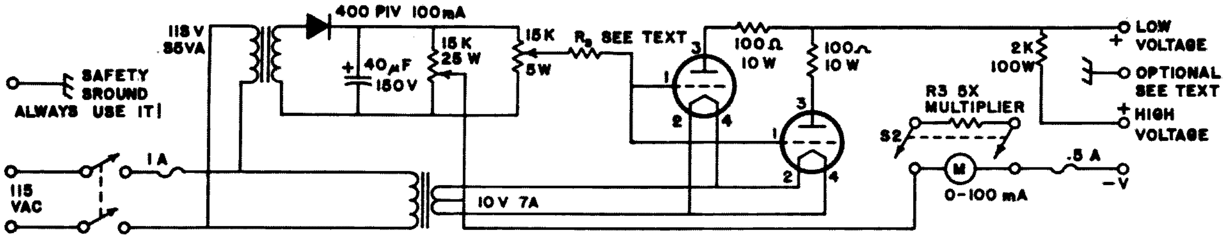

Fig. 2. The practical circuit. Grid and anode re-sistors improve circuit stability.

therefore current drawn by the tubes. A dc milliammeter (M1) is inserted in the cathodes of the tubes to measure the current through the load. The meter has a basic 0-100 dc mA range that is extended to 0-500 mA by switching (S2) a five times shunt (R3) across it to test heavy duty power supplies. A voltmeter is connected between the input terminals (−V) and (+LV or +HV) to simultaneously measure power supply output voltage or ripple and current. The 100 ohm 10 watt resistors in the plate circuits of the tubes are necessary to assure stable tube operation. The resistor in the plate lead from the +HV is necessary if higher than rated voltages will be tested.

As stated earlier the current drawn by the tubes is controlled by R2 which varies the bias on the tubes. Basically, a tube is cutoff (drawing no current), when the grid is more negative than the cathode. A tube is conducting (drawing current), when the grid is more positive or moved closer to the cathode potential. The degree of conduction or current draw depends on the bias setting between these two extremes. Hence the principle of operation of the variable load unit.

Adjustment

The cut-off bias condition of the tubes is set by:

1. Set slider on R1 to mid range.
2. Set potentiometer arm R2 to full minus end. The potentiometer should be wired so this condition exists when the arm is rotated fully counter clock wise.
3. Connect the unit to an external power supply. This supply should be one with a highest output range available which can be used with the type of tubes used in the variable load.
4. Turn on the variable load.
5. Turn on the test power supply.
6. If the milliammeter M1 shows any indication, turn all power off and move the slider on R1 towards the plus end of the resistor. If the meter does not move go to step 7. Turn on power, steps 4 and 5, and again check the milliammeter for a reading. Repeat this step until R1 slider is set at a point that current just stops flowing.
7. If the milliammeter M1 does not show any indication turn all power off and move slider of R1 slightly towards the minus end of the resistor. Turn power on, steps 4 and 5, and again check the milliammeter reading. Repeat this step until R1 slider is set at the point where current starts flowing, then back off R1 slider to the point where current just stops flowing.
8. Steps 6 and 7 will set the bias point of the variable load so that its maximum range of loading can be utilized.
9. Insert a milliammeter between the arm of R2 and the grids of the tubes and measure the current drawn when R2 is set for full conduction. If the value is higher than that allowable for the 5 watt rating of R2 insert a resistor at RS to bring the current back down. The slider of R1 should not be set any closer than 15% of its total value to the minus end of the resistor. This will limit the tube grid current when R2 is set for maximum conduction at the plus end and help prevent R2 burn out.

Grounding

Notice in **Fig. 2** that the only thing grounded to the chassis is the ground conductor of the three wire ac line cord. This will allow testing of minus as well as plus power supplies. The three wire line cord with ground is essential in this application in the event of a short circuit to the chassis. For that matter it is recommended that all electrical equipment be equipped with three conductor power cords. If grounded power cords are not used in your shack then the variable load chassis and the power supply chassis should be bonded together before running any tests.

Operation

In the following two examples the test

set up should be as shown in **Fig. 1B.** The voltmeter should be connected for either ac or dc operation depending on whether measurement of regulation or ripple is the object of the test. Graph paper should be used to plot the progress or results of the test. (It's a lot easier to "see" what a series of numbers represent when they are plotted on a graph.) The graph should be set up with voltage increments on the vertical axis and current on the horizontal axis. The steps or size of the increments will generally depend on the two extremes of the measurement. Try to keep the graph spread out for accuracy.

Once the equipment is set up power is turned on and the load control R2 is turned clockwise until the amount of current representing the first current increment is indicated on the milliammeter. The voltmeter is then read and the indicated voltage is logged as the first spot on the graph. R2 is then advanced to the next current increment and the voltage is again read and logged. This process is continued through the last current increment at which time a line should be drawn connecting each spot on the graph paper completing that part of the test. At this point a component can be changed and the whole sequence runs again to see if an improvement was realized.

These two examples will give you an idea of how it works:

1. Regulation—The graphs in **Fig. 3** were made by testing a power supply using a transformer with an unknown current rating. Two unmarked chokes, L1 and L2, were tied in the power supply to see which offered the best regulation. A dc voltmeter was connected across the power supply output to measure the voltage under the different current settings.

Examination of graphs 3B and 3C shows that the choke used in 3B has 16% better regulation (ac ripple was the same in both cases). The addition of a 10 mfd input filter capacitor and going to a 35 mfd output filter capacitor, **Fig. 3D**, actually made the regulation worse, to 33%, and had little effect on the ripple.

The circuit selected for the power supply was that of **Fig. 3B.**

2. Ripple—The graphs in **Fig. 4** were made to determine the proper value of filter capacitor required to maintain a ripple constant of less than 3%. In this case an ac voltmeter, with a suitable blocking capacitor, is connected across the power supply output to measure the ac component.

FIG. 3

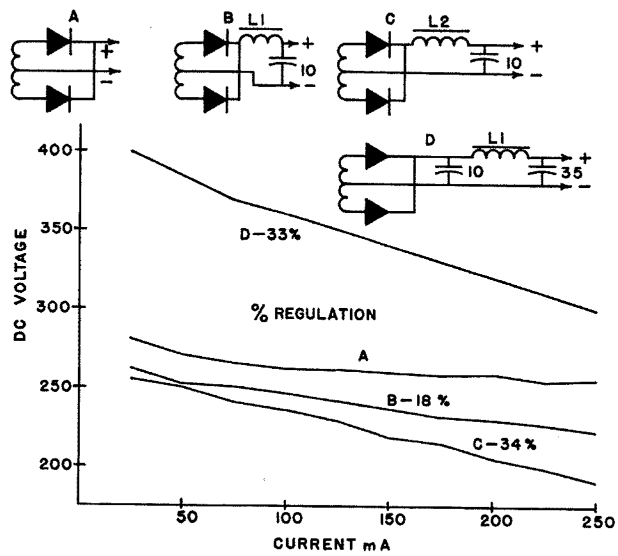

Fig. 3. Test results, obtained quickly and easily, illustrate power supply performance under load.

It can be seen that graph 4B with the 35 mfd filter capacity gives 11% less ripple than the circuit using only 10 mfd of filtering. Circuit 4B also gives slightly better regulation.

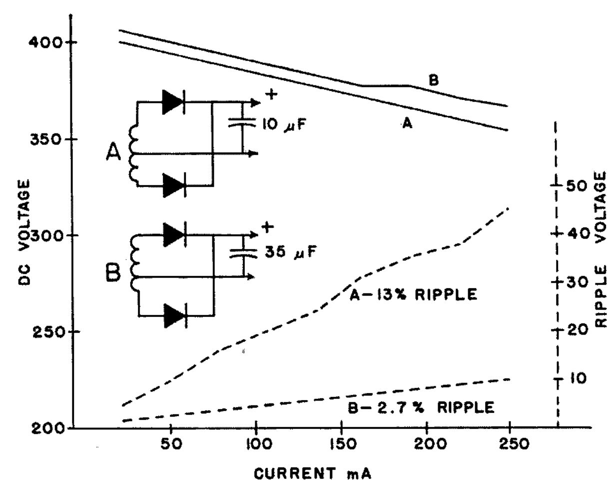

Fig. 4. As power supply load increases, voltage drops together with an increase in ripple.
Variable dc load-Controls left to right: minus voltage, plus low voltage, plus high voltage, ac power/off, meter X5 multiplier switch, meter, load control. The large resistor on the top center of the chassis is in series with the plus high voltage terminal and allows testing of supplies with output capacities greater than the tubes can handle.

These are but two examples of what you can do with a "Variable dc Load." As with anything else, its total effectiveness will be up to the ingenuity and inventiveness of the user.

Single Side SWR Bridge

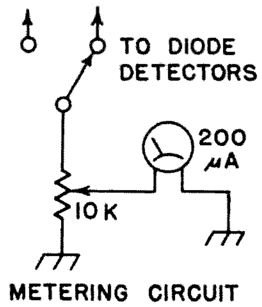

Fig. 1. Metering circuit for the Single-sided SWR bridge.

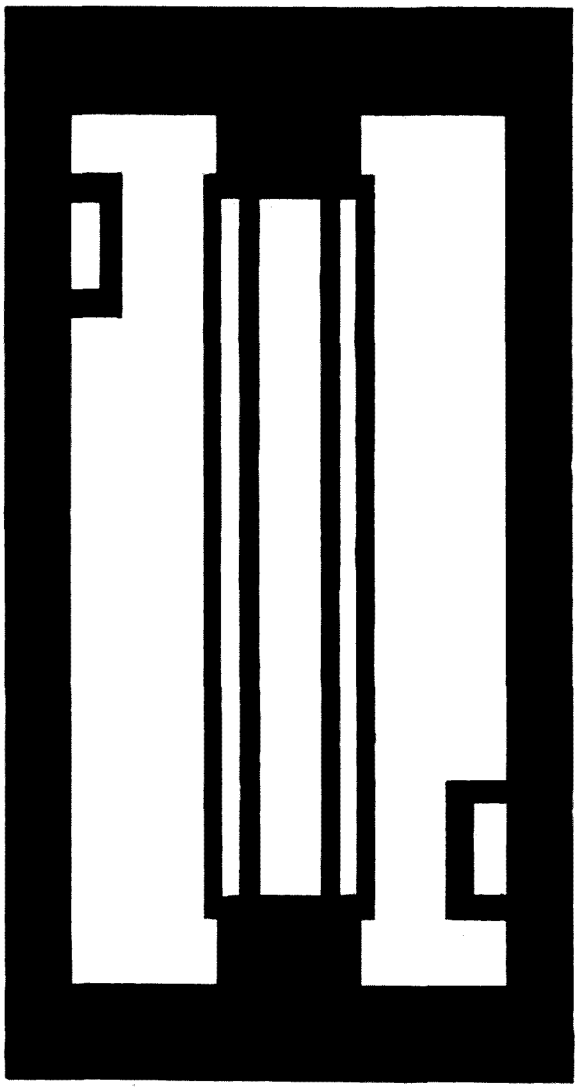
Ed Lawrence WA5SWD
615 *Sherwood*
Richardson, Texas 75080

After reading the articles in 73 on SWR bridges that led up to the double-sided board pick-up,* I decided to try my hand at building one, but on single side board.



Several of these boards have been etched and units assembled, and all have been satisfactory. I have used mine, with a 200 micro-amp meter, from a kw on the low bands up to a "Twoer," with no problems with sensitivity.

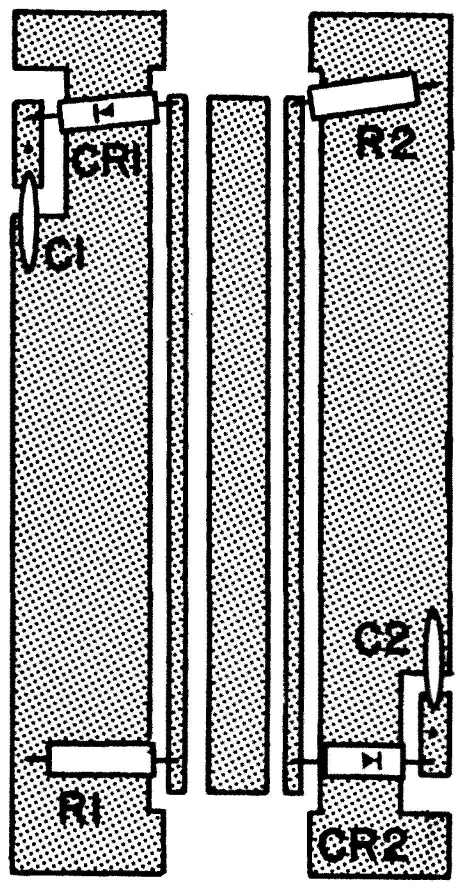


Fig. 2. Layout for the printed circuit board.

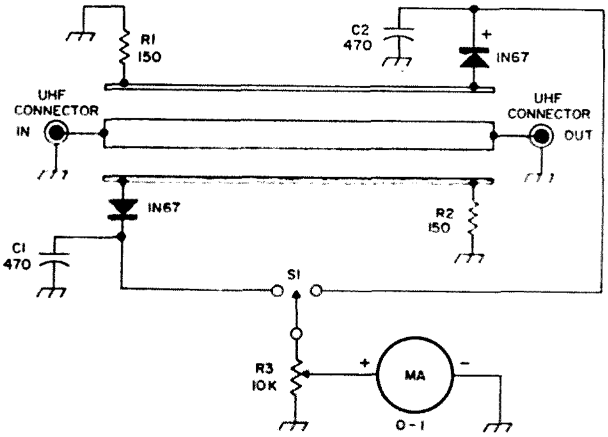
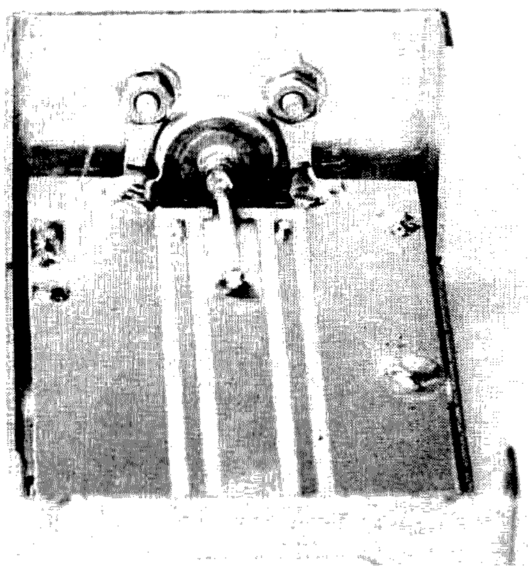


Schematic diagram of SWR bridge.

Since Bud Miniboxes are commonly available, I scaled this board to fit into the Bud Minibox CU 2102A or CU 3002A. If you want to include the metering in the same package, the CU 2103A or CU 3003A should be used to give more room.



If you use the CU 2102A, center the coax connectors on the ends. If the CU 2103A, mount the connectors .8 inches from the open end. I used solder lugs bent at right angles to mount the P. C. Board to the chassis. The photograph shows the mounting much better than 10,000 words.

The meter sensitivity control circuit shown has a wider control range than the one shown in the *ARRL Handbook*, since the pot shunts the meter at low settings. This action could be accentuated by putting a fixed resistance in series with the meter movement, at the expense of sensitivity.

100 KHz Marker Generator

W. W. Davey W7CJB
329 *East Kent*
Missoula, Montana 59801

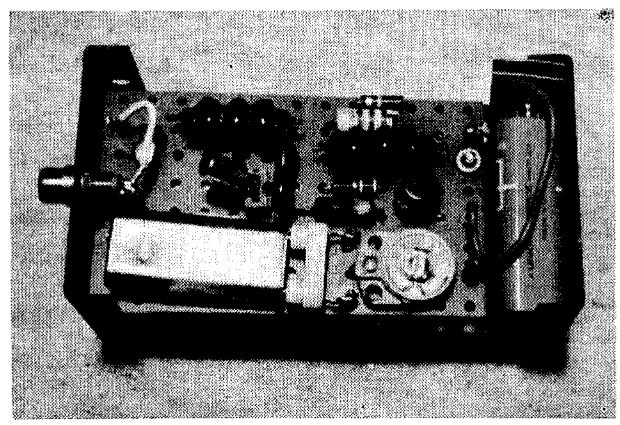
This useful piece of equipment generates usable harmonics from 100 kHz to 225 MHz. It is completely self contained and portable which makes it convenient not only to use in the ham shack, but also in the mobile unit or at a field day location. Its use lies mainly in accurately spotting band edges and 100 kHz calibration points throughout the ham bands.

Most modern day home receivers are equipped with calibrators, but these calibrators are of little use when needed to spot frequencies on VHF and UHF converters or portable equipment.

The generator is constructed in a 2¼ x 4¼ x 1½ inch handi-box. The parts are mounted on a vector board, and the entire unit is powered by one #216 nine volt battery or its equivalent.

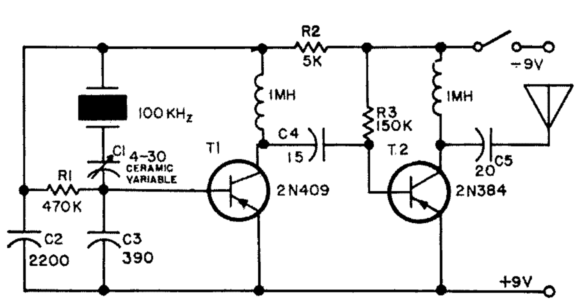
Hints on construction First obtain some vector board. The piece I used was cut from the board supplied in a "GE experimenters aid hobbyist kit." The board must be cut to size before construction and will measure 3½ x 2 inches. This will allow room for the 9 volt battery in the end of the handi-box. Make sure the newly cut vector board will fit inside the handi-box before you start mounting parts. It might save a lot of trimming at a later date.

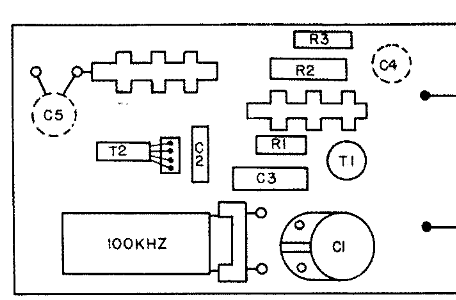
The parts layout is not critical. Components may be arranged as shown in the photo or in any other arrangement suitable to the components you may be using. I used sockets for the transistors, as I wanted to be able to experiment to see which transistors from my junk box would give the most output in the VHF and UHF bands. I ended up using the 2N404 for the oscillator and a 2N384 in the multiplier



stage. I also found that Japanese 2SA83 transistors which had been removed from the *if* stages of a junked transistor radio, would work equally well in both sockets.

All components are mounted on the top of the Vector board with the exception of C4 and C5. For the most part, wiring can be completed with existing leads on components. The push-in terminals furnished with the GE experimenters kit were used for the battery connections, antenna connection and for mounting the crystal socket. The circuit board can be mounted to the handi-box with three 11/16 inch bushings. This leaves room for a slide switch to be mounted on the cover of the handi-box. Two of these bushings were purposely placed at the end of the board to form a sort of socket to hold the 9 Volt battery. The antenna output connector which is mounted on the handi-box is a switchcraft #3501FP phono jack. A small hole may be drilled in





the bottom of the handi-box through which a screwdriver may be inserted for adjusting CI. For extreme accuracy CI is adjusted to zero beat with WWV.

A 36 inch piece of insulated wire soldered into a phono plug may be inserted into the phono jack and used as a test antenna. The intensity of the markers may be varied by moving this test antenna near your receiver antenna lead-in. If you are using a coax lead-in you can couple by drilling a small hole in your coax relay so that the test antenna can be inserted near the relay armature. You will find that most SWR meters provide an easy method of coupling to the center conductor of the coax. As a last resort you can always couple to the receiver or converter antenna coil.

I have made very good use of this gadget to spot frequencies in the 144 and 220 MHz bands. It was well worth the time and effort it took to build it.

...W7CJB

OA2 PECULIARITY

In the process of putting together a small regulated power supply I found myself in need of a convenient stand-off. Unhappily I picked pin 3 of an OA2 gas regulator tube. It seemed like a reasonable choice, but I can assure you that this is not the thing to do.

If you look closely at the tube you will see that the connections from pins 3 and 6 go through the glass envelope and extend about ¼ inch into the tube. They are not connected to any part of the tube. The Handbook shows the pins to be internally connected.

What happens is this: the short pins act like anodes. If you put 500 volts on one of the pins the tube will fire and draw current. In my case there was nothing to limit the current and the tube really went wild!

Conclusion: do not use these pins as stand-offs.

Robert Bailey K3AQH
Philadelphia, Pennsylvania

One Technique to Avoid that Routine QSO

Maurice Hindin, W6EUV
10471 LeConte Avenue
Los Angeles, California 90024

From time to time amateur radio magazines have all carried editorials and correspondence from their readers directed to the problem of the boring routine QSO ("de W2NSD/1" 73 Jan. 1969; "It Seems to Us" QST Feb. 1969). It has even been suggested that one of the reasons why amateurs often lose interest in their hobby is the uniformity and sameness that most QSO's take. After exchanging a thousand or more reports which simply contain the routine information giving the signal report, QTH, name, power and type of equipment used, followed by the usual "QRU, 73 cul" it is true that the routine QSO can become a dull affair.

Although there has been a great deal written about boring QSO's, very little has been written about what an individual ham can do to improve the situation.

The reason why so many QSO's degenerate into a stereotyped routine exchange of information is in the writer's opinion, the result of several things: First, the operator doesn't know what to talk about and second, he forgets that he is talking to a human being and not just a piece of electronic equipment. Third, the operator is really suffering from mike (or key) fright. As soon as the operator recognizes these facts, something positive can be done to make the average QSO an interesting experience. Many years ago, the writer became aware of his conversational ineptitude at the mike and devised a simple technique which produced excellent results. It may probably have been instrumental in making amateur radio for him a lifetime hobby.

The problem in the first instance is what to talk about after you have completed the routine information. To avoid not knowing what else to say, the writer wrote a series of questions about things that were of interest to him. They were simply things that he would like to ask any new friend that he had just met. Some words of caution are in order, however. *First,* simply asking a lot of questions will not make the QSO necessarily an interesting experience. It is the willingness to share your answers also to the questions you ask with the other fellow that makes for an interesting conversation. *Secondly,* do not ask a question of the other fellow that you would not want to answer yourself if he asks the same question of you. This, however, is really no different than your conduct would be in any social contact with another person. *Thirdly,* the question should not embarrass an ordinary person whose particular beliefs you do not know. One good test is would the information that the question calls for embarrass you if it were asked of you. *Fourthly,* it is not too wise generally to ask questions which you know will invite a controversial answer ("It Seems to Us" QST Feb. 1969). This also is a matter of simple good manners. After all, a QSO should be something that is pleasant for everyone and there are vast areas of subject matter that can be discussed and explored without getting involved with controversial subjects.

The specifics of a program the writer used to eliminate dullness in the QSO require simply listing a series of questions about things of interest to you. Then the moment your mind turns blank as to what to say next or the QSO starts to dry up, simply look at the list and start it up again.

After using the list for a few months, it became almost second nature to engage in friendly informative QSO's, each of which were different from the other and many of which opened the doors for long-term friendships.

As a practical matter, I found that if I volunteered some information first and followed that with an inquiry on the same subject, it would invariably open the door to more discussions and before long a genuine feeling of knowing the other fellow was developed. If you visualize that you are talking to someone sitting next to you as if he were in your own room and not going through a routine testing procedure, the routine stereotype type of QSO which does get tiresome can be avoided. Listed below are the twenty questions which have provided the framework for many pleasant, interesting and diversified QSO's. As you can see, there is nothing unique about the questions. You can easily prepare another list of questions for yourself. The questions are simply guidelines to keep

the QSO going so you will never find yourself in the position of not knowing what to say next. If the questions listed below sound interesting to you, simply use them. If other subjects of conversation come to mind that you would prefer to discuss, then of course, use them. The point of the whole idea is that if you make up a list of questions or subjects and have it on the operating table, you can with a minimum of effort change a boring routine QSO into an interesting conversation with a newly made friend.

My list contained the following subject matter:

1. (I am a machinist.) What kind of work do you do? (If he says he is in school, then ask what school grade, and what does he plan to do when finished.) (If he says he is in college, ask him where it is, what he is taking. If you have been to college, tell him about it.)

2. How long have you been doing that work? (I've been a machinist for 17 years.)

3. (I've been on the air since 1935.) How long have you been on the air?

4. What other bands do you operate? (I operate on 15 and 2.)

5. Do you ever operate any other mode? (I operate part time on CW and part on sideband.)

6. Have you ever visited here in Podunk? (Your town.) I've never been in Lower Culicutt (His town). The nearest I've been to Lower Culicutt was in Upper Culicutt (or where is Lower Culicutt?).

7. (I have been a stamp collector for years.) Do you enjoy any other hobbies?

8. (I wish I had more time to operate. I only get on weekends.) How about you?

9. (I've got two children.) Do you have any children?

10. (My kids are 10 and 12 years old. A boy and a girl.) How old are your kids?

11. Are you interested in DX work? (I am. I've got 110 countries confirmed.) How about you?

12. Have you heard or worked any Dx lately? I've just worked UAØYE in Zone 23 after trying for years.

13. What kind of an antenna do you use? (I use a cubical quad.)

14. (I have (or have not) used the type of beam you have.) Have you ever compared it with any other type?

15. (I've been studying for an extra class ticket for a month now.) Have you started working for an extra class ticket?

16. Do you like to build your own equipment? (I do (or do not) like to build my own equipment.)

17. If he says he does build his own equipment, then ask what he has built, and what will be his next project? Tell him what you have built, and what your next project will be.

18. Are you active on any nets? (I check in regularly on the XYZ net.)

19. Are you ever bothered with TVI? (I cleaned mine up or I still have trouble.)

20. If he is bothered with TVI, tell him how you cleaned up yours.

The preparation of a list of questions or subjects has been a practical solution to the problem for the writer. As a matter of fact, once you have tried the Q and A method, you will find there is generally so much to talk about that it is often necessary to terminate a QSO long before all of the subjects are even mentioned.

While the foregoing idea may not be the only or ultimate solution to the problem, it is at least a step forward toward doing something to avoid those dull routine QSO's. It is perhaps an application of the old saying that "It is better to light one candle than to curse the darkness." ...W6EUV

Minimum Cost Semiconductor Silicon Survey

Conrad C. Zaranski
P.O. Box 64
CheekTowaga, New York, 14225

Purpose:

Obtain the cheapest silicon transistors from any major manufacturer. Explore possible applications. Develop useable characterization of devices by actual laboratory measurement.

Background Information:

A manufacturer begins with several basic chips of differing geometry, which are then electrically graded into several broad device families. Some will become hi-reliability mil-spec units, hermetic commercial equivalents, house numbered custom spec units, and recently, consumer grade economy units. The economy transistor did not attain respectability until the advent of silicon Planar* technology control which produced high yield uniform quality devices. The residual product remaining after several grading steps still possessed well-defined characteristics and was registered. This gave the familiar 2N . . . designation to these economy units.

The transistors selected are manufactured by Fairchild and are packaged in either the TO-105 or TO-106 case style (ceramic/epoxy) similar to the TO-5 and TO-18 units. Price shown: 100 pc. lots - 1 November 1968. The study graphically illustrates key parameters which influence cost, and inherent parameters which remain after grading.

To insure reasonable data accuracy, minimum sample (any type) was 100 devices, typical size 300 devices, maximum 100, total 3,300. The devices were procured over an eight-month period (different manufacturing date, codes,) to typify parameter spreads within lot sample sizes most hams would use: Sample distributor sales tend to have more non-uniform parameter distribution than large, bulk O. E. M. sales since most bulk O. E. M. users specify some parameter distribution (not more than 5% of the lot of X thousand shall have parameter Y lower than......or higher than......). This specification is usually derived from the peculiar circuit designs, employed, an uncontrolled family characteristic, or critical limit device requirement. This may produce some unnatural distribution of a key parameter after these sales are completed.

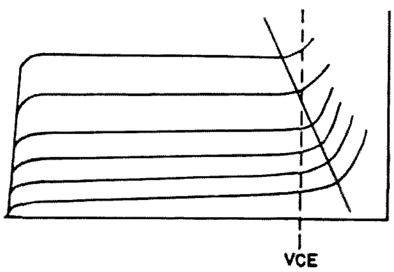
These abbreviations are used in the article

C_{CB} — Collector to Base Capacitance
V_{CBO} — Collector to Base Voltage
V_{CEO} — Collector to Emitter Voltage
V_{EBO} — Emitter to Base Voltage
N_F — Noise Figure
P_G — Power Gain
F_t — Gain Band width Product measured at 100 MHZ
Example F_t = 600 100 MHZ x 6.0
V_{CE} SAT. = Collector Saturation Voltage
H_{FE} = D C Beta
H_{fe} = AC Beta
T_s = Storage Time
T_d = Delay Time
T_R = Rise Time
T_f = Fall Time
Ton = Turn on Time
Toff = Turn off Time



VCE MEASUREMENT

F_t Measurements are made at 100 MHZ. This single measurement will show whether a particular device is capable of high-frequency operation. Specification for Collector to Base Capacitance was used to determine relative merit among devices of similar F_t. Several devices of each type were subjected a 100 MHZ noise test. Devices selected were taken from three F_t groups (low, median, and high F_t). Results were inconclusive. Leakage current was not measured—maximum is 50 Nanoamperes (per spec.) for all types. Beta linearity was measured at several frequencies and collector currents. Condensed data sheet Values are given, a distribution curve is drawn, and then our conclusions. Some devices just do not measure up to the data sheet.

2N5126 – NPNSi RF Amp.

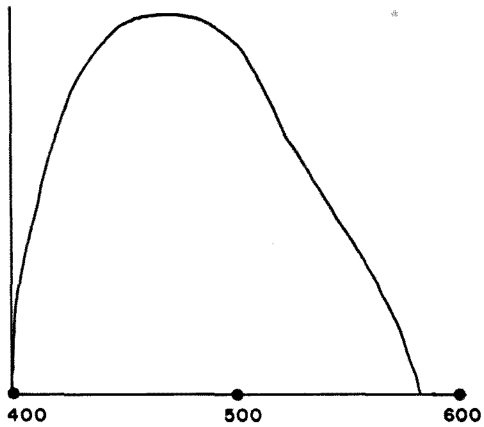
NF = 5.5db. Typical @ 100 MHZ.

Use: AGC Controlled *if* and *rf* stages of



2N5126 FT DIST

to 100 MHz. AGC Gain reduction vs. current exhibits considerable variation. AGC current and non-AGC'd gain from device to device does *not* track well. This can be helpful to obtain a progressive overload capability to allow wide dynamic range in an *if* amplifier. The 20^{+Y}CE is more than adequate. Noise performance ran slightly more than 5.5 db.@100 MHz. F_t was much lower than anticipated, no unit had F_t greater than 600. A rough approximation of AGC Control current can be obtained, by watching β Compression at higher currents on a curve tracer. The device is useful from 1 to 4 mA., ignoring AGC effect, but there are better types available. High-frequency performance above 100 MHz is erratic due to corner noise and F_t distribution

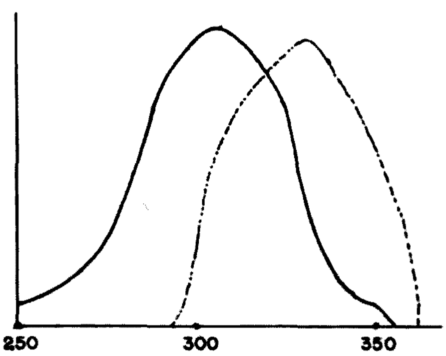
T_{off} 80 ns. Typical I_b 30 mA

When swept β measurements were made, units were found to have good Beta at very low currents. Exceptionally good wide range low to high current and linearity. F_t very narrow spread. 2n5123 has higher and F_t curve. It is a nice wide current general Purpose device which reminds me of a 2N2219 but probably not the same chip. I have used it as a current driver/buffer for oscillator amplifiers, tripler drive, large signal *rf* oscillator, audio drivers, and small signal *rf* amps. At 13 cents for either package, this is quite a device.

If higher V_{CBO} and V_{CEO} are required it is



2N5128–2N5129 FT

suggested the following similar devices be utilized.

2N3641	V_{CBO} 60 Volts	28 Cents
	V_{CEO} 30 Volts	
2N3642	V_{CBO} 60 Volts	33 Cents
	V_{CEO} 45 Volts	
2N3643	V_{CBO} 60 Volts	38 Cents
	V_{CEO} 30 Volts	

NOTE: These are not devices for operation at VHF frequencies at high power levels—efficiency drops.

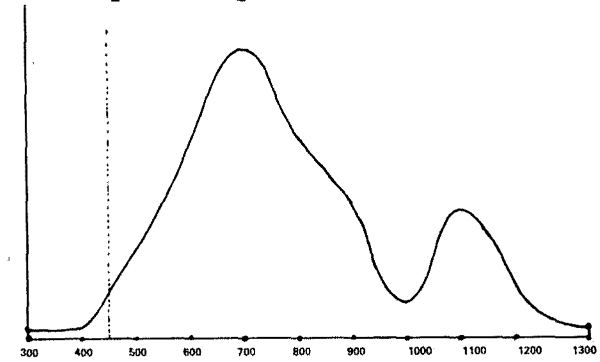
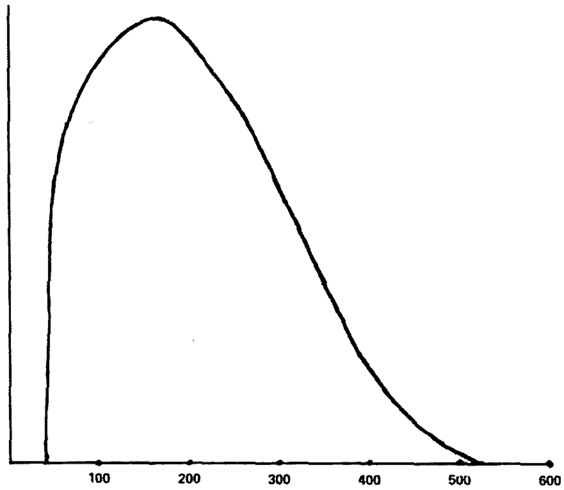
F_t = 450 MIN 900 Typical

Most of the transistors were below typical B, typical *rf* Performance, some were out of spec-LO and LO F_t performed like LO 2N918. None of typical specs are met by the majority of devices, though most of the devices perform quite well around 2 meters.



2N5130 FT

Suggested grading in 144 MHz *rf* AMP Stage Biased At 6 to 8 mA. It only costs 11 cents. Good from 100 kHz to ? High Freq. corner unpredictable without F_T Measurement. The 2N3563 costs 30 cents. It is a little better (F_TMIN 600) noise performance similar, 200 MHZ power gain guaranteed MIN 14 db. Hundreds of 2N5130 transistors have been purchased by local VHF FM'ers. They use them interchangeably with 2N918's for local oscillator/multiplier chains, if strips, trigger circuits and mixers. Everyone has been well-satisfied. Since this device was being used extensively the evaluation of this type was reopened in October, 1968 and several hundred additional devices were measured. New test groups were included, and all transistors were tested for V_{CE} Breakdown. High, low and medium V_{CE} units were grouped and were checked

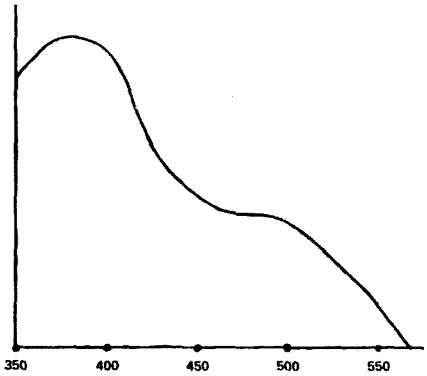


2N5131 1 kHz B Distribution

for Band F_T correlation. Low limit V_{CE} units were found to have low limit B and F_T. High and medium V_{CE} units had random distributions. These low limit units were considered "rejects." Upon removal of these items from the sample the lot was acceptable.

2N5131 — NPN General Purpose
H_{FE} = 30-500 @ 10 mA. 1 Volt
F_t = 100 Minimum I_c = 10 mA. @ 15 Volts
BV_{CBO} = 20 Minimum
V_{CEO} = 15 Minimum
C_{CB} = 6 pF Maximum
V_{CE} Sat = 1 Volt Max
1 kHz hfe = 25 MIN 600 MAX 10 Volts Ic = 10 mA.

A high B unit at 10 mA. Beta falls off at low currents. V_{CE} sat not too good, measurements to high side of spec. One unit considered a "reject" for low F_t. All other units well above minimum F_t Spec. I prefer other devices for specific applications, so have not found any use for this device. Cost: 11 cents.



2N5131 FT Distribution

2N 5132 — NPN AM/FM AMP Graded from 2N3693, 2N3694
VC_{BO} = 20 Volts Minimum
VC_{EO} = 20 Volts Minimum
Pulse H_{FE} 30-400 I_c = 10 mA @ 10 Volts
P_G = 32 db Typical @ 10.7 MHz I_c = 7 mA @ 10 Volts

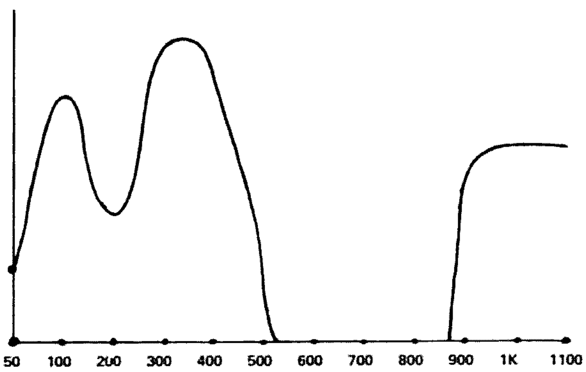
2N5132 FT Distribution

P_G = 55 db Typical @ 455 kHz I_c = 3 mA @ 10 Volts
F_t = MIN 200 Typical 350 I_c = 10 mA @ 15 Volts
V_{CE} sat. = 2.0 Volts
C_{CB} = 3.5 pF max.

This unit tests identically to the 2N3693-94 except 2N3693 and 2N3694 are 45 volt units (minimum). Noise performance was *not* tested. V_{CE} was not very good. The 2N5132 cost 11 cents. 2N3693-4 are 30 cents. Rated better than data sheet limits.

2N5133 NPN Hi-Gain Low Noise
(*Similar to SE*4001, 4002, 4010)
NF = 1.5 db. Typical @ 1 kHz
H_{FE} = 60 Min 220 Typical 1,000 Max @ 1 mA 5 Volts
H_{FE} = 50 Typical @ 50 mA.
V_{CEO} = 18 Volts MIN
V_{CBO} = 20 Volts MIN
V_{CE} Sat = 0.4 Volts Max
h_{fe} = 50 Min 1100 Max @ 1 mA 5 Volts

The curve tells the story. Something is missing. Some current fall off at low currents. Reasonable NF for most work between 1 kHz and 5 MHz in preference to most other NPN Bipolars. It has nice V_{CE} sat compared to other types. It costs 11 cents. It is good from 20 mA to 3 to 4 mA range. Difficulties were encountered with some units used in an audio circuit due to oscillations which occurred at about a 10 MHz rate. Some units are very noisy. Check to insure this is really noise, not spurious oscillation. Several hundred units were checked.



2N5133 B Distribution

2N5134 NPN Hi Speed Saturated Switch
(*Similar to 2N*4274, 2*N*4275, 2*N*3011, 2*N*2369)
V_{CE} Sat .25 @ 10 mA MAX Ib = 1 mA
.20 @ 10 mA Ib = 3.3 mA

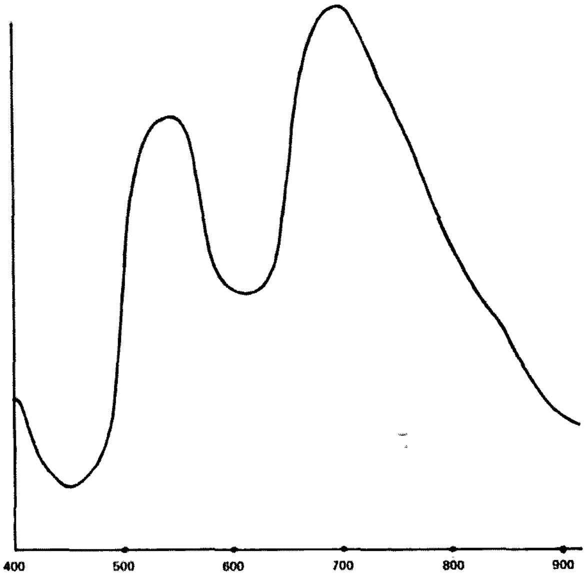
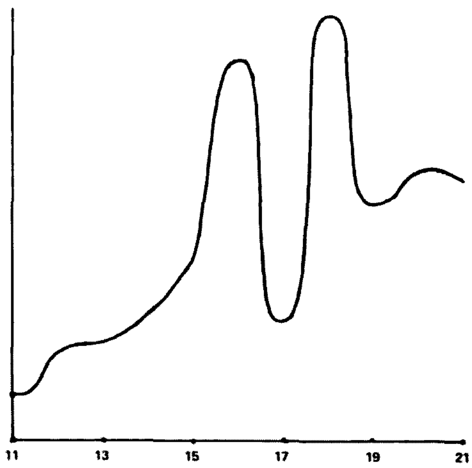
V_{CEO} = 10 Volts MIN (10 mA Pulse)
Ton – 8 ns Typical 18 MAX
Toff 7 ns Typical 18 MAX
F_t MIN = 250 MHz @ 10 mA
F_t Typical = 575 MHz

Beta correlates with F_t. Good V_{CE} Sat. Useable at currents under 1 mA. Nice *rf* amp at 5-20 mA. Not too bad NF either, to 200 MHz. Beta linear. It costs 13 cents.



2N5134 FT



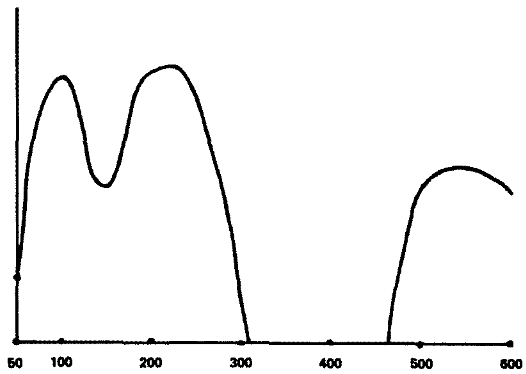
2N5134 VCE Distribution

The 4274 and 4275 Transistors cost 29 and 30 cents. I use it in *rf* Oscillators, pulse inverters, 4 V logic circuits, 6 V lamp drivers, xtal controlled multi's. Good value. May be matched with 2N5140 as complementary pair.

2N5135—NPN High Gain
to —105 Package
Gradeout of 2N3566 similar to SE6001, 6002
Pulsed h_{FE} Min 50 Typical 400
Max 600 @ 10 mA 10 Volts
Pulsed h_{FE} Min 15 Typical 325
I_c = 2 mA @ 10 Volts
V_{CEO} = 25 Volt MIN
V_{CES} = 30 Volt MIN
V_{CBO} = 30 Volt MIN
V_{CE} Sat Typical @ 0.9 Volts
MAX 1.0 Volts @ 100 mA
Ib = 10 mA

Summary:

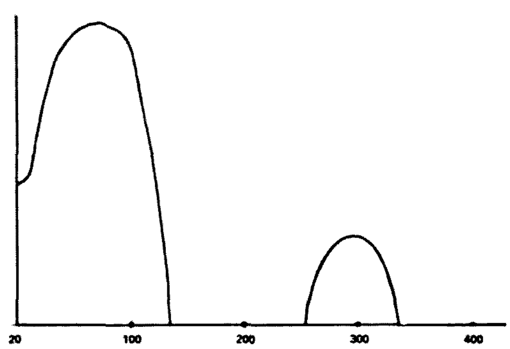
The curve tells the story. Typical value is missing. Transistor is good for audio drivers general purposes to about 10 MHz. Device selection can be made by one measurement. It costs 14 cents. The 2N3566 is 24 cents. V Sat not too good for switching applications. Device noise level in most units was lower than the 2N5133. It has much higher breakdown voltage. Good value; have hundreds measured.



2N5135 B Distribution

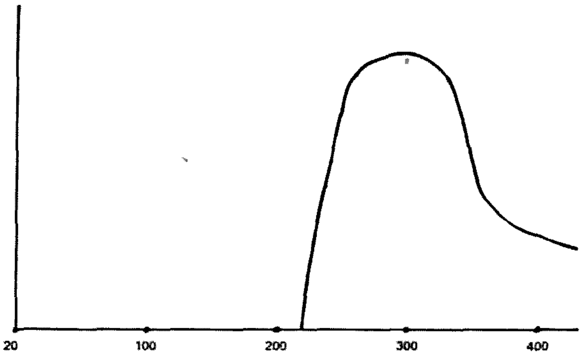
2N5136 – 2N5137 NPN General Purpose Amp.
(*Graded from 2N3567, 2N3568, 2N3569.*)
V_{CBO} = 30 Volts MIN
V_{CEO} = 20 Volts MIN
Pulse H_{FE} Minimum 20 Typical 100 Maximum 400 @ 150 mA 1 Volt
C_{CB} = 16 pf Typical 35 pF Maximum
V_{CE} Sat. = 0.25 Volt Max. @ 150 mA.

The Curve tells part of a story. The swept beta collector family curves showed a pronounced Beta peak at 1 to 3 Volts V_{CE}. Beta was not linear. The curve looked similar to 2N1613 series chips. Pulsed Beta measurements per spec are made at the point where Beta has theo peak. On some units this may be more than three times Beta at normal load line points. Switching



2N5136 B Distribution

characteristics are reasonable. C_{CB} is considered to be very high which makes this device unsuitable for *rf* applications. This is not a very high frequency device. Unit Cost is 11 cents. The 2N5136 is packaged in the TO-105 case, 2N5137 in the TO-106 case. The 2N5137 had higher Beta. Not Recommended.



2N5137 B Distribution

This concludes the NPN Portion of the Survey. Transistors I was most impressed with were the 2N5128, 2N5129 Due to extremely good linearity over a wide current range, and nice switching characteristics. The 2N5134 I use as substitute for 2N706, 2N2369, 2N3011, because the epoxy case is much nicer than a unit with a "hot" case (Collector connected to case) (Case does not radiate switching noise).

The 2N5126 is handy for gain controlled applications in the *if* region; *if* devices are selected for this characteristic.

The 2N5130 is useful for *rf* Amps, although it did not meet expectations.

The 2N5135, and 2N5133 are nice for low frequency work if it is measured, and the 2N5136, 2N5137, 2N5132, 2N5131, 2N-5127 find less application.

Most applications do not need any higher V_{CBO} and V_{CEO} than the above devices in each category provide. For most ham work I prefer discrete components to LIC's due to the poor noise performance, power supply voltage restrictions, and signal handling capability of the integrated circuits.

The preceding data is based on actual measurements, care has been taken to insure reasonable accuracy. It cannot be implied through such data that manufacturing tolerances will allow devices to be shipped to maintain the peculiar distributions measured here; however, the results seem to show exactly what would be expected for the lowest cost devices sold in the U.S.A. since anything much better would be sold at a higher price. Careful study of these meas-

urements (a portion of which are shown) seem to confirm their validity, for the purposes, stated in this study.

Here is the PNP Portion of the minimum cost transistor Survey.

2N5138 – PNP Low Level Amplifier. Graded from 2N4246, 4249, 4250

Typical Unit exhibits Low Noise 0.7db @ 1 kHz I_c = 20 mA @ V_{CE} – 5 Volts

H_{FE} = 100 Typical I_c = 100 @ 10 Volts

V_{CBO} = –30 Volts Minimum

V_{CE} = –30 Volts Minimum

V_{CE} Sat = 0.3 Volts Maximum I_c = 10 mA I_b = 0.5 mA

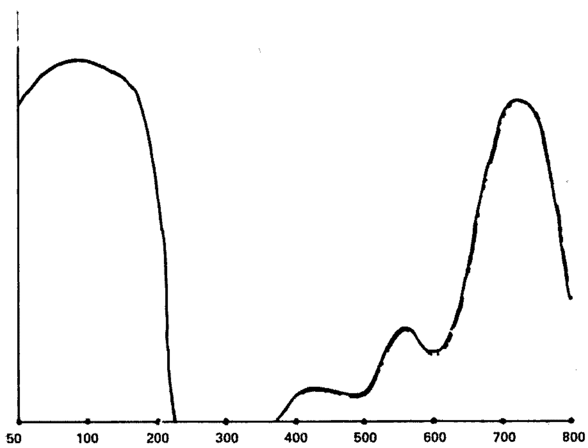
C_{CB} = 7 pF Maximum

A β Linear Transistor with good V. Sat. Useable Current Range 20 Micro Amp. to 50 mA frequency Range 50 Hz to 2 MHz. Low noise performance requires Device Selection. Suitable For Video Amplifier Service to About 4.5 MHz.

F_t up to 300 MHz @ I_c = 3 mA V_{CE} = 10 Volts

Price 11 cents.

Several hundred of these have been used. Device was compared to 2N4248. (Price 16 cents.) Results were similar. 2N4249 is 38 cents. 2N4250 is 40 cents. This series has V_{CE} 40 Volts with 4249 V_{CE} 60 Volts.



2N5138 B Distribution

2N5139 PNP High Speed Switch and *rf* AMP Graded from 2N4916, 2N4917, 2N4121, 2N-4122.

H_{FE} = 150 Typical @ 10 mA

F_t 500 MHz Typical @ 10 mA

C_{CB} = 2.2 pF Typical

V_{CEO} = –20 Volts Minimum

V_{CBO} = –20 Volts Minimum

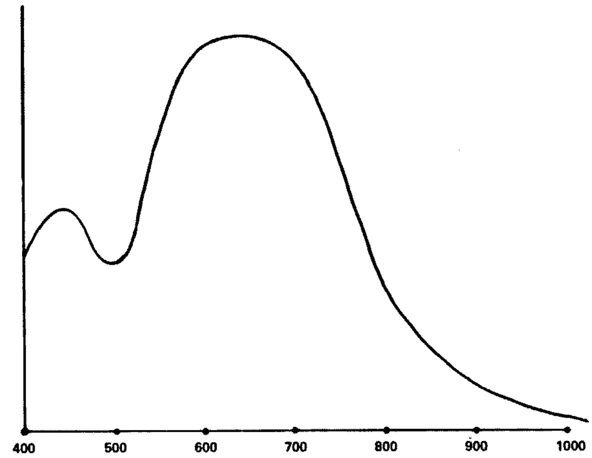
H_{FE} = 30 MIN 70 Typical @ 100 mA –10 Volts

MAX V_{CE} Sat 0.15 Volts @ 1 mA

MAX V_{CE} Sat 0.20 Volts @ 10 mA

MAX V_{CE} Sat 0.50 Volts @ 50 mA

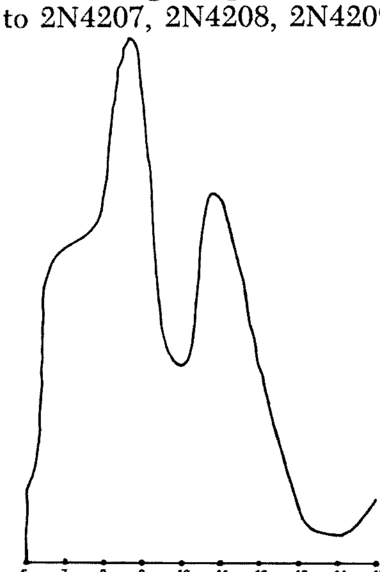
F_t was measured at spec point



2N5139 FT Distribution

A plot was made using 100 devices. Additional 200 devices were purchased. Another curve was drawn. Two more large lots were purchased. The final curve shows F_t distribution for nearly 1000 devices. The smaller lot curves were almost identical. Only one device had F_t = 300 all the remaining devices had F_t Minimum 400 Typical 660 Maximum 1000. Useable frequency range for best noise figure 1 kHz to 100 MHz on selected units. F_t remains high at 1 mA (Typical 300). Switching characteristics good. A very nice device. Price: 11 cents. 2N4916 costs 16 cents was compared. Results similar. 2N4917 is 36 cents. 2N4121 38 cents, 2N4122 41 cents. It appears only parameters comprised are breakdown voltage, and upper corner noise frequency. Used for *rf* amps, Overtone oscillators, a general purpose replacement for PNP Germanium transistors, one was to replace A 2N1142 and performed satisfactorily.

2N5140-Ultra High Speed PNP Switch Similar to 2N4207, 2N4208, 2N4209



2N5140 VCE Distribution

V_{CBO} = −5.0V MIN
V_{CEO} = −5.0V MIN

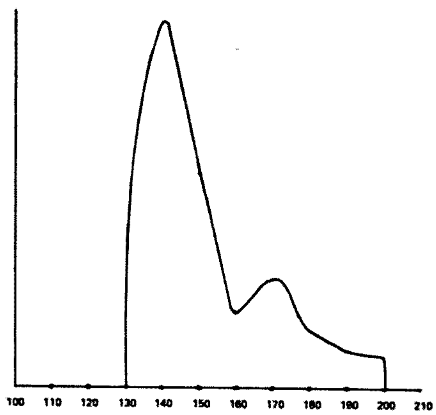
V_{CE} SAT = 0.7 Volts MAX
V_{CBO} = −6 Volt MIN
V_{CEO} = −6 Volt MIN
V_{EBO} = −6 Volt MIN
V_{CES} = −4 Volt MIN

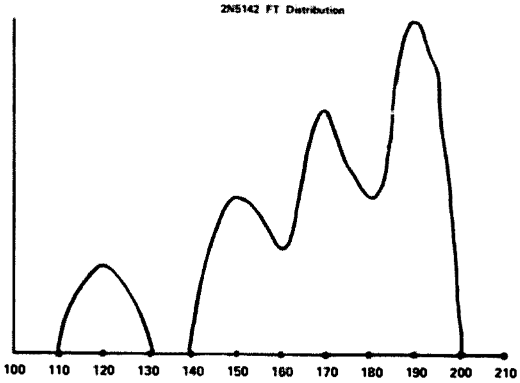
F_t of 1200MHZ Typical not confirmed by measurement. Switching parameters very wide spread. Low breakdown voltage, rather high C_{CB}. I have not found a good application for the 100 PCS I've measured. Cost is 16 cents.

2N5142—PNP High Current Switches
Toios Case
2N5143 – PNP TO-106 Case
(*Similar to* 2N3638, 3638A)
V_{CBO} = −20 Volt
V_{CEO} = −20 Volt
V_{EBO} = −4 Volt
H_{FE} Min 30 Typical 70 @ 50 mA 1 Volt
C_{CB} = 4.5 Typical 10 pF MAX
F_t = 100 MIN 190 Typical 50 mA −3 Volt

F_t falls off Between 5 mA and 1 mA significantly. Suitable for high current line drivers, medium speed switching. Good V_{CE} Sat. over current range. I use it as a voltage regulator current driver. Appears to be a low voltage 2N2905 with low β at lowered currents. It costs 16 cents.



2N5142 FT Distribution



2N5143 FT Distribution

One Other Device is worth mentioning:
2N5163 – N – Channel LO Noise JFET
Very Low Noise
e_n = 12 NV Typical e_n = 50 NV/Hz (MAX) @ 1 kHz
1.0 kHz NF = 0.1 db (Typical) @ 1.0 mA
Rds ON = 500 MAX
125 Typical
I_{dss} MIN 1 mA
Typical 14 mA
V_{ds} = 15 Volt V_{GS} = 0
MAX 40 mA
V_{SG} = 25 Volts MIN
V_{DG} = 25 Volts MIN
V_{DS} = 25 Volts MIN
I_{dss} was typically 22-26 mA
At V_{GS} = 0 Lowest was 14 mA
Highest 36 mA

It is supposed to be a very low noise unit per specs: Most are. An audio amplifier that was built using this device had no difficulty picking up several local radio stations. At 35 cents each in lots of 100, it is reasonable enough to experiment with.

Summary:

PNP transistors I was most impressed with were the 2N5138, for beta linearity, and excellent video amplifier service, the 2N5139 for all general *rf* applications, and the 2N-5140 for high speed switching. Most applications do not require higher voltage breakdown devices than this series of semiconductor devices will provide. It is hoped some individuals will consider this series suitable and incorporate these devices in planned construction projects.

I am reminded Fairchild is *not* the sole vendor source for this semiconductor series. No estimate can be made concerning quality or parameter distribution of an identical type supplied by another vendor.

An estimate can be given concerning the parameter distribution of one typist, not supplied by any vendor, without whose patience this article could not be completed, so at this time I must thank Miss Carole A. Hussar, and add this comment . . . a pretty, blond, young secretary-typist need not supply a data sheet for publication . . . none of the readers of 73 would be interested. ■

Heathkit SB-610 Monitor Scope Modifications

Ian A. Webb K6SDE
432 Rosario Dr.
Santa Barbara, Calif. 93105

Proper optimum operation of single sideband transmitters is most easily achieved by oscilloscope monitoring. As a result, the Heathkit SB-610 Monitor Scope* is appearing in more and more amateur shacks as a vital piece of equipment. As originally designed, this equipment is a versatile piece of gear. There are a couple of modifications, however, that make this an even more versatile instrument.

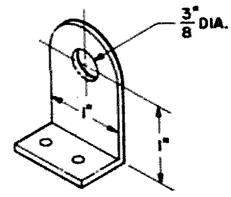
I will describe two modifications that I have made to my SB-610. Neither modification requires new front panel holes or mechanical changes to affect the resale value of the SB-610. Most owners of the SB-610 should consider at least the first modification. Those who have yet to acquire an SB-610 may wish to incorporate the modifications when they construct the kit.

Transmitter attenuation switch

This modification moves the transmitter attenuation switch from its present position in the center of the rear apron of the SB-610 to the front panel. The control becomes concentric with the present vertical gain control. With the transmitter attenuation control on the front panel, it is no longer necessary to reach behind the SB-610 to change the transmitting pattern height when changing power levels or making band changes. This is especially useful when one changes bands frequently or where a linear amplifier is often switched on or off.

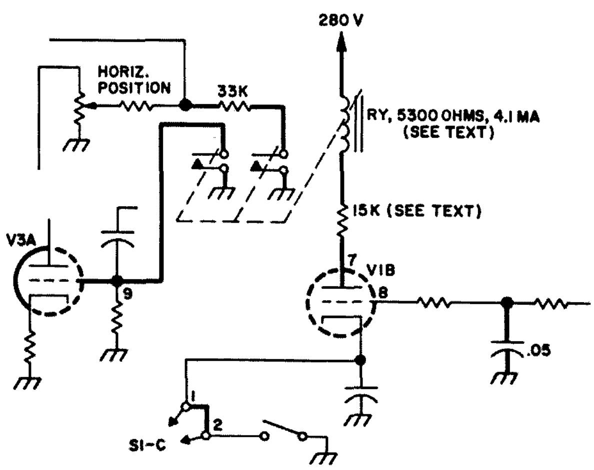
Parts required:

Concentric potentiometer element (outer unit) and shaft assembly, 100 K linear (IRC-CTS CF 13 or equivalent, see text)
Potentiometer mounting bracket (See **Fig. 1**)
Non-conducting shaft (3⁄16 inch diameter by 10 inches approx.)
⅜ inch "butch plug"
Lever knob*
Control knob split bushing*



Mounting Brackett

In this modification, the present 100 K linear vertical gain control, which is in the lower center of the front panel, is replaced with a 100 K linear concentric potentiometer. A Heathkit lever knob, matching the present SB-610 knobs, is put on this new potentiometer. This leaves a hole through the center of the vertical gain control in which to run



Modification Schematic

the insulated shaft which controls the transmitter attenuation switch which is remounted on a new bracket facing forward.

The choice of concentric potentiometer is not critical and by browsing in your local parts house stock of replacement type controls you should find a "make your own pot" selection enabling you to assemble the "outside" portion of a dual potentiometer. (I used an IRC-CTS CF-13 unit with a panel bushing about ⅜ inch long and a shaft about

*"Heathkit SB-610 Monitor Scope," *73 Magazine*, (December 1966), 54.

*Order Heathkit numbers 455-11 Split Bushing $.10 and 462-195 Lever knob $.50 (postpaid) from: Heath Company, Benton Harbor, Michigan 49023.

⅝ inch long which I cut to exactly fit the Heathkit lever knob.)

Remove all three wires to the lugs of the old vertical gain control (AJ in the SB-610 manual) and remove the old control and knobs keeping the wires in order so they may be soldered to the new control. Before mounting the new pot, be sure that the knob shaft will extend just far enough to allow you to mount the new lever knob on it. Do any cutting of the shaft before mounting the potentiometer to prevent damage to the front panel of the SB-610. Mount the new control and resolder the wires to the corresponding lugs of the new control.

Fabricate a bracket as shown in **Fig. 1** and refer to the photos to see mounting details. (If you are lucky as I was, your junk box will yield a suitable bracket.) Unsolder the wire from the coaxial connector to the lug 4 of switch BD, the transmitter attenuation switch, and unsolder the capacitor which runs from terminal strip G, lug 5 to terminal 5 of switch BD. You can now remove the switch from the back apron. If you wish, fill the empty hole in the back apron with a "butch plug."

Mount the new mounting bracket in line with the old hole in which the switch was mounted. Allow enough room for the switch to be remounted between the new bracket and the back apron. Mount the switch and reattach the wire from the coaxial connector to terminal 4 and the capacitor to terminal 5 of the remounted switch. Orient the switch so this can be accomplished with the least difficulty. Be certain that no components stick up far enough to interfere with the case when it is replaced over the Monitor Scope.

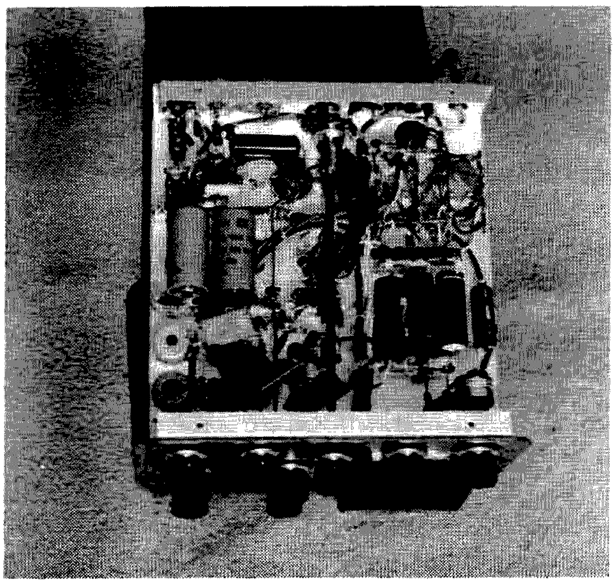
Attach the shaft coupler to the switch shaft and insert the 3/16 inch non-conducting shaft extension from the front panel into the hole through the vertical gain control running it back to the shaft coupler. Carefully move any parts that interfere with the shaft. The large .25 mfd capacitor near the shaft coupler between the tube socket (V3) and the terminal strip G may need to be relocated to provide sufficient clearance. A metallic shaft extension is *not recommended* due to the possibility of accidental contact with parts on the chassis.

When the shaft has been properly mated, make a small shim from a piece of scrap or tin can to reduce the ¼ inch coupler on the switch to accept the 3/16 inch shaft extension. With the shaft in place measure ½ inch beyond the lever knob mounted on the vertical gain control and remove and cut the shaft at this point. Mount the shaft firmly, tightening the coupler. Use the new split bushing inside the original knob removed from the vertical gain control to firmly fasten the knob onto the shaft extension flush with the lever knob.

The SB-610 will now operate exactly as it did originally. It is now possible to select the vertical gain when monitoring a received signal using the lever knob and to change the transmitter attenuation using the large original knob. It is no longer necessary to reach behind the SB-610 each time the linear is turned on or off or each time you need attenuation changes when switching bands.

Clamp Modification

This modification should appeal to those people, myself included, who believe that the main virtue of the SB-610 is the monitoring of one's transmitted envelope using the internal sweep. If you use the internal



Top View

sweep *without also monitoring received signals* during standby periods, the trace of the SB-610 will remain a static baseline of high intensity since the clamp circuit is inoperative in this mode. This can cause a burned scope face if the intensity is high enough for good monitoring of peaks in a brightly illuminated room. I decided that I would like to remove the trace from the scope face automatically when the transmitter is turned to standby. This could be done using the relays that switch the rig from transmit to receive, but since my rig is a transceiver

that I also use when mobile, this would involve additional connections to attach and remove each time I switched from base station to mobile operation. My modification accomplishes the clamping of the trace with no additional connections to the transmitter or receiver.

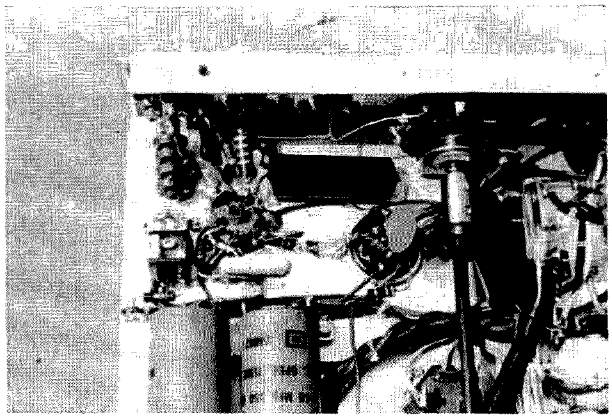
Parts required:

Capacitor, .05 mfd, 50 volts
Resistors: 33K, ½ watt and resistor in series with relay coil (see text)
Sensitive plate relay, DPST, N.O., (Lafayette Radio 99H6093, DPDT, 5300 ohm, 4.1 ma., 4 oz., shipping weight, $2.95, Lafayette Radio, 111 Jericho Turnpike, Syosset, L.I., N.Y. 11791) See text for details.

The relay I used, was from my junk box. Lacking a suitable relay, the one listed in the list above is suggested. It may require ingenuity to mount some relays, but a small bit of epoxy will do wonders if properly applied.

Fig. 4 shows the circuit modifications to be made. The dark portions of the circuit are additional components or modifications. The clamp tube, V1B, is turned into a relay amplifier. Relay contacts are used to pull the trace off the screen by shorting the horizontal position control through a 33 K resistor. A second set of contacts grounds the grid of V3A to stop the sweep. If the sweep is not disabled, the left portion of the trace will still be on the screen. Pins 1 and 2 of the front panel sweep control are jumpered so that the "pull for clamp" control will work in the internal sweep position of the sweep control as well as in the other sweep positions. When this modification is made, the SB-610 will operate as originally designed in the RTTY and *rf* Trap positions of the sweep switch. The clamp will also work in the internal (Int.) position of the sweep control when the "pull for clamp" control is pulled out. The clamp switch may be pushed in so that received signals may also be monitored as originally designed.

The .2 microfarad capacitor on terminal strip H adjacent to tube socket VI is changed to .05 microfarads to allow 1 to 2 seconds before the trace leaves the screen. This capacitor need not be changed, but the time for the trace to leave the screen will be in excess of ten seconds if it is not changed. Remove the capacitor from strip H and replace it with the .05 mfd capacitor if you desire this change.



Bottom View

The left hand lug of terminal strip U, near the chassis edge was originally unused. Remove the blue wire at pin 7 of VI and solder it to this unused lug of terminal strip U. On the back of the front panel, solder a jumper wire between lugs 1 and 2 of the sweep switch.

Mount the plate relay in the space between the tube socket VI, terminal strip U and the edge of the chassis. If your relay can be mounted with screws as could my junk box relay, that is fine; otherwise you may have to use some ingenuity and perhaps some epoxy to mount the relay.

From one set of relay contacts (closed when the relay is operated) run a wire to a convenient ground point such as the mounting lug of terminal strip U. From the other contact of the set, connect the 33 K resistor to the blue wire which you soldered to the previously unused lug of terminal strip U near the outside of the chassis.

From the second set of contacts (also closed when the relay is operated) run a wire to ground. From the other contact of this set, run a wire to pin 9 of tube socket V3A which is the tube socket near the shaft extension. This set of contacts will now ground the grid of tube V3A when the relay is closed and stop the sweep.

Run a wire from one end of the relay coil to the 280 volt bus. I ran the wire to the junction of the 40 mfd capacitor; 15 K, 1 W resistor; 1 K, 1 W resistor; and 20 mfd capacitor. This is near the center of the chassis on capacitor K, pin 3.

Temporarily, attach the remaining end of the relay coil to pin 7 of VI through a resistor. (This resistor should be nominally 15 K ohms for the relay in the parts list.) The resistor should be selected so that the relay used just pulls in reliably when the

clamp switch is pulled out, the SB-610 turned on, and no *rf* signal is applied. In any event, the plate dissipation of the 6BN8 relay amplifier should not exceed the maximum rating of 1.7 watts. The total resistance of the relay coil plus series resistor should be at least 10 K. (If you use a junk box relay, measure the voltage from cathode to plate, and the current through the tube when the relay is pulled in. The product of the voltage and current—in amperes—should not exceed 1.7.)

This completes the wiring of the modification. Check the wiring against the schematic in **Fig. 4.** Carefully plug the SB-610 in with it still out of the case and let it warm up. Check to see if the relay operates when the "pull to clamp" switch is pulled out and the sweep switch is in any position. If the relay does not operate, first recheck the wiring to make sure it is correct. If the wiring is correct and the relay will still not pull-in, reduce the value of the resistor from the relay coil to pin 7 of VI until the relay reliably pulls in. This will assure that minimum plate dissipation occurs in tube V1. When this value is found, solder in the resistor permanently.

When the "pull to clamp" switch is pushed in, the relay should drop out. The trace will then appear on the face of the SB-610 and it should operate normally.

Set the sweep switch to Int. and apply a small amount of transmitter *rf* to the connector at the rear of the SB-610 while the "pull to clamp" switch is out. The relay should release and the trace should appear to allow normal transmitted signal monitoring. If the trace does not appear and the relay drop out, increase the *rf* signal. When the *rf* is removed by turning off the transmitter, the trace should disappear after 1 to 2 seconds. If the trace has not moved completely off the scope face, it may be necessary to decrease the value of the 33 K resistor. If the sweep still continues when the trace is off screen, the grid of tube V3A (pin 9) is not being shorted to ground through the relay.

I have operated my SB-610 24 hours a day for days at a time and experienced no difficulties. You must now remember to turn off the power switch after operating, for you no longer see the green trace on the screen to remind you that the SB-610 is on.

VHF FM Station Control

Being addicted to the use of FM on the VHF ham bands, I decided to establish a system of communications equipment for two of the most popular bands.

In the area where I have been living 2 and 6 meter FM are the most popular.

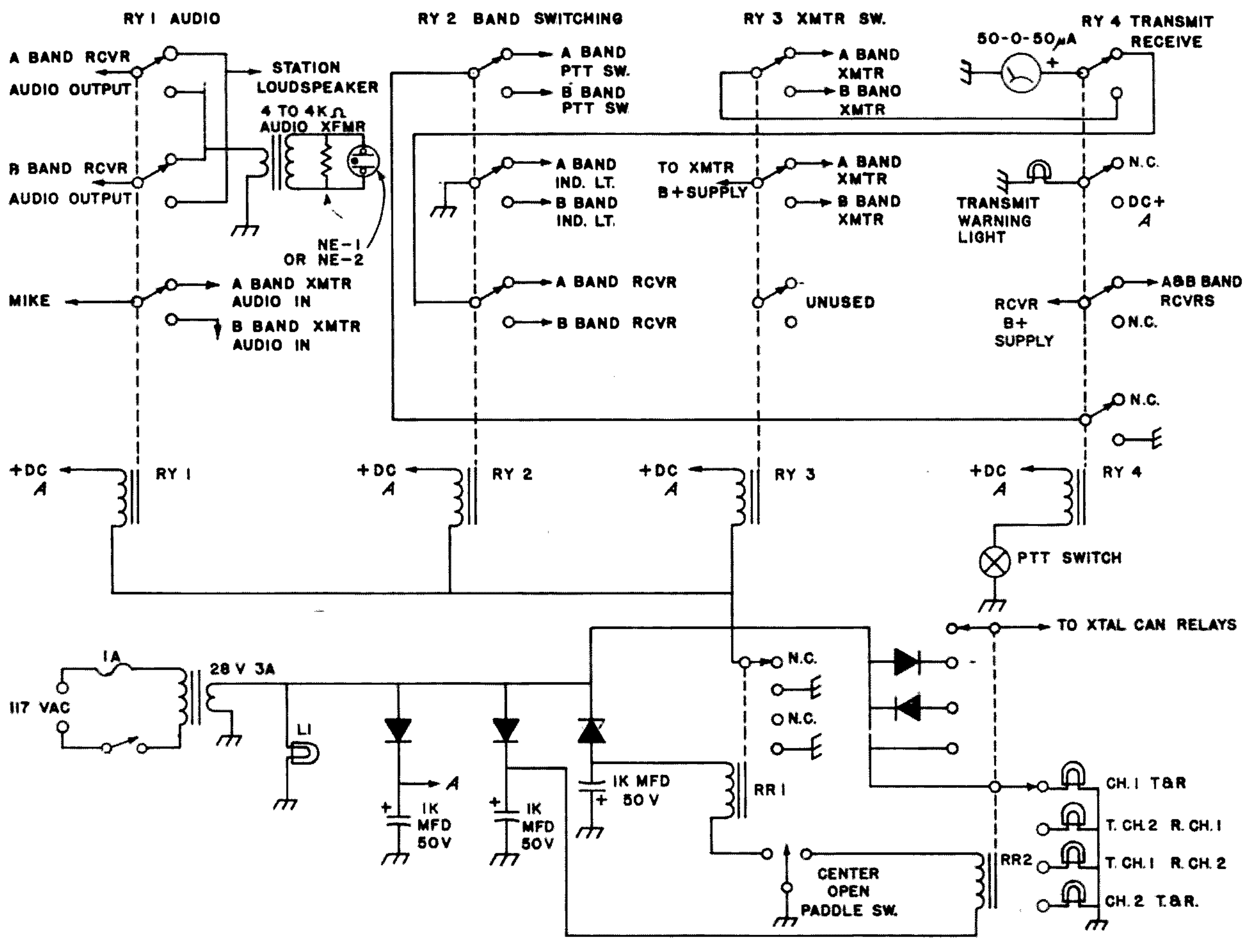

Fig. 1. The station control unit. RR1 changes bands each time the paddle switch is pushed to the left, RR2 changes channel setup in either band when paddle switch is pushed to the right. Lamps in lower LH corner of the schematic indicate which of four channel tuning schedules is in effect.

The unit to be described has provisions for two band operation as well as two separate transmit and receive frequencies on each band.

The unit makes use of surplus parts and is very straightforward in its operation.

There are two rotary-ratchet relays in use, one is set up so that every other terminal is grounded. When this relay is stepped, it alternately energises or deenergises relays ry1 through ry3. These relays take care of the bandswitching function. Provision is also included for automatic switching of metering. The other rotary relay applies a series of pulses to crystal-can relays in the various transmitter and receiver units. The first step applies no voltage to the relays. The second step applies a positive pulse at 28 vdc to the relays triggering one set. The third step applies a negative pulse to the bank of crystal-can relays triggering one set and releasing the other. On the fourth and final step 28 vac is applied to the bank of relays triggering both sets. This works out very well in conjunction with a local repeater, allowing either direct contact or contact through the repeater.

A fourth relay Ry4 has the duty of switching the receiver voltage for muting as well as the metering and keying the PTT. This relay is keyed to ground through the PTT contacts on the microphone. The PTT circuits of both transmitters are keyed every time the PTT is energised, however only the selected transmitter is operational as the power is switched through a set of contacts on the band s selector relay.

This unit has been in use for several months and works out very fine. It saves wear and tear on the operator during band switching operations.

Also included is a second band monitor. Both receivers are running continuously. One is feeding the speaker while the other is feeding an audio output transformer hooked up in reverse. If there is any audio present on the second band it will light 19.

Channel switching is done by means of small dpdt relays. These relays, due to their physical size are called "crystal-can" relays.

One is used in each transmitter and receiver and wired so that the wipers connect the crystal across the the crystal socket. The relay used in t this manner reduces problems, due to the fact that there is only one crystal in the circuit at any one time. One lead is connected in parallel with all other relays and goes to the wiper of Rry2. The other lead of the coil goes to ground through an appropriately polarized diode. It is well to have like relays keyed at the same time. That is both transmitter and both receiver relays keyed together. A provision is included for lamps to indicate which channel is in use at any one time and a chart is easily made to call out just what each lamp indicates.

The purpose of this is not so much for construction of exact duplicates but to open the doorway for thought and design to meet your own personal requirements.

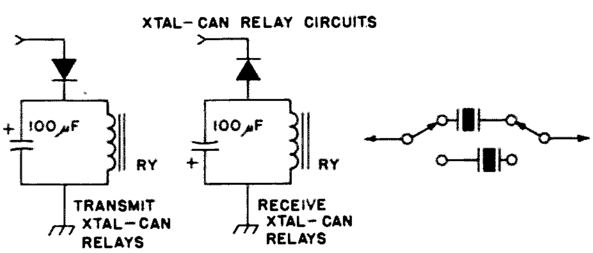

Fig. 2. Series diodes determine applied voltage polarity that will operate the crystal-can relays. With added capacitors, relays will operate reliably on ac, which is applied during some Station Control settings. Note relays switch both sides of the crystal circuit.

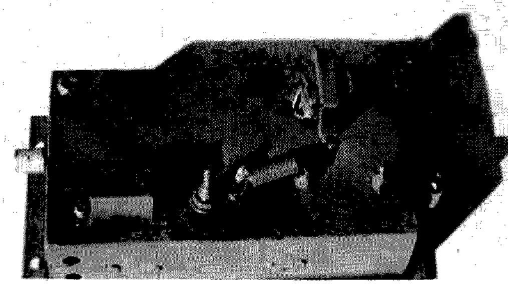
A Simple Portable Rig For Six

With "mountain topping" becoming a popular sport on the VHF bands, a low power portable transmitter for 50 MHz can be a handy item. This article describes such a transmitter that is not excessively difficult to build and provides a good signal on six meters.



The Circuit

It was finally decided that the one watt power level offered a fair compromise between battery weight and power. Only two stages are needed to generate the desired power, and this simplifies construction. Both the oscillator and amplifier are power modulated for maximum audio "punch." The modulator is a PA-222 one watt integrated circuit amplifier. With the addition of a few external resistors, capacitors, and a transformer, this unit offers one watt of audio at a price comparable to commercially manufactured amplifiers. It is surprising that integrated circuits have not become much more popular with the amateur fraternity.

The RF section was adapted from RCA designs, and is a standard configuration. It was necessary to hold the supply voltage to 22½ volts to prevent destruction of the transistors. It is theoretically possible to generate instantaneous voltage four times the supply voltage in a modulated transistor transmitter. In this case this rating is exceeded, but the theoretical maximum is usually never reached.

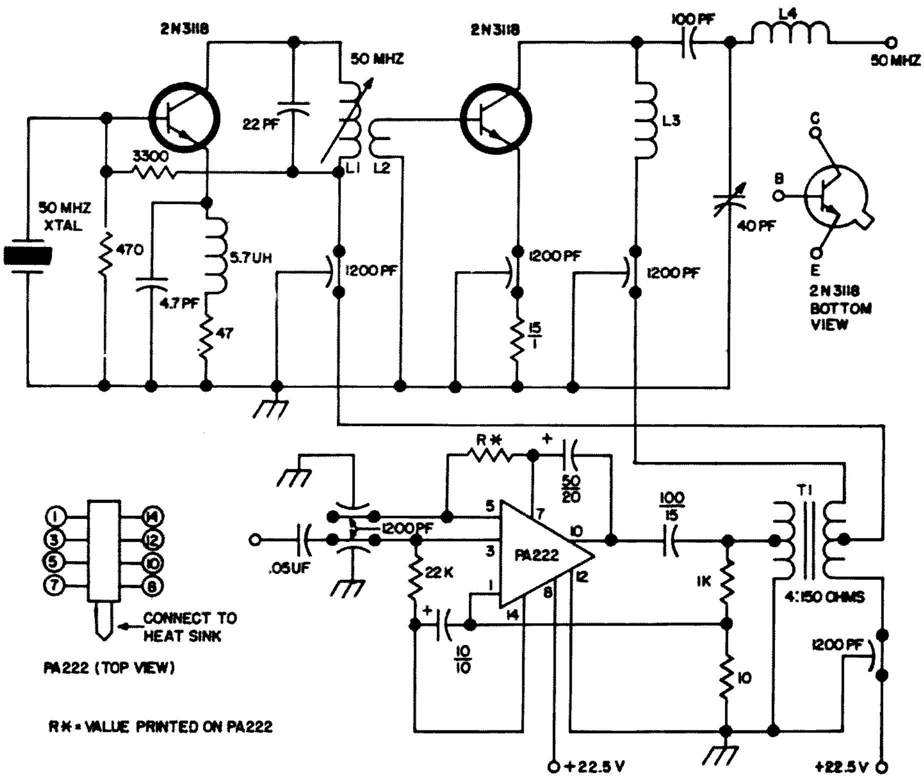
In order to obtain full modulation the oscillator must be modulated along with the final. Careful tuning of the oscillator can minimize FM, but for optimum results, it would be best to add a driver stage so that the oscillator would not be modulated. However, in this case, simplicity and power consumption were more important, and careful tuning gave very good results.

Construction

The transmitter was built in a small four section copper plated box that was obtained from a piece of surplus equipment. This type of construction is very rugged and provided optimum shielding. Standard VHF construction procedures were followed.

An unexpected problem arose in building the modulator. The General Electric PA-222 is just not meant for this type of construction, and one of the leads broke off. However, after some scraping and soldering, a connection was made to the broken lead. It is amazing how much abuse the IC took with no apparent damage. In future projects a printed circuit board should be used.

As a final step, the inside circuitry was painted with anti-fungus varnish made by GC Electronics. This is a reasonable precaution considering the outdoor use that this transmitter will be subject to. For the same reason, lock washers were used wherever necessary to insure mechanical dependability. The cover over the crystal and socket is an unusual feature. It is made of brass, and designed specially for this



Parts List

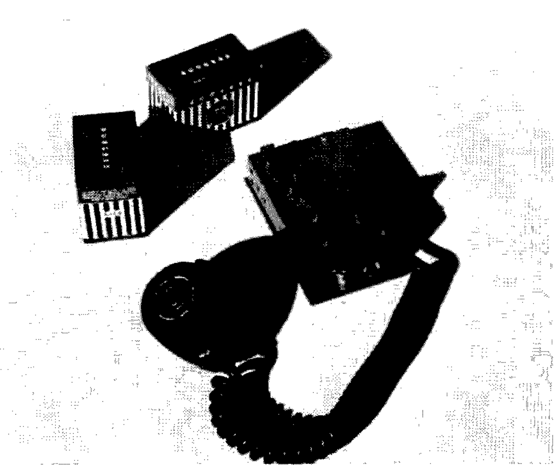
L1 .... six turns number 22 on 3/8 inch diameter slug tuned form
L2 .... two turns insulated hook-up wire on L1
L3, L4 .... ten turns number 18 3/8 inch diameter close wound
Xtal .... 50 MHz overtone type crystal
T1 .... Thordarson TR-21

Note:
R* is the value printed on the top of the PA-222. The tab on the PA 222 should be soldered to a suitable heat sink. Resistors are half watt except where noted. Capacitors are disc ceramic except for 1200 pF feedthrough capacitors and output tuning capacitor which is a piston trimmer.

use. Its manufacturer is unknown, but in a situation where one frequency is used, it was reasonable to protect the crystal even if it made frequency changing difficult.

Operation

The first problem that arose was in the oscillator coil. Some experimentation was required to insure easy starting and frequency stability under modulation. The circuit should be tuned to a higher frequency than where maximum output occurs. The final amplifier also had to be detuned slightly to obtain "upward" modulation. The slight reduction in power will not be noticed, but the distortion can seriously impair readability. It was also discovered that the large current swings in the modulator caused a serious voltage drop during modulation peaks. In order to eliminate this it was necessary to use separate power sources for the RF unit, making two batteries necessary.



Transistor transmitters tend to generate harmonics, and this one is no exception. For sporadic mobile and portable operation, the operator probably will not worry about this, but if operation is centered in a heavily populated permanent location, the operator may wish to check for harmonics. A harmonic does show on the GDO in the middle of the FM broadcast band, but no trouble has been reported. This is probably due to the lack of FM receivers in this locality, and the harmonic signal drops off within a few hundred feet of the transmitter. If problem do arise, standard TVI prevention methods ıould be employed.

Results

In an unscheduled test a mobile station was contacted. Before being told, he was unaware that the one watt transmitter was being used, and he thought it was the thirty watt base station transmitter.

Even with its relatively low power, this transmitter will provide a reliable high quality signal for the mountain-topper who likes to hike to those "hard-to-get-to" spots.

Using FET's in Burst Generators

What's a burst generator good for you say? It's ideal for pulse testing of transistors at high peak power levels, pulse modulating transmitters on UHF or SHF or for other experimental work (or just for fun). **Fig. 1** shows an *rf* burst. V_1 is the sinusoidal "on" voltage and V_2 is the off (leakage) voltage. I call the ratio V_1:V_2, Rv (for voltage ratio). Ideally if the sine

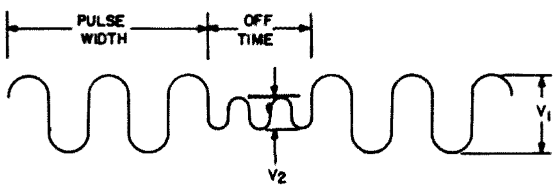

Fig. 1. V1 is the "on" voltage; V2 is the "off" (leakage) voltage.

wave were 100% modulated by the pulse, the leakage voltage (V_2) would be zero. Rv then equals infinity. But since a practical modulator cannot be perfect, there is some modulator output during the off time.

Immediately when I thought about a burst generator, I decided on the circuit of **Fig. 2.**

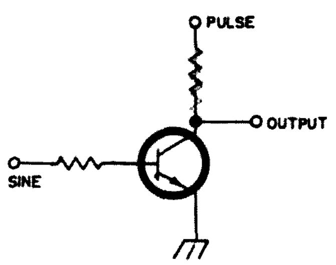

Fig. 2. The simplest and cheapest pulse modulator; however, there is a dc component in the output.

It is simple but has a drawback. It has a dc component in the output. That is, its output is like that of **Fig. 3.** To eliminate that problem let's switch to the circuit of **Fig. 4.** This circuit might seem reasonable at first glance (there would be no dc component in the output), but it fails for this

Fig. 3. Idealized output of circuit in Fig. 2.

reason. The collector-base junction of the transistor must be reverse biased for proper operation. This condition is not met (for instance, during the negative portion of the sine wave the collector is minus and the base is plus). Furthermore, because of the saturation voltage of the transistor, this circuit may not act as a very good switch anyway (neglecting the biasing). That is, suppose the sine wave voltage input is perhaps one-half volt, and the transistor saturation voltage is two-tenths of a volt. We loose a large percentage of our voltage across the transistor.

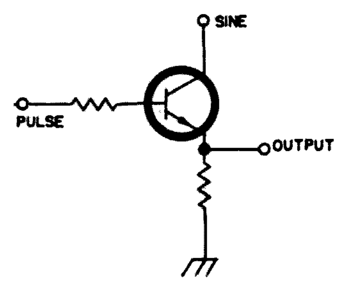

Fig. 4. This circuit is simple, but the transistor will not be biased for proper operation.

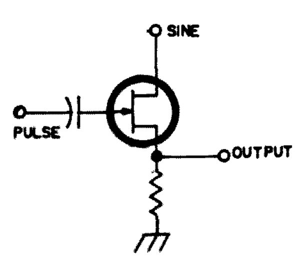

Fig. 5. Basic FET modulator.

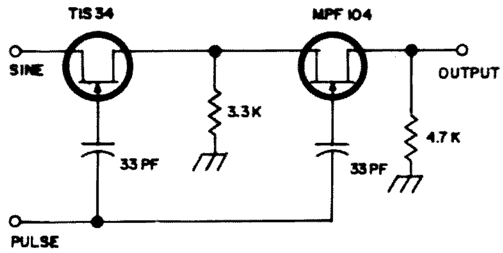

Fig. 6. Final burst generator design.

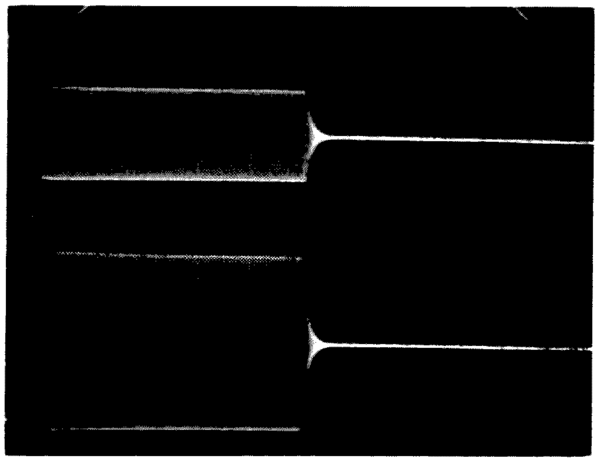


1 ms rf burst of 200 kHz (top trace) and after amplification (bottom trace).

At any rate, these problems can be completely eliminated by using a junction field effect transistor (JFET). The JFET measures many megohms between source and drain when cut off and the on resistance (channel resistance) on some of the good units runs only a few hundred ohms. The FET is now used as in **Fig. 5.** The Motorola MPF104 is excellent at $1.00, and the Texas Instrument TIS34 is equally good at $1.10. Both are available from Newark Electronics and several of the other large wholesale outfits. By using two burst generators in cascade I was able to get a higher modulation percentage (less leakage). Because of what I had at the time I used one Motorola unit and one TI unit. A pulse of ten to fifteen volts is required (remember to measure pulse height with an oscilloscope). To avoid damage to the transistors do not use excessive pulse voltage.

The circuit values may not be optimum for your application, so some experimentation may be in order. Even so, Rv for this circuit is excellent and typically runs 300 or 400. This setup can easily be used from ultrasonic frequencies up to ten mHz or so. Happy bursting! . . . K3VKC

TWO METER CONVERTER

for the Swan 250 or Anything Else

L. J. Hemis—K3VLQ
2227 Eastern Ave.
Wesleyville, Erie, Pa. 16510

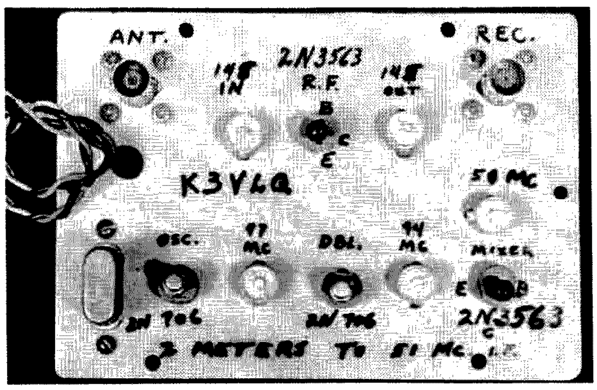
With the number of Swan 250's on the air, there are no doubt quite a few fellows who would like to plug in a converter ahead of theirs to see what's happening on the two meter band. With these fellows in mind, we put together this transistorized job.

For some, it may seem like a rather ambitious undertaking, considering the printed circuit board, but we tried to keep the difficult work to a minimum on the board, and, if it's your first etched board, it's a good project to start on.

A careful study of the underside of the board (foil side) will show that most of the foil remains, and only portions at the trimmer capacitors, the transistor sockets, and one long skinny U-shaped strip for the plus voltage were etched out. This leaves the rest of the foil for ground potential, and leads can be soldered up short, (a necessity at these frequencies).

A little trick we used on this board is worth passing on,—the matter of masking. Most manufacturers of cellophane tape are now making a rough or matte finish tape which can be written on with a pencil. Cover the copper side of the board with this tape, press it down tightly to be sure all the copper is covered, and lay out your work with a pencil. Using a razor blade or sharp knife, cut out the sections of tape *where you want the copper removed,* and lift off these sections of tape. Leave the rest on, because this is your "resist" for the acid.

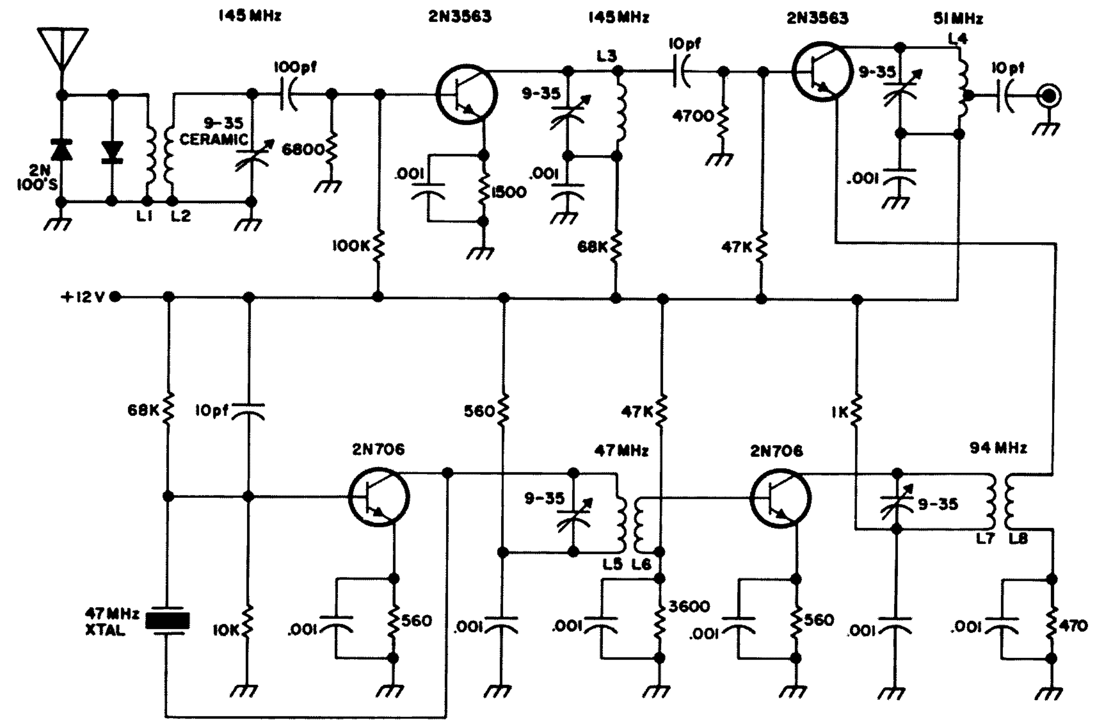
Drop the board in a ferric chloride solution for 45 minutes to an hour at room temperature, and you can watch the progress of the job. Use stainless steel, plastic or hard rubber tongs to handle the part in the acid.



When etching is completed, remove from the acid, flush in running water, and remove the masking tape. Look it over carefully with a magnifying glass, to make sure all the copper is removed where it should be. Any small portions you wish to take off now can be scraped off with a sharp knife or a razor blade.

The ferric chloride is a brown crystal that mixes easily with water. We use 1580 grams of crystals per gallon of water. You won't need much more than a pint in a glass, rubber or plastic tray. Use caution in handling this stuff as it leaves a brown stain that you won't get off a white shirt. The solution keeps well, and can be used over and over again until the etching time becomes too long. By the way, the etching process is accelerated by heating the solution to 160-180 degrees Fahrenheit, if you are in a hurry. If you try a printing shop that does photo-engraving, they may even give you some of the solution already mixed.

Printed circuit board stock is generally advertised in about a half dozen ads in the



back of this magazine. After you've etched a few boards like this, you'll wonder how you ever built anything without them. You can cut it with tin snips, heavy scissors, or a photo paper trimmer. Note the 1" high shield between the R. F. and the oscillator sections on the converter,—cut it, break it, bend it, and tack solder it in place,—cheap, quick and easy.

While we're talking about that shield, look below the "Ant." connector on the photo. Follow the dotted line to the "plus" lead, which is the long skinny U-shaped strip mentioned earlier. You will note that the bottom of the U passes under the shield. This portion of the shield is nibbled out to clear the "plus" lead, so that it won't short out, and doesn't show on the photo. Nibble out clearance with your diagonal cutters. You will also see a coupling capacitor going right through the shield at the bend. A small drill

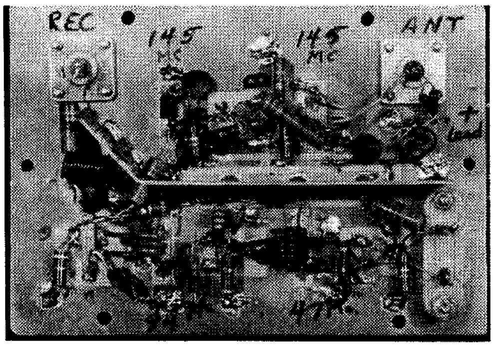
or pocket knife will cut that one for you.

Some experienced builders may question the labelling on the rf and mixer sockets, so an explanation is in order. Considerable experimenting was done on this prototype, with other transistors, including FET's and the leads may seem slightly scrambled. We didn't intend this to be a set of kit-building instructions and hope those who try to duplicate this converter will use a little judgment. The sockets were also used because we intended to do a little experimenting, and you can etch your board to solder your transistors in permanently, if you like, and save the price of the sockets. Since this was an experimental job, we left two of each type transistor in to show that they will work. If you prefer, use 2n3563's all the way through, or 2n706's all the way. Either type, or both are from Poly-Paks at four or five for a dollar. The crystal is also surplus, from JAN Crystals, and picked from their list of available frequencies for about a dollar. This one is for 47.0035 MHz. If you want to throw money around, order one for 47 MHz and it will cost you about $6.50. Personally, I can't see it. We might also urge you to buy a grid dip meter, if you don't already have one.

While on the subject of grid dippers, you will note that the trimmer capacitors are mounted so that they are accessible from the top of the converter, with the coils soldered directly to them on the other side



of the board. The coils were wound on the shanks of twist drills, and are self-supporting (see L-1 + L-2 near the "ant." connector in the photo).

The final tune up procedure used in developing this converter started with the 47 MHz oscillator. After you get it going, peak up the doubler, and remove power. Grid dip the rf and mixer coils, and it should take right off. A buddy on two meters is a big help, and once you get an on-the-air signal to peak up on, you've got it made.

We have a 500 kHz crystal calibrator in our Swan 250, and found the 145.06 MHz signal of a nearby Tech right where he was supposed to be the first time up. I guess we had the law of averages with us on that one.

For power, we use a home-brew supply, and can vary the voltage for maximum gain. Once set, voltage and trimmers need little attention. These transistors seem to work well in this configuration on anything from 3 volts to about 18 volts, and there we started to lose it. The 12 volt dc relay supply on the Swan Power supply should work fine, although we haven't tried it and can't guarantee it. A 9 volt transistor battery should let you hear something. Some day we might even stick a meter to this thing, just to see how much current it does draw! Anyhow, it works fine.

From past experience, we found that after publishing an article of this type, we usually get letters. We're more than happy to answer any and all, if we can, if you are having trouble. Just be sure you are having trouble that can't be answered with a little common sense, or a quick look at a reference manual. If you write, please include a stamped self-addressed envelope, and if we don't forget to answer too many, and can get a few evenings away, we plan to whomp out a heterodyne unit, to put the Swan on two-meters, sideband and AM.

. . . K3VLQ

"Q", "Q", Who Got "Q"

This nice article would have been more attractive if some of it had not been inadvertently omitted. If you are thinking about building this little instrument, turn to our October issue, page 82. First error appears in **Fig. 1.**

That can be corrected by drawing a line from the Xtal Osc. directly to the 100:1 Divider. Now the meter can look at the input **or** the output merely by turning the switch to left or right and without disturbing the operation of the circuit. This is the basic test of comparing excitation against response to determine Q.

And here are the parts not described in the schematic of **Fig. 2.** This will answer questions about transistor and diode types, and the values of CI, C2, and C3:

CI—Erie 557-000-39R, 5-25 pf.
C2—Centralab 858S-1000, 1000 pf.
C3—365 pf, see text.
C4—4-10 pf vernier, see text.
D1 & D2—1N97 type diode
R1—25K linear composition, Set Level, with switch.
R2—1K linear, Meter Zero.
L1—20 microH, Miller 41A225CB1
Q1—Fairchild SE2001 (2N3563)
Q2, Q3—Fairchild SE6002 (2N3566)
M—100 microA. meter.

Finally, the table of **Fig. 3** applies to a piece of #816 Airdux, 16 turns per inch, one inch diameter, leads one inch long.

This is cut to 34 turns and used to make up the test inductor shown. And now you can proceed with the test setup of **Fig.** 4 for Q calibration but a word of warning is in order.

That is, if you use surplus resistors be certain they are not wirewound construction, or film resistors corrected to value by cutting a spiral groove in the film. Either arrangement will be more inductive than the composition resistors Votipka used in his original work, and will bring you to misleading results. Good luck on this simple test instrument!

(*Answer on page* 88)

VSWR-An Outmoded Parameter

As it is not possible to obtain a perfect match between a transmission line and an antenna, all the incident power cannot be transfered to the antenna, and that part which is not transferred is reflected along the line to the transmitter.

The better the match, the smaller the ratio of reflected power to incident power. This ratio can be measured with a reflectometer and is usually expressed in terms of voltage rather than power.

The voltage reflection coefficient is designated Γ (Gamma) and is given by:

$$\Gamma = \frac{\text{E reflected}}{\text{E Incident}} = \frac{[\text{Power Ref.}]}{[\text{Power Inc.}]}\frac{1}{2}$$

from which it is seen that the ratio of reflected power to incident power is given by Γ^2.

As Γ^2 provides an excellent criterion of the 'goodness of match' there is little further to be gained by making other measurements, but more of this later.

When power is reflected from an antenna, standing waves of voltage and current are set up on the transmission line and by measuring the ratio of maximum voltage at any point to the minimum voltage at a point one quarter wavelength away on either side, we get a parameter called the VSWR—voltage standing wave ratio. (The voltage ratio rather than the current ratio is measured because it is easier to measure voltage than current with the test equipment used).

It should be noted at this point that the absolute values of maximum or minimum voltages are in themselves quite meaningless and tell us nothing about the degree of mismatch. Like Γ, VSWR is a function of the degree of mismatch, and is related to Γ by

$$\text{VSWR} = \frac{1+\Gamma}{1-\Gamma} \text{ and } \Gamma = \frac{\text{VSWR} - 1}{\text{VSWR} + 1} \text{ so}$$

that each can be derived from the other.

Although VSWR can be measured with a higher degree of accuracy than Γ, it can only be measured directly by using slotted line techniques. Unfortunately this is only possible where the frequency is such that the portion of slotted waveguide used in measurements is at least about ten wavelengths long. This restricts the measurement of VSWR to microwave frequencies, where wavelengths are in the order of centimetres.

The reader, at this point, is no doubt asking the sixty-four-dollar question: How is it then that amateurs measure VSWR on amateur bands well below microwave frequencies?

The answer is—they don't! As mentioned previously, VSWR can be derived from Γ, and that is exactly what is done. VSWR meters used on the ham bands are simply forms of reflectometers with the meter calibrated in terms of VSWR and so we come to the next question: Why, after measuring Γ, do we go to the trouble of converting to VSWR?

Why, indeed?

Once Γ has been measured, we know all there is to know about the line/antenna match; going a step further and converting to VSWR tells us absolutely nothing more than we already know about the 'goodness of match'!

Let us assume that we are making some adjustments at the antenna end of a transmission line. The first adjustment gives a Γ of, say, 0.2. This means that $(0.2)^2 = 4\%$ of the incident power is being reflected. A second adjustment gives a Γ of 0.5 indicating that $(0.5)^2 = 25\%$ of incident power is reflected. In other words, an increase of Γ from 0.2 to 0.5, a factor of 2.5, increases the proportion of power reflected by a factor of $(2.5)^2 = 6.25$ i.e. from 4% to 25%. We can say that the second adjustment is 6.25 times worse than the first.

Now let us consider the foregoing in terms of VSWR.

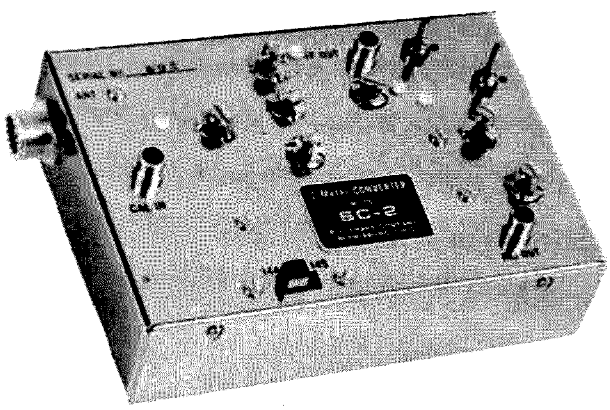
With a Γ of 0.2, VSWR $= 1+\Gamma/1-\Gamma=1.2/0.8=1.5:1$. A Γ of 0.5 gives a VSWR of $1.5/0.5=3:1$. Although the VSWR has doubled, the actual mismatch is 6.25 times worse.

From many conversations heard over the air, it is evident that most amateurs would assume that with a VSWR of 3:1, the ratio of reflected power to incident power is twice as great as that with a VSWR of 1.5:1, whereas, as we have seen, it is actually 6.25 times greater. In this writer's opinion, the time has come for amateurs to abandon the use of VSWR and to start using the much more informative and realistic Γ. Let us leave VSWR where it belongs—to the microwave bands.

Perhaps when this switch is made, we shall never again hear amateurs talking of VSWR's of 'less than one'! Sid Gould VE2AXQ

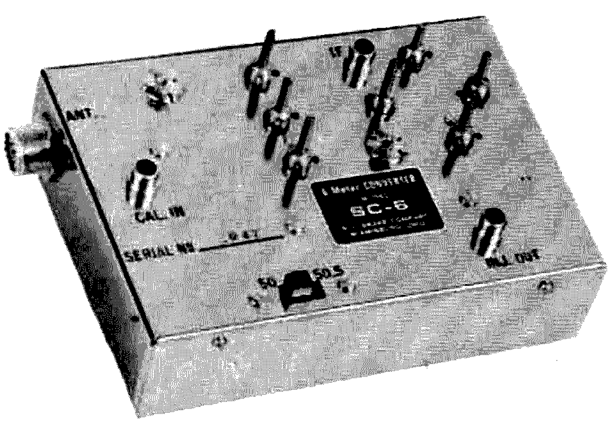
Drake VHF Converters

Kayla Bloom W1EMV
Dublin, N.H. 03444



Drake has entered the VHF market with one of the nicest packages I have ever seen. As usual, in recent Drake equipment, the design of the cabinet is beautiful. They have developed a new finish to their panels which makes it virtually impossible to scratch them.

The unit tested consists of the SC-6 and SC-2 converters, the CPS-1 power supply, and the SCC-1 VHF crystal calibrator, all housed in the CC-1 Converter Console. Each of the units may be purchased separately, but when put together in the console they make a complete VHF converter unit.



The console is designed for easy installation of the separate converters and power supply. The units plug in to the console cabinet so as to engage both the power plug and the on-off switch fork. At this time, only the units mentioned are available, but the console has room for a third converter which will be available in the near future.

Getting to the performance angle of the converters, I have been hearing signals which were unreadable in the past. Consistently, not just due to good conditions. Signals are good on 2 meters from New Jersey (350 miles away) and the Boston, Cape Cod area are S9 and better. This is covering a distance of 80 to 110 miles. There is an old saying in ham radio . . . "you can't work them if you can't hear them," but at this point it works the other way. I hear them, but can't work them.

I have to admit to having a better than average VHF location, being 1450′ above sea level, so it is all down hill, but my 2 meter beam is only 20′ above ground.

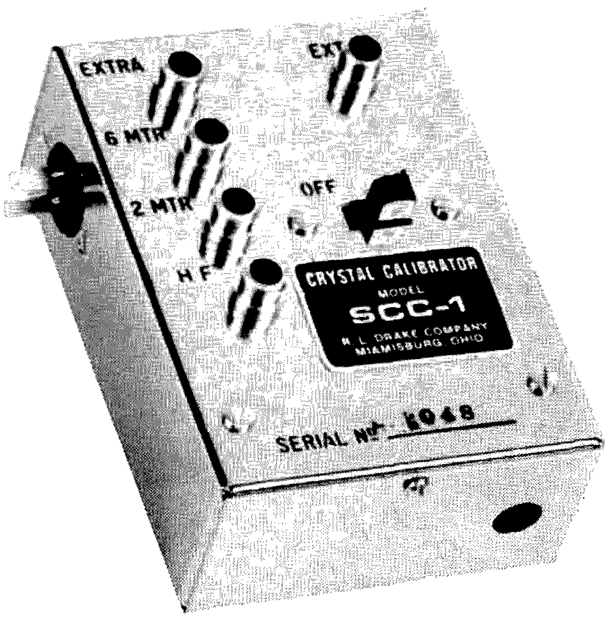
The two meter converter uses a TIS34 silicon, low noise FET in the front end. The mixer is also a TIS34 and follows a high pass filter to remove the mixer difference frequency.

The six meter model uses TIM12 germanium FETs. The noise level on 6 is higher than on 2, but this is to be expected and is certainly within tolerance for that band.

The *if* of both converters is 14 to 18 MHz and two crystals are provided for each unit giving fairly good coverage of each of the

bands. On 6 meters, 14.0-14.5 MHz gives coverage from 50.0-50.5 MHz with one crystal and 50.5-51.0 MHz with the other. On 2, coverage is 144-144.5 with one crystal and 145-145.5 MHz with the other.

For anyone wishing to change the factory alignment, the instruction manual gives fairly good details as well as a list of required equipment, but this can lead to sleepless nights, so unless you are prepared to spend a good deal of time, I would advise against making any changes. In the event you are brave enough to tackle realignment, and



make a bad job of it, Drake will realign it for five dollars plus postage.

The stability of both converters is superb. This is, of course partially dependent upon the stability of the receiver used. In my case, I used the Drake 2B. Interference from strong signals nearby are at a minimum and in some cases the selectivity is almost too sharp, especially on two meters. However, if you are interested in moonbounce or VHF DX work, this is a decided advantage.

The SCC-1 crystal calibrator is a jewel. It provides output for three converters and a separate receiver and gives accurate markings every 50 kHz to above 432 MHz. A trimmer is mounted in such a way that it is easily accessible, even when installed in the console cabinet. The oscillator is zener regulated and the circuit is a printed circuit with all parts easily accessible.

The CPS-1 power supply uses a full wave bridge rectifier mounted on a printed circuit board. The transformer has a fused primary and is mounted inside the case. The whole unit weighs only 17 ounces.

Both in performance, convenience, and good looks, this Drake package is tops.

. . . W1EMV

DX TEST

OK, you DX'ers, let's put it on the line. Let's see just how good you are at beam directions. All you have to do is guess the beam direction for the following countries within five degrees. If you live in Minnesota make that three degrees because you have an advantage over everyone else because we want not just the headings of each of these countries, but the headings that you would use if you were in Minneapolis. That shouldn't be too hard, right?

Credit your self with five points for each right answer.

Israel	......	Bermuda	......
Togo	......	Singapore	......
Burma	......	Iran	......

Turn to page 88 and see how well you know your beam headings.

About "Load"ing . . .

Which Loads What - or - What Does It Mean?

Presumably we all know what we mean when we talk about loading a transmitter, or an antenna being a good load–but we often run into some confusion when we attempt to communicate what we mean to each other. Not a small part of the resulting difficulty and confusion is due to the little-known fact that the word "load" has a multiplicity of meanings, some of which contradict each other.

Most of us automatically say, in such a discussion, that we are "loading the antenna," or that "the antenna won't load." Unfortunately a few of us purists feel that an antenna in itself is incapable of "loading" anything–it merely furnishes the "load" for the transmitter.

Discussion between editor, publisher, and a staff member over this point in regard to the License Study Course series led to some research, which in turn led to the discovery (which surprised us all) that for once, everybody was right.

Our authority is Funk & Wagnalls Standard Dictionary of the English Language, International Edition, a two-volume work which is not quite so complete as Webster's Unabridged, but more comprehensive than most for its size.

We found that the word "load" is descended to us from old English, which was the language spoken in England before about 1150 A.D. and includes Anglo-Saxon. Like most four-letter words of Anglo-Saxon origin, it has about as many meanings as it has users.

Specifically, our dictionary lists nine separate meanings for it if used as a noun, and twelve more if it is used as a verb. Of the twelve "verb" meanings, nine are "transitive" and three are "intransitive." This means merely that nine of the verb meanings require an "object" while the other three do not.

None of the twenty-one meanings listed are precisely the usage of ham radio, but several of them are close enough to our usage to draw some conclusions from. The first meaning listed for "load" as a noun is: "That which is laid upon anything for conveyance," and that corresponds pretty closely to our purist feelings that the antenna is the "load" for the transmitter – that is, when we connect the feedline we are "laying the antenna upon the transmitter." The fifth meaning as a noun is also fairly close to this viewpoint: "the resistance overcome by a motor or engine in driving machinery."

Had we stopped right here, the purists would have won a clear-cut victory, and we would have been forced to conclude that those of us who say "the antenna won't load" are wrong. But we didn't stop; we went on to examine the verb definitions too.

The first definition listed for "load" as a verb is a transitive usage, meaning that something must be loaded by something else. The definition reads: "to put something on or into to be carried," and that is a pretty close fit to our usage when we say that a transmitter refuses to load the antenna. It would, however, outlaw the phrase "the antenna refuses to load the transmitter" because the antenna does not put anything into the transmitter to be carried.

We kept reading, and came to the sixth verb definition (also transitive) which says: "to take on (a load, cargo, etc.)." This one fits precisely with those of us who feel that the antenna loads; when we say that an antenna "refuses to load," we are saying that it "refuses to take on" power.

The real clincher to it all, though, was verb definition ten, which reads: "to take on or put on a load or cargo." This one is blatantly two-way, and permits us to say either "the transmitter refuses to load" (meaning "the transmitter refuses to put on the load") or "the antenna refuses to load" (meaning "the antenna refuses to take on the load") while citing the same authority for either usage!

So what does it all mean? Simply this: everybody is right, despite the possibilities for unlimited confusion. When, in a discussion of loading, it appears that everyone is talking at cross-purposes, the thing to do is to bring the discussion to a halting screech and get everybody together with the *same* set of meanings at least for the duration of the discussion. Then you'll be able to make some headway with the real problems of *why* there's a loading problem, without staying hung up in the somewhat artificial problem of what *loading* actually means.

Ø Cycle Audio Filter For CW

A Short Circuit

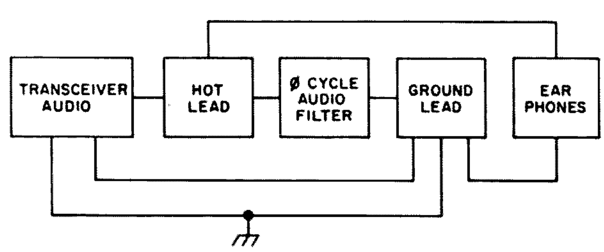
Sam McCluney, LX5SM/W4
910 John Anderson
Daytona Beach, Florida 32074

I am a bit of a CW addict, and at times my Galaxy leaves something to be desired, even with the 300 cycle filter turned on, in the way of selectivity. I felt I was really nitpicking if I was un-satisfied with such performance that I had achieved with no other work but signing the check. But such is striving for state of the art and I hoped to find some way of hearing only one signal and not many. With the BPD expedition in the offing, I felt that I should prepare myself for an even bigger onslaught of stations then I had to cope with when I was looking for WNV.

The narrowest filter I had seen advertised was a selectivity of 120 cycles. I of course had to try to beat this. So my goal was to be zero cycles selectivity, figuring that nothing could get through that in the way or QRM. All the filters I had seen were rather small in appearance. My own 300 cycle one was miniscule enough as was the 120 cycle one and a third that was advertised but I can't find at the moment. So along with outdoing the others in performance I had to outdo the others in size. This last wasn't hard to do for as every day passes there are more and more advances in microcircuitry, and all I had to do was use the advances that the others didn't have available when they were designing what turned out to be my competition. Lastly, if I could build it with parts I had on hand (read junkbox) then I could not only save money but also time in not having to go to the store for parts. Not really a requirement except in the most basic sense was the fact that I would need to be able to build a filter. Or I guess I should say figure out how to wire the parts together so they would achieve the desired resuit. I can use the term "design" now since it works but at the time I started I was "tinkering around with my stuff again." Working with audio, I didn't expect to have the problems I had when I tried to wire a six meter converter, though I am not putting down hi fi a bit. I guess I always will be a hay wire builder as well as I build. Well enough of this circut design parameter stuff and let me try to get into the theory of operation and then we will get down to the actual melting of solder which I call building.

Circuit Theory

After examining how the various audio filters worked I was impressed with the similarity of the circuits, as I am with transceiver circuits. Perhaps I am wrong but I felt if I was to achieve my hoped for performance of zero selectivity, then perhaps a different approach was called for. It seemed to me that maybe the maximum performance those circuts could produce had already been built and trying to achieve further narrowness was impossible. I think also secretly I wanted to do something different, cause I don't like to follow the crowd (except in DX) a prime reason why I was able to go through three years of the Army with a college degree and never rise above the rank of private. My mind settled on how best to eliminate all audio frequencies above zero. I was obsessed with the wonderful performance reports I had seen written up on Times Wire & Cable's new device which they called a "copper conducter." This had the remarkable fact that if it wasn't overloaded it would, at audio frequencies, shunt to ground all frequencies



Block diagram of Ø cycle filter installed in the audio system of receiver.

from zero to infinity, which seemed to meet my needs exactly. It turned out, upon experimenting with several prototypes in a breadboard circuit, that they were just exactly what I needed and my only problem was to choose the one I needed. This was quickly accomplished by choosing the smallest model that matched the audio power output (about 4 watts) of my transceiver.

Construction

I have always been a little bit annoyed with most construction articles, when they reached this point that they then said that if you couldn't follow a schematic then you weren't really a dyed in the wool constructor and they wouldn't tell you step by step how to build their pride and joy. I have been stopped many times from building what looked like a really good deal with just such an attitude of theirs. This is an excellent project for a beginner (my mother built one and her electronics goes only to operating the audio kill switch we have wired into the TV for commercials, and she got perfect performance in her model) as it doesn't take long to build and is very uncritical in wiring. I had the choice of wiring the modification into the receiver but that would mean lowering the resale value on the Galaxy on trade in time so that meant it had to be outboarded. The trouble with that though was that like the Galaxy filter it would be an extra box on the operating table and so at this stage I figured that if it could be wired into some other piece of equipment that wouldn't be traded, all the better. I finally settled upon the earphones themselves, since I had such small components to work with (thanks to microcircuitry) and large ears (thanks to genes). For a while I was going to modify both earpieces but decided against that, because of the extra work involved, so I make the modification in the earphone plug. The following step by step wiring diagram concerns that earphone plug modification, but the principle can be applied to just about any use.

1) Unscrew the plastic shell to the rear of the plug part of the plug.
2) Take a copper conductor and trim the leads to 1 1/8" when stretched straight.
3) Tin sparingly both leads of the copper conductor, use heat sink for protection. S2
4) Bend both leads so that they connect between the hot lead and the ground and make a good mechanical joint. NS
5) Place heat sink on lead extending from the copper conductor to the hot lead of the plug, apply soldering iron and solder. SI
6) Repeat step 5 for the remaining lead to the ground. SI

View of Ø Cycle Audio Filter installed in earphone plug. Note that the hot lead of the plug (top) is coupled to the ground lead of the plug via a Times Wire & Cable copper conductor. The plastic shell of the plug is to the left to show the wiring of the filter in the plug. The copper conductor and its leads are protected with a plastic covering. (VU2HG Photo)

Results

There, in six steps, are the secret to a whole change in CW operation. For me it has meant a whole new world, the complete absence of QRM; though with Gus set for take off in February (this is being typed 5 Dec.) I may still need something with even more selectivity. There is another advantage I think I have achieved with using a new circuit and components. That is, I have eliminated the annoying ring that comes with such narrow filters. The only trouble I have found now, seems to be receiver drift. Before, with 300 cycles, that was no problem but now with a 300% improvement in selectivity I find that I have to leave the transceiver on continuously and variac the line voltage to compensate for even one volt change in the line voltage. With my model 19, I find that I can copy on only one tone when they are on narrow shift and eliminate *all* errors, something that I haven't been able to do before on RTTY. Without a lot of fancy test equipment it is hard to say, but it is far better than anything I have ever read or heard about. The Galaxy filter has an audio amp to compensate for in-

sertion loss. This doesn't need one, so it apparently has no insertion loss. It is very convenient to use, for all I have to do for SSB is to unplug the headphone as usual and I am back at barndoor 2.1 kHz selectivity.

Finally, a note or two on construction hints (where I had trouble). I recommend that, for safety, the earphones be unplugged from the chassis as I attempted to wire the jack up without doing it and had a number of damaged copper conductors to show for the efforts. The other is to be certain of the polarity of the copper conductor so that the hot lead side goes to the hot lead side of the plug and the ground lead goes to the ground lead side of the plug. The two leads look the same, but are marked, so be sure to mark one lead with nail polish before taking it out of the box and risk getting them backwards. If you should get them mixed up, a simple resistance check with an ohm meter will straighten you out. As useful as these new copper conductors are, it won't be long before the price comes down and more people start manufacturing them. I expect to see a whole new series of articles in 73 using the devices that will come from what is now just in the embryo stages. . . . LX5SM/W4

Looking Back

Kayla, W1EMV

There seems to be a little Gremlin who plays havoc with articles and manages to build in errors. In some cases the errors originate with the author and the crew at 73, being overworked, lets them slip by. I guess the only way to have a magazine with absolutely no errors is to have more help, prepare each issue six months in advance and have 100 proof readers.

Here are some problems which have been called to our attention in recent issues.

August 1968, Pg. 70. A Review of the Newtronics 4-BTV.

Where reference is made to SWR at resonance, this is incorrectly printed as 1.5:1. It should be 1.05:1. The total height of the antenna is 23', not 33'.

October 1968, Pg. 30. High Performance Receiver for 2 Meters.

There are a couple of errors in the schematic on page 32. The primary center tap of T6 is not grounded. The resistor across L5 was shown with no value. This should be 47k. The oscillator tuning capacitor is shown as C4, but is called C1 in the text. Q5, which is numbered 2N385 on the diagram should be 2N3858.

November 1968, Pg. 20. IC Frequency Counter.

This article was oversimplified to a degree that most hams couldn't build it from the information supplied. We have since received voluminous material containing modifications, clarifications and corrections far too great to print for the limited number who will actually build this counter.

If you are seriously interested in building this counter, a SASE will bring you a copy of the additional material.

December 1968, Pg. 6. First Ham IC

In Fig. 4., page 8, there is no internal connection between the base of Q21 and collector of Q20. Since this article was printed, National Semiconductor Corp. has announced a lower cost version of the LM179/270. The new LM370 is now available through all NSC distributors.

January 1969, Pg. 28. Two Meter Transistor Transmitter.

The coil data was left out. Here it is:

L1- 18t # 24 el. ¼" slug tuned form, 2t sec. on coll. end
L2- 10t # 24 el. same as L1
L3- 6t # 18 bare ¼" dia.
L4- 2t same as L3
L5- same as L4
L6- 3t same as L5
L7- 4t same as L6
L8- 6t # 18 ½" dia. ct with 4t link
L9- Z235 with 6t removed
L10- 5t # 12 ½" dia. ct, 1t link

January 1969, Pg. 48. The Six Net.

Fig. 1. has several errors. In the lower left hand corner there should be a 500 pf capacitor in series with the crystal and the .01 capacitor which shunts the 560 ohm resistor. Without this capacitor, the oscillator will not oscillate. The 56k resistor at the base of TR2 does not go to ground. Rather, it should go to B-. The center tap of the output transformer does not connect to the junction of the two 10 ohm resistors. This creates a direct short. Instead, it goes to B-.

January 1969, Pg. 72. Quick and Easy QRP.

Figs. 1 & 2 were transposed in the text.

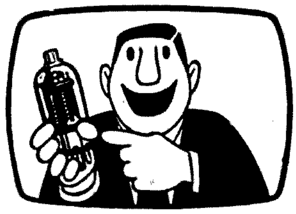
You can't win them all, but it would be nice to have a chance to win some of them.

Those Card Inserts

Several supposedly sophisticated readers wrote in to complain about the advertising card insert in the February issue. Perhaps they thought that I had suddenly changed and decided that I liked having cards stuck in 73. No, I hate it. But running a card like that makes it possible for us to print eight more pages of articles and this is hard to ignore.

If we charged you what it costs to put out 73, our subscription rate would be about $12 per year. The advertising in the magazine pays most of the freight and we are able to send you the magazine for three years for $12! Advertising is basic...the more ads the bigger the magazine...the fewer the ads the smaller the magazine. If you enjoy 73 and want to help, let our advertisers know that you appreciate their support of the magazine. And, let the advertisers who are not appearing in 73 know that you will support them if they support your favorite magazine.

— Wayne, W2NSD/1



NEW PRODUCTS

Pinpoint TV Troubles in 10 Minutes

If you are working with electronics gear this book is worth a few minutes of your time just to pick out the key ideas. And if you are in the TV service business it is probably worth much more than that to you. It explains and includes a carefully arranged, logical system for locating TV set faults.

The key point is that, for a given failure, some faults are more likely than others. An analysis of the observed symptoms will indicate certain circuits cannot be at fault, and that certain details might or must be out of line in some other circuits. For instance, if there is audio but no picture, you can scratch the low voltage supply and the front end circuits as sites for the trouble, and the high-voltage supply is worth early attention if a simple test indicates no picture tube voltage.

Pinpoint TV Troubles in 10 *Minutes is* TAB's book #428. It is available at your dealer's, or try TAB Books, Blue Ridge Summit, Pa. 17214.

New AF Generator

If your test gear uses vacuum tubes, it's out of date. Modern instruments using transistors and integrated circuits are more stable and reliable, use less power, and are very much smaller at no reduction in utility or accuracy.

A new audio generator has just appeared on the market. It meets or betters all specs for service type instruments. Imported from Japan by the DGP Company, it is probably going to revolutionize the whole test instrument market, which has not been very progressive lately.

About the size of a VOM, the generator weighs less than 2 lbs, and is about 7½" long, by 4" x 4". It has a calibrated vernier scale, and generates both sine and square waves (0.2 microsecond risetime!) over the range of 10 Hz to 100 kHz, at up to +9 dbm from a 600 ohm load. Amplitude and distortion specs are remarkably good, and the generator is useful anywhere 115-VAC is available.

The time is coming when a lab or service shop will have several little transistor and IC test gear boxes rather than shelf after shelf of big heavy contraptions for measurements applications. The early production runs of this generator are already sold but more are coming in, and are sure to be very popular in radio amateur applications. Price is $59.95.

Two Tips On Cutting Glass

Both of the following suggestions have been around for some time, but they do not seem to be general knowledge. In view of their usefulness, it would seem worthwhile to repeat them for the benefit of those who are not aware of them.

Chimneys for the 4 x 150 family of tubes are easily made by cutting off the tops of baby-food jars. To do the cutting painlessly, tie a heavy string around the jar about a ¼ inch below the point where you would like the break. Saturate the string with lighter fluid and set it afire. After the flame dies out, pick up the jar by the bottom, invert it, and plunge it quickly into cold water. The cut will be straight if the string was properly aligned and the jar vertical when it touched the water.

This works well on larger jars too. There are interesting possibilities in making chimneys for several of the larger types of tubes using peanut butter jars, etc.

Single strength sheet glass, such as is used in meters, dials, etc., is cut quite easily into odd shapes with tin snips or household shears. Fill a container, somewhat larger than the glass to be cut, with water. Immerse the glass and slowly cut out the desired shape. The glass must be entirely under water and the further the better. Be sure to wear gloves to protect your hands.

I know both of these ideas sound slightly unreasonable, but they work beautifully.

William P. Turner, WAØABI

BX Sheath is Handy!

The metal sheath used to enclose wires in BX electrical cable has many uses in the hamshack. The sheath can be used to cover several wires at a time. For example, a single BX sheath will enclose the coax and rotator cable leaving your shack for the tower. This reduces XYL resistance immensely! You can use BX sheath behind the operating bench to untangle the "wire jungle." As a bonus, the sheath looks really "professional."

You can get BX sheath at construction projects or from your electrical contractor. True, the lengths will not be more than a few feet long, but even this is enough to reduce a lot of "jungle" into only several cables. For long lengths of sheath, you will have to buy some BX cable and remove the wires inside.

You will be pleasantly surprised at how much neater your shack is when you use BX sheath!

D. E. Hausman, VE3BUE

(...de W2NSD/1 continued from page 2)

ate from if he is going to keep those dollars rolling in. This is where trouble has arisen in the past...once you are out on a small island somewhere who is to know where you really are? Or if you are sitting in some west African country who is to know for sure which one you are really operating from? It is a lot easier to sit back and drink a beer or coke for a couple of days and then come back on with a new call from a nearby country and save all the wear and tear on yourself.

Perhaps the new restrictions for DXCC will prevent this from happening again. I doubt it. When money is involved people find a way to get around just about anything. We've already seen false statements by ship captains in the recent past. It is possible that the ARRL will continue to accept fake DXpeditions rather than chance the members' anger by discounting them. I believe that they have enough evidence to write off some forty to fifty not too long past DX operations. I guess I don't blame them for choosing to hope that it will all blow over. Did you suspect that there might have been that many crooked operations in the last few years? Well, *you* paid for them. You keep donating money the way you have and you'll probably get more of the same. ... *Wayne*

CLUB SECRETARIES NOTE

Your club can round up some extra funds by imploring, cajoling, convincing, or forcing your members to subscribe to 73 Magazine. Never mind the cries of anguish, just remember that you are doing what is best for them—and the club.

Subscriptions to 73 are normally $6 per year. The special club rate is exactly the same: $6. The only difference is that the club treasury holds 25% of the loot and sends the rest to 73. Send us $4.50 for each one year subscription, in groups of at least five subs. Just think, if your club has 10,000 members you can quickly get $15,000 for the club on this deal!

Send the subscriptions to us on 3"x5" cards, giving the name, call, address, city, state and zip code of each subscriber. If the subscription is a renewal please include the address label from a recent 73 wrapper. Indicate all renewal subscriptions so we won't start a second sub. We have been known to do that.

Send to: Club Finagle, 73 Mag. PETERBOROUGH, N.H. 03458

Camp Albert Butler

Dorothy C. Saunders, W4UF
P. O. Box 295
Englewood, Florida 33533

For the ninth consecutive year, this past August saw men and women, and boys and girls, from all over the country arriving at Camp Albert Butler in the Blue Ridge Mountains of N.C. for its annual radio school. By plane, bus, and car they came, from all backgrounds and businesses, and ranging in age from 12 to 80.

This radio school, the only one of its kind in the country, is under the direction of Carl L. Peters, K4DNJ, General Secretary of the Gilvin Roth Y.M.C.A. in Elkin, N.C. It offers a maximum number of 60 students the chance to take a two-weeks' highly concentrated course leading to either the General, Advanced or Extra class of amateur radio license. On the last day an F.C.C. Examiner gives the students their examinations. Radio theory and code are taught in alternate courses during all of each morning, and again in the evening after dinner. Afternoons are free for study, code practice, swimming in the large outdoor pool, rifle, archery or pingpong. A number of field trips are also arranged during the two weeks to places of interest in the vicinity.

The camp is perched in a flat clearing on the top of one of the Blue Ridge Mountains, just two miles south of the Parkway, at about 3600' in altitude, with a striking view out over the great monadnock called Stone Mt., and miles of the rolling piedmont below. Rustic cottages are scattered among the large trees and rhododendrons, with the dining hall at one end of the swimming pool, and a very large recreation hall at the other. A camp radio station is in active use on several bands, as well as the sets brought by students, for skeds with home and other contacts during the session.

This was my second year as an instructor at the radio school and I had one of the mixed adult-teenager groups in radio theory, and the fastest code speed group, both leading to the general class of license. The general class students are divided into three theory and three code groups. On the first night of camp a code test is given to everyone, and separations into the code classes are made upon their ability to copy at around 5 wpm, or 8-9 wpm, or 12-13 wpm. The advanced and extra classes of students are together for both theory and code, with one instructor.

They worked hard to get their speed up to 13 wpm for their general class ticket, and to understand the intricacies of Ohm's law, and other problems of theory. For the adults, the financial successes of their past lives helped not a bit at the camp, where the only

criterion of success was whether or not one had passed the last theory test, or could as yet copy 65 consecutive letters without a mistake. The M.D.'s, judge, trial lawyer, retired executive vice president of one of the largest national food chains, priest, oil-well driller, oil-well owners, electronic components manufacturer, ex-h.s. principal, nurse, test driver for General Motors, policeman, engineers, and teenage grammar and high school students, among others, all studied and helped each other to understand difficult points, in a wonderful example of *esprit de corps* and friendship. One group of students, who might perhaps more correctly be dubbed "the young at heart" than "the young in years", were put together to live in one of the large cabins, which they promptly named "The Pill Box." They got along so famously that plans have been made to get together on a "Pill Box Net" as soon as they receive their licenses.

Highly motivated and bright as the teenagers are, it is a stimulating experience to teach them. It truly would be a revelation to some of their former teachers, I am sure, to see how hard they work. The teens are definitely the age when it is the easiest to learn code, as many an older student at camp ruefully realized when he struggled to copy 65 letters at around 13 wpm, and found next to him a 14-year-old breezing along with no effort and 100% correct copy. During the last several days of camp, the highest code classes for the General group are at 15 wpm, so that up to two minutes of speed may be lost through tension during the F.C.C. exam. Parents whose teenagers become interested enough in ham radio to want to study and get their general licenses, are indeed fortunate. There will be no delinquency problems in their homes, but instead fascinated youngsters at their little transmitters, learning to communicate with others of like interests elsewhere in the world, and slowly increasing their technical knowledge.

Once again this year on the morning of the last day of school, after a hearty and excellent breakfast, the instructors watched the long line of cars wind down the mountainside on its way to Elkin where the F.C.C. examinations were given.

Now little notes are being received by the instructors from their students, proudly giving their new calls and asking for skeds. And a new group of graduates of Camp Albert Butler is launched upon the amateur bands.

...W4UF

Getting Your Extra Class License

Part III Television and Interference

Staff

One of the most catastrophic factors ever to hit amateur radio was the advent, some 25 years ago, of television.

Old-timers may remember their problems with broadcast interference--but they were virtually insignificant when compared to the problems posed by TVI. Television interference just would not be tolerated by the public--and not a few incidents of violence such as toppling of antenna towers and pot-shots at the ham shcaks were recorded in the beginning.

Understandably, the FCC has rather strong feelings also about interference between the various services licensed by it, and so all examinations for Amateur licenses include some questions on television interference and its control. As the highest of all ham tickets, the Extra Class requires not only a knowledge of TVI control but also a knowledge of television techniques themselves.

We had originally intended to cover both TV and VHF in this installment of the Extra Class Study course, but it became obvious that if we combined the two we could do justice to neither. This month, then, we'll cover only three of the FCC study questions--those dealing with television. Next time, we'll move on to take our scheduled look at VHF.

This month's questions (the numbers, as always, are from the FCC list in case you're following it) are:

8. How does amateur TVI usually affect television reception?

34. Why are synchronizing pulses transmitted with television signals?

54. How can unwanted VHF resonances in a transmitter amplifier be moved from TV channel frequencies?

Following our usual practice in order to provide more comprehensive background, we'll rephrase these three questions into others.

All three require some knowledge of the actual transmission techniques used in television. Our first question, then, will be most broad--"What is Television?" From this beginning, let's find out "How Is Television Transmitted?" for the answers to the big problem, "How Is TVI Suppressed?"

Even if you're not interested in the Extra Class ticket, you may find this particular installment worth leafing through. While we'll be concentrating on the theory behind the practice, as we always do in this study course we'll also be touching on some most practical "how-to-do-it" points along the way.

Ready? Let's dive in!

What is Television? Some of you may find this question's implications insultingly simple --and others may find it to be far too complex. Lewis Carroll once wrote (if it wasn't he, it should have been): "The place to start anything is at the beginning", though, and that's why we're here.

Television is, of course, the picture on the boob tube; these days, as likely as not it's in glorious color. That's not really the answer we're looking for. What we actually want to know is, "How does it get there?"

Without going into the mechanism of the cameras at all--let's assume for now that they're working as intended--the picture gets on the face of the tube because it's *wiped* there by a speeding electron beam which actually *is* faster than a bullet.

This tiny beam is pulled across the face of the tube from left to right exactly 15,750 times every second, and at the same time it's pulled down the tube face from top to bottom so that it takes 1/60 second to make the vertical trip. During this single pass it covers the complete face of the tube, and draws 262-½ almost-horizontal lines as it goes. The beam then flies to the top of the tube--moving halfway across the tube face as it does so, so that the next pass begins in the middle of the horizontal line and draws another 262-½ lines. The timing is such that the lines almost but not quite overlap each other, so that a total of 525 lines are drawn every 1/30 second.

All the time that this little spot is moving on the tube face, its intensity is being changed

–and these changes in intensity are what put the picture on the screen.

In this entire process, everything happens with extreme speed. The beam must move the width of the screen in 1/15, 750th of a second, which on a "20-inch" tube works out to a horizontal motion of something like 14,000 miles per hour. The intensity must change in much less time than this, to reproduce the fine detail we're used to seeing. In fact, the intensity must be capable of changing in less than 250 *billionths* of a second in order for the signal to meet present federal standards.

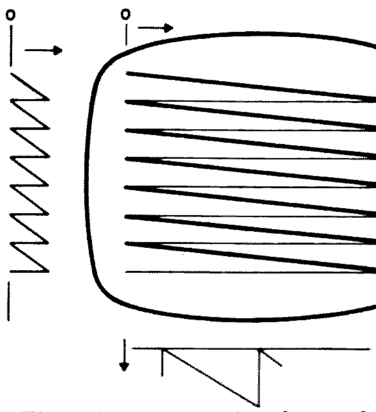


Fig. 1--The picture on the face of a TV tube is produced by the process shown here. A single electron beam is swept horizontally across the screen from left to right 15,750 times per second, and at the same time vertically from top to bottom 60 times per second. As it moves, its intensity is varried to produce the entire screen.

Fig. 1 illustrates the process we've been examining and shows how the electron beam paints the pattern of lines on which the picture appears. One complete pass of 525 lines is called a "frame", and the actual line pattern produced on the screen is known as a "raster".

At this stage, we still don't have a very clear image of how the picture gets on the tube–but we know that in order to get a picture there, we must control three items. These are: (1) the horizontal position of an electron beam, (2) the vertical position of that same beam, and (3) the beam's intensity.

The horizontal and vertical positioning of the beam in any TV receiver is done by "sweep circuits" which produce sawtooth waveforms at the appropriate frequencies. These waveforms are also shown in Fig. 1. The horizontal sweep waveform occurs 15,750 times per second, and the vertical waveform runs at a 60-per-second rate.

Both of these sweep signals are produced by free-running relaxation oscillators in order to generate as even motion as possible for the beam. Relaxation oscillators are notorious for frequency drift but are very easy to stabilize by locking or "synchronizing" them to some reference signal. The necessary reference signals in TV are the "sync pulses" which are transmitted as a part of the composite video signal; they yank the oscillators into step at the beginning of every sweep cycle. We'll get into this more a little later.

Intensity of the electron beam is controlled by varying the bias between grid and cathode of the picture tube; this bias is controlled by a wide-band ac signal known as the "video" signal. When bias is large (cathode positive or grid negative) the electron beam is weak and the screen is dark. When bias is less, the beam is stronger and the screen is brighter.

This action is identical with the amplification action of an ordinary audio amplifier tube, in which the audio signal controls grid bias and so changes the flow of plate current. The major difference is that in the TV picture tube the beam current is directly related to screen brightness and we don't have to have anything like a loudspeaker to convert current to sound or light. The only other significant difference is that the picture tube must handle a signal of much higher frequency than does an audio amplifier, since brightness in the picture may change several million times per second as the beam wipes across the scene.

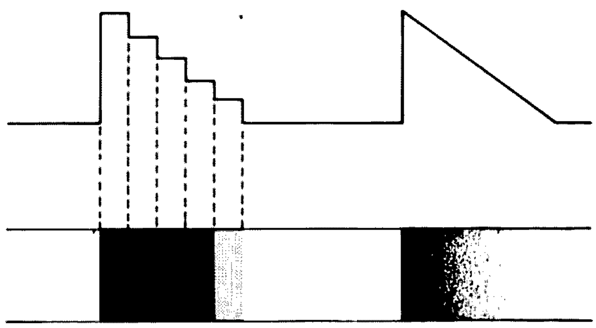

Fig. 2--This illustrates the relationship between the grid-cathode bias in the picture tube (upper waveforms) and the corresponding screen brightness on the tube's face (lower line). The greater the bias, the darker the screen. FCC regulations prescribe that the brightest part of an image must produce the lowest video voltage output, which cannot be less than 1/8 the maximum signal level, and that the darkest part of the image produce the maximum video level, which cannot be more than ¾ the maximum level. The portion of the signal above "black" level is used for blanking and sync pulses.

Fig. 2 shows the relation between picture-tube bias (or signal voltage on grid or cathode) and screen brightness. The upper line represents cathode voltage while the shaded band

represents screen brightness. The more positive the cathode, the darker the screen. As you can see, the signal may change either in stair-step fashion (left of figure) or continuously (right). The stair-step changes produce sudden changes of brightness while the continuous changes produce gradual shading effects. A typical picture will have both kinds of changes in it.

The TV camera also operates with a sweeping electron beam, which does the original translation of the picture into a varying electrical signal. For this varying-level signal to reproduce a recognizable image at the receiver, the receiver's sweep circuits must be locked exactly to those of the camera. This is the primary reason why the sync pulses are included in the composite video signal.

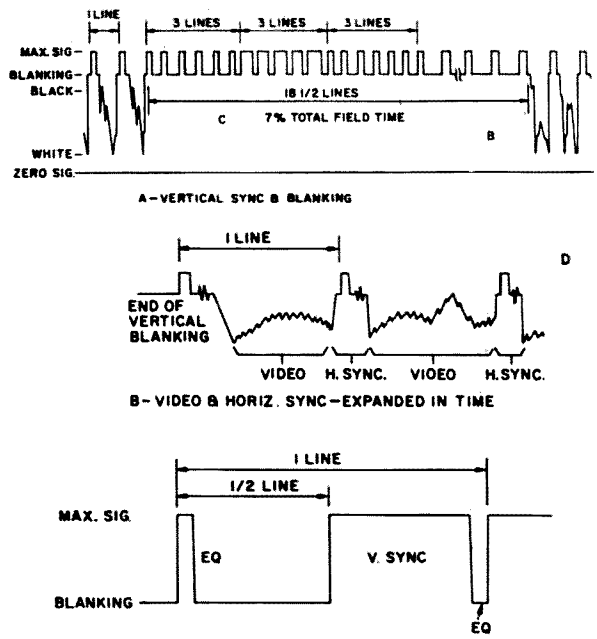
We've talked about the "composite video" signal several times now without explaining it at all. It's not the same as the "video" signal. The "video" signal consists *only* of the voltage changes representing brightness variations. In commercial broadcast TV, bandwidth of the video signal is set at 4.5 MHz; in industrial and closed-circuit TV, bandwidths as high as 6 MHz are frequent. The low-frequency limit on this signal is only a few cycles per second; it must be able to hold the screen dark for several frames at a time. In fact, for highest quality, this signal should extend all the way down to dc at the low end–but for economy's sake, it seldom does.

To keep the video signal from the camera in step with the receiver's sweep circuits. sync pulses in both the horizontal and vertical directions are necessary. When these pulses are combined with the video signal, the result is the composite video signal. **Fig. 3** shows the waveforms involved in a black-and white broadcast TV composite video signal.

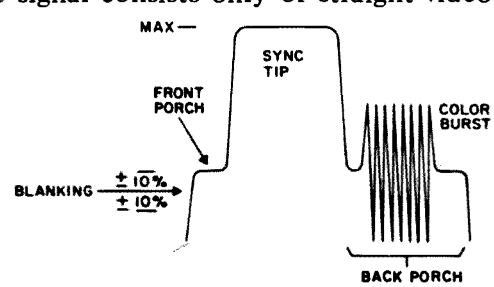
Before we examine **Fig. 3** in any detail, let's move on a little bit and look at color. Color TV is almost exactly like black-and-white so far as the transmitted signals are concerned, although the actual equipment and circuits are far more complex for color.

The big difference with color is that we must control a fourth factor in addition to the two positioning signals and the beam intensity (which is known as the "luminance" signal in color TV). This fourth factor is the signal which determines the exact color mix produced by the beam at any one position, and it's called the "chrominance" signal.

We won't go into much detail about the chrominance signal except to say that it's carried on a phase-modulated subcarrier signal. The only reason for looking at it at all, at this point, is because in a color TV composite video signal we have all the elements of the black-and-white signal–*plus* an 8-cycle "reference burst" to let us work with the chrominance signal. This reference burst is also shown in **Fig. 3**. It is transmitted *only* in a color signal, and is not present when black-and-white is being transmitted.



Now, let's look at **Fig. 3** in detail. You can see that four separate views are necessary to show the complete makeup of the composite video signal. The most general, view A, shows the vertical sync pulse and "vertical blanking interval". This set of waveforms shows up 60 times every second; the rest of the time the signal consists only of straight video over-



D–H. SYNC DETAIL

Fig. 3--These four views at different degrees of expansion in both time and signal amplitude show the details of the synchronization pulses, equalizing pulses, and color burst on the FCC standard television signals. View A shows the major portion of the vertical blanking interval while views B and C expand portions of view A. View D details the tops of the horizontal sync pulses to show front and back porches and the color burst. Color burst is omitted from B&W telecasts.

laid with the horizontal sync pulses as shown on either side of the vertical blanking interval in view A.

As view A shows, the vertical blanking interval takes up 7/100 of the time for each complete field (a field is 262-½ lines, or half of a frame) and occupies the same time as 18-½ lines. In TV, incidentally, it turns out to be convenient to refer to time in terms of "lines" since the duration of one line is a key time, to which everything else in the signal must be related.

Of the 18-½ lines occupied by the vertical blanking interval, only 3 lines are occupied by sync pulses themselves. Six "equalizing pulses" occur on either side of the vertical sync pulses, and the spaces between vertical sync pulses are also employed as equalizing pulses. During this time, no horizontal sync signals are present and the equalizing pulses are used instead.

The other important point contained in view A is that all of the sync information is transmitted at a level higher than the blackest black in the picture, which in turn is higher than any lighter shades. The technician's term for this is to say that sync is "blacker than black". Maximum and minimum levels for each part of the composite signal, with reference to the maximum radiated level, are set by FCC regulations. The blackest part of the picture cannot produce a level higher than 95 percent of the "blanking level", and the blanking level itself cannot be higher than 85 percent of the maximum signal.

As a result of these restrictions, the transmitted picture is enclosed in a blacker-than-black frame produced at either side by the horizontal blanking and at top and bottom by the vertical blanking interval. More important to the viewer, the sweeping electron beam flies back across the picture during these times. Having its intensity turned all the way off makes circuitry much simpler.

You can see these signals on any TV set, incidentally. All you need do is turn the brightness up and contrast down so that "black" becomes a middle gray, and carefully adjust the vertical hold control until a black bar rolls slowly down the screen. In the center of this dark bar you will be able to see a darker area with a shape in the middle faintly resembling the head of a sledgehammer.

If you are steady enough of hand to adjust the dark bar to a stationary position in mid-screen, you can count the lines in it. You will find that the darker area in the center is composed of the vertical sync pulses, with 3

lines above it and 12-1/2 below. You may count 6 and 25 respectively, if your set is in excellent adjustment, due to the interlacing of successive fields into frames.

View A in **Fig. 3.** also indicates the parts of the signal to which views **B** and **C** apply.

View **B** shows two lines of video immediately after the vertical blanking interval, and their two associated horizontal sync pulses.

View **C** shows the relationship between equalizing pulses and vertical sync pulses. The equalizing pulses keep the horizontal sweep in sync during vertical-sync times, and also permit the half and half interlace since they occur twice as often as horizontal sync pulses.

View **D** shows the top of a horizontal sync pulse. The part which protrudes upward is known as a "sync tip" and performs the actual synchronization. The part which is at blanking level immediately preceding the sync tip is called the "front porch" while that immediately after the sync tip is the "back porch".

Also shown in View **D** is the color reference burst, which occurs on the back porch if it is present. This signal, which is absent in black-and-white signals, consists of at least eight full cycles of a 3,579,545 Hz sine wave, accurate in frequency to within 10 Hz. This signal is produced at the transmitter by a continuously-running oscillator and is keyed into the composite video without any change of phase. Its modulation limits are approximately equal to the height of the sync tips.

Now that we know more than we really wanted to about the nature of the composite video signal, we can see how it is used in a TV receiver.

The entire signal is received by the front end just like any other VHF signal, and goes through mixing and the *if* strip. An ordinary diode detector then recovers the composite video from the *if* amplifier output. The composite video is then amplified to a level adequate to swing the picture-tube beam from full on to full off.

The sync signals are applied to the picture tube also, where they blank off any output during retrace times. At the output of the video amplifier, they are also picked off by a sync separator circuit which is essentially a pair of low-pass filters. One filters out everything but the relatively low-frequency vertical pulses while the other takes out the video but lets both horizontal and vertical sync remain.

The signal containing both horizontal and vertical sync is then passed through a clipper which lets *only* the sync tips through, so that nothing comes out from the vertical pulses while one blip emerges for each horizontal pulse that comes in.

The resulting vertical and horizontal sync pulses are then applied to the sweep circuits where they lock the oscillators in step with the transmitted signal. Each sweep circuit contains amplifiers which drive the yoke and deflect the electron beam. The horizontal output circuit also is used to develop the high voltage for the picture tube, since horizontal sweep is always present.

As the sweep circuits wipe the beam across the face of the picture tube, the video signal varies its intensity, and the result is a reproduction in light and darkness of the image being viewed by the camera.

Strictly speaking, this answers our original question "What Is TV?"–at least in an oversimplified version. But all that we have looked at so far is the sending and reception of the video information. When most of us think of TV, we think of the whole thing–both picture and sound and maybe even the color.

We don't go into the mechanics of color very far, because it's full of abstruse mathematics. Commercial TV, though, we can explore in more practical detail. In fact, we must if we are going to use our results in battling TVI!

Even at this state, it's fairly easy to see that any ham signal which gets mixed into the broadcast video signal is going to be displayed on the TV screen as a pattern of light and shadow. The exact pattern displayed will depend upon the ham signal itself, since the unimaginative receiver can't tell the difference between one of our AM voice signals and the also-AM video signal it's designed to receive and display.

But the composite video signal is not the only one present in a TV channel. We've already made in passing the acquaintance of the "chrominance" subcarrier–which just happens to lie in the 75-meter phone band, and *can* get clobbered in some cases by a ham signal. The result is wild to see–the picture is fine except that all the colors are wrong, and they shift with the modulation of the interfering signal. Lovers of the psychedelic should view it sometime; they might find it more entrancing than acid.

Also present in each channel, though, is an audio carrier. Audio in this country is FM, and so hams seldom interfere with it. *Fig. 4* shows

the various signals within a TV channel, their frequencies with respect to the low-frequency end of the channel, and the relative strength of their outputs.

In this country, VHF TV is broadcast on 12 channels numbered 2 through 13, and UHF TV occupies the 70 channels from 14 through 83. The VHF group is divided into "low band" and "high band" regions. Low band runs from 54 to 88 Mc, with a 4-MHz hole between 72 and 76 MHz (between channels 4 and 5); high band runs from 174 to 216 MHz continuously. *Fig. 5* lists the 82 channels and their frequency limits. To determine the exact frequency of any specific TV signal you can use *Fig. 4* and *5.* together *Fig. 5* provides the channel limits, while *Fig. 4* shows the position of each signal within the channel.

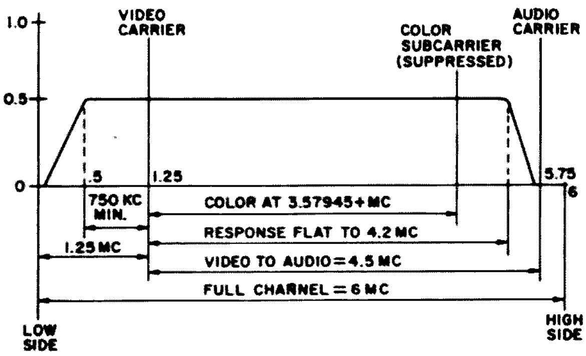


Fig. 4--Arrangement of signals within each of the 82 commercial and educational TV broadcast channels is as shown here. The video carrier, located 1.25 MHz above the low limit of the channel, is the reference for all other signals. The audio carrien is exactly 4.5 MHz higher, and the color subcarrier if present is 3.579545+ MHz above the video. Response must be flat from 750 kHz below the video carrier to 4.2 MHz above, and taper off rapidly beyond these limits to zero at the low channel edge and at the audio carrier. Limiting frequencies for each of the channels are tabulated in Figure 5.

In some cases, signals within a channel may be offset by 10 kHz either side of those shown in *Fig. 4.* If an offset is present for any TV transmitter,it will be the same amount and in the same direction for all signals from that transmitter. The purpose of this offset is to reduce co-channel interference between two stations assigned the same channel; with one of them offset 10 kHz high and the other offset 10 kHz low, their signals will always be 20 kHz apart--and this is enough to reduce interference significantly.

Broadcast TV modulates the video carrier with AM, using a technique called "vestigial sideband". This is partway between ordinary AM and SSB--but the carrier is not suppressed. All of one sideband is transmitted, but only

CHANNEL	BAND	CHANNEL	BAND	CHANNEL	BAND

Figure 5--Broadcast TV channel limits in MHz. Horizontal lines separate listing into low-band VHF, high-band VHF, and UHF channels. See Figure 4 for exact frequencies of various signals within channel.

a part of the lower sideband is sent. This is the portion closest to the carrier, which is carrying the low-frequency components of the video signal.

Any other signal near the video carrier may beat with it to produce sidebands within the video-sideband range. The effect on the screen ranges from horizontal black bars, if the beat frequency is low, to a grainy cross-hatched appearance if the beat frequency is higher than the horizontal sweep frequency of 15.75 kHz. If the interfering signal is also AM, its modulation will also interfere; this always produces the horizontal-bar effect since the modulating frequencies for speech are below 15 kHz. These bars flicker with the modulation, and are usually called "modulation bars" or "sound bars". They may be produced in the TV receiver even without interference, by mistuning the set so that the FM audio is slope-detected in the video circuits and applied to the picture tube.

If the interfering signal is FM, its modulation will not usually be apparent on the screen. The usual result of FM interference is a shifting cross-hatch pattern, which moves with the modulation. This is much less annoying to viewers than are the big black bars--which is one of the major arguments in favor of FM for VHF operation in metropolitan areas.

But we're getting ahead of our questions Now that we have an admittedly oversimplified idea of the basic principles of TV as used in this country today, let's move on.

How Is Television Transmitted?

We've already met the various components of the transmitted TV signal--the video, the sync components, the color burst if any, and the audio--and we've taken a look at the channel assignments. We've also taken a brief trip through the typical TV receiver. Now let's go through a typical TV transmitter in the same way.

The starting point can be the TV camera itself. Like the picture tube of the receiver,

the camera has a screen and sweeps an electron beam across this screen by means of horizontal and vertical sweep signals. However, in the camera the electron beam current is originally steady as it travels from cathode to screen, and is made to vary by the brightness of the image which is focused upon the screen. This is the exact reverse of the process in the receiver, where the beam current varies and these changes of current are transformed into changes of screen brightness.

The mechanics of how image brightness makes the beam current in the camera change vary from one type of camera tube to another; some typical camera tubes are the bidicon, the image orthicon, the iconoscope, and the plumbicon. All, however, produce a video output signal which is determined by the brightness of the single spot on the screen which the beam is resting upon at any instant in the scan.

In a color TV camera, things are more complex; three camera tubes are used; and the image reaching each is filtered so that it contains only one of the three primary colors. The resulting three video output signals show how intense each of the colors is at the particular spot in question. These three signals are then combined into a single "l u m i n a n c e" signal which indicates total brightness of the spot, and also into a complicated "color signal" which indicates the red, blue, and green content at that spot. The luminance signal corresponds to the single "video" signal of a black-and-white transmitter. We'll ignore the "color signal" for a while.

The video carrier of the TV transmitter is generated in the same manner as any VHF or UHF signal; a stable crystal oscillator produces an original signal which is frequency-multiplied until the desired output frequency is obtained. Normal rf-amplifier techniques are used between the oscillator and the modulated amplifier.

The extreme bandwidth involved in the composite video signal makes plate modulation impractical for TV, and the difficulties of getting large amounts of power into a video signal of such bandwidth also tend to rule out high-level modulation of any type.

As a result, general TV practice is to grid-modulate at relatively low power levels so that the minimum of video power is required, and employ linear amplifiers to boost the transmitter power to the desired level. For ham TV, the linears are not necessary, since the modulation is usually applied to a stage producing from 100 to 400 watts output.

The vestigial-sideband response shown in *Fig. 4* is obtained by tuning the linear amplifiers to the center of the channel rather than to the video carrier frequency. Often, additional filtering is added in the antenna transmission line to reduce the out-of-channel energy remaining in the lower sideband.

Between the video output from the camera, and the modulator which adds the video information to the rf carrier, the sync information is added to produce the composite video signal. *Fig. 6* shows in some detail the nature of the transmitter sync-signal generation.

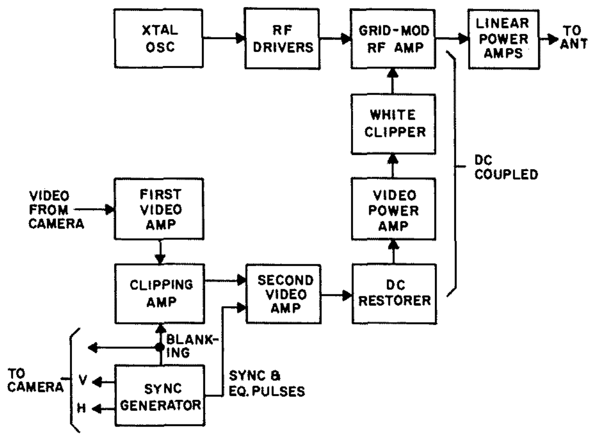

Fig. 6--This simplified block diagram of a black-and-white television transmitter shows how sync and blanking pulses are inserted into the composite video signal ahead of the modulator. Except for these stages, transmitter is functionally identical to any radio transmitter.

The original pulses are produced by a "sync generator", which is usually locked to the ac power-line frequency (both sweep frequencies are integral multiples of 60 hz. In color TV, the sync generator is locked to the color subcarrier oscillator rather than to the power line, and the sweep frequencies are very slightly different.

The sync generator provides pusles to control the sweep circuits in the camera itself, and also produces blanking pulses to the camera and clipper, and sync and equalizing pulses to the second video amplifier.

The blanking pulses kill video output during the vertical and horizontal blanking intervals and thus make space available in the signal for the sync pulses. The clipper cuts off the tops of the blanking pulses at a level just barely "blacker than black". "Black" is a video level which is 75% of the maximum composite-video signal voltage, and the blanking pulses are clipped at approximately 85% of maximum-output level. This assures that the tops of the blanking pulses are free of noise or hum.

The second video amplifier then inserts the sync and equalizing pusles into the signal to produce an almost-complete composite video signal. However, the blanking level of the signal at this stage would vary from a bright picture to a dark one as shown in *Fig. 7*; the restorer between the second video amplifier and the power video stage clamps the composite video signal to maximum output level rather than to the zero output level as shown. From this point on through the modulator itself, the signal is always dc-coupled to preserve the blanking pulses always at the same level as required by FCC regulations. The "white clipper" between the final video stage and the modulator prevents the negative peaks of the composite signal (which represent the white parts of the image) from dropping below 1/8 the maximum-output voltage.

While this completes our examination of the video transmitter, we still have more to see--because there is audio to be considered as well, not to mention the antenna itself and the special considerations of color. The audio signal from a TV station in this country is produced by a completely separate transmitter.

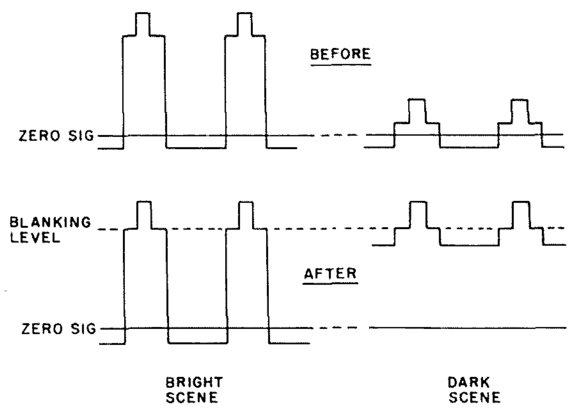

Fig. 7--DC Restorer circuit and subsequent DC coupling of signal is required to hold constant blanking level as shown here. Before DC restoration (top), entire signal shifts in level with brightness of scene. After restoration (bottom) blanking level remains constant and dark scene level is pulled up to correspond to that of bright scene. Many top quality receivers also incorporate DC restoration to preserve proper brightness ratio to final image; lesser-quality sets often omit the circuit and contrast of image varies with scene's brightness. Bright scenes have high contrast but dark scenes become grayish and contrast is dulled.

This transmitter is an ordinary FM unit; the only special points about it are that its frequency is exactly 4.5 MHz higher than that of the video carrier, and its swing is limited to a maximum of 40 kHz either way (25 kHz normal for 100-percent modulation). Also, transmitter output power cannot be great-

er than 70 percent of video transmitter power.

The audio and video carriers, though generated by totally separate transmitters, are radiated by the same antenna system, and that's where they are combined into a single channel.

TV broadcasting in this country is required by law to use horizontal polarization; turnstile arrays and variants of them are common. Normally the arrays are set up to compress the beamwidth in the vertical plane, and give omnidirectional coverage in the horizontal plane. A turnstile antenna does this by using two sets of radiating elements, one for east-west coverage and the other to cover in the south.

north-south direction. The two are fed 90 degrees out of phase.

The audio and video transmitter outputs are connected to the antenna array by a diplexer arrangement such as that shown in *Fig. 8.* This arrangement does *not* include the

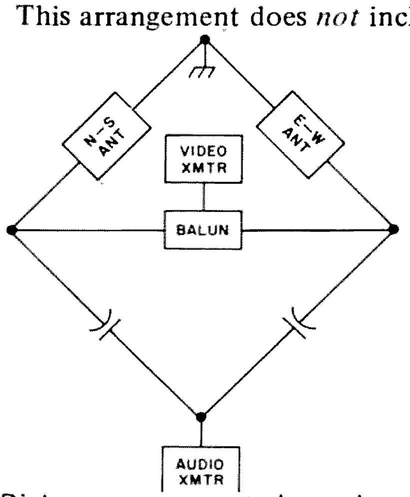

Fig. 8--Diplexer arrangement shown here is used to couple both audio and video transmitters to turnstile antenna array while isolating each transmitter from the other. Similarity to Wheatstone bridge circuit is emphasized in this drawing; isolation is produced by the balanced-bridge principle.

phase shift necessary for operation of the turnstile antennas; its purpose is to permit all the output of each transmitter to flow to the antennas, without any of the output of one transmitter being routed to the output circuit of the other transmitter. The similarity to a Wheatstone bridge circuit is apparent, and it functions in exactly the same manner to isolate the transmitters from each other.

All the way through, this installment, we've been putting off any detailed look at the way color TV works. We can't do so any longer. Now that we have a fairly complete idea how black-and-white TV operates, it's time to throw caution to the winds and look at color.

Before we get into the special requirements, though, we must pause a few moments and look at the whole idea of "color" itself.

"Color" is a characteristic of light, and light is simply electro magnetic energy of fantastically high frequency but otherwise identical to radio waves. The color of light *is* its wavelength (or frequency, of course) and what we know as "white" light is actually a mixture of all the possible colors of light which our eyes can perceive.

Most objects have no light of their own; we see them because they reflect light from other sources. The color of light which is reflected is not necessarily the same as the color of all the light which falls on the object–but (in most cases) the light reflected *is* of the same color as at least a part of the light which falls on the object.

For instance, lips reflect red light during the daytime; the sun's light contains plenty of red to be reflected. But at night under high-intensity "whiteway" lights, which are rich in blue but have almost no red at all, lips appear black. There's no red to reflect, and the blue isn't reflected.

What actually happens to produce color in any object which has no light of its own is that all the light of any *other* color is absorbed from any light which happens to arrive; all that *can* be reflected is whatever happens to be left.

Thus a leaf is green because it absorbs the light of any color *except* green, which leaves only the green light for us to see it by.

If the light falling on anything happens to have only one color in it, then anything which absorbs that color will appear to be black or at least dark gray, and anything which does not absorb that color will be light.

Most of us were taught in primary school art classes that any color we want can be obtained by mixing the three "primary" colors red, blue, and yellow. What most of us were *not* taught at that same time was that the same effect could be obtained by mixing the three "primary" colors of light rather than paint–and that the primaries for light were slightly different than those of paints!

When mixing paints, the primaries are magenta (almost red), cyan (between blue and green), and yellow. Magenta removes the green from any light which falls upon it; cyan removes the red; yellow removes the blue. When we mix light, the primaries are green, red, and blue.

We can prove this with three spotlights and a set of red, blue, and green filters. With one filter on each spotlight we can aim them to produce overlapping circles. Where all three of the light primaries are present, we get white. Where red and green are mixed but blue is absent, we get yellow. Where red and blue mix but green is absent, we get magenta. And where blue and green mix in the absence of red, we have cyan. The effect is similar to that shown in *Fig. 9*. The color sequence around the ring of white light in the middle runs from blue through cyan through green through yellow through red to magenta.

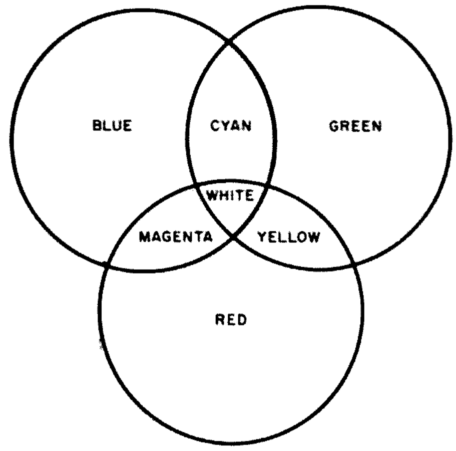

Fig. 9–Generation of color by mixing colored light from three primary sources of blue, green, and red is indicated here. This differs from the traditional production of color because in this case colored light is used rather than colored paints or inks. The color in color TV is generated by mixture of these same three primary colors.

Exactly the same sequence of colors is produced if we mix cyan, yellow, and magenta paints; where the yellow and magenta are mixed, the yellow removes any blue from incoming light while the magenta removes any green. The only light primary left to be reflected is red. Similarly, where cyan and yellow are mixed the cyan removes any red and yellow removes any blue; what's left is green.

Now back to color TV. The picture we see on the screen of a color TV set is produced by a sweeping spot–which is actually a *source* of light. This means that the primary colors we'll be using in color TV are the light primaries, red-blue-green, rather than the paint primaries you're more likely to be familiar with. In case of confusion, it may help to remember that one is the other turned inside out–and it may not!

We have already noted that in the color TV camera, three video signals are produced, one for each of the primary colors. Each of these

signals tells how much of its color is present in a particular part of the image at a given instant.

The three original signals, E_b E_r and E_g, are combined into three new signals. Each of the new signals is a combination of all three of the originals, but the rules by which they are combined differ for each of the new ones.

One of the new signals is combined by a rule which takes into account the relative brightness of each of the original colors. "White" light is 59 percent green, 30 percent red, and 11 percent blue, and so the original green signal contributes 59 percent of this new signal while the original red puts in 30 percent and the blue makes up the remaining 11 percent.

This new signal, sometimes called E_Y but as the luminance signal, carries *all* of the brightness information for the picture. It corresponds exactly to the single video signal of black-and-white and goes through all the same steps.

The two remaining new signals are combined by other rules. If you're really interested in the precise rules for them, and are ready to read several pages of trigonometric equations to learn them, you can find them starting at page 1000 of the fourth edition of *Electronic and Radio Engineering* by F. E. Terman. The important thing, for our purpose, is that the rules produce a pair of signals which tells us how far, and in what direction, the color at that spot in the picture is from a neutral gray tone. These signals are known as the chrominance signals; one is the I signal and the other the Q, for "in phase" and "quadrature".

Both of these signals originally occupy the same bandwidth as does the luminance signal--from 60 hz to above 4.3 MHz--but they are filtered to narrower limits because the eye doesn't sense small changes of color. The I signal is limited to a 1600 kHz band width, and the Q signal is cut down to 600 kHz, without visible loss of detail.

The Q signal is then DSB-modulated on the color subcarrier. The I signal is also DSB-modulated on the same subcarrier after a 90-degree shift in subcarrier phase. The subcarrier is suppressed from both signals, and the I-signal output is filtered to remove that portion of its lower sideband below 600 kHz. Finally, both the I and Q output signals are put together; the resulting single chrominance signal has no carrier, double sidebands for modulating frequencies below 600 kHz, and a single sideband for modulating frequencies

Make Your Own Professional Name Plates

The last word in putting the final 'polish' on a piece of home-brew gear is to provide it with a professional appearing name plate. Applying decals directly to the panel is more often used, but this method makes such lettering appear more like one of the many individual component labels.

To make a name plate which will stand out and serve to identify the unit as a whole, is a simple matter. Apply the small decal letters, preferably of the dry transfer type such as the Ami-Cals, to a small piece of scrap bakelite or a piece of polished metal, if you prefer. Drill two mounting holes and attach the finished plate to the equipment panel with small sheet metal or machine screws.

The accompanying photograph illustrates how the author labelled a recent project using a piece of scrap bakelite 1/16 inch thick, cutting to size and bevelling the edges with a file. Try it on your next project; You'll be surprised what a 'professional' touch it will add to a piece of home-brew gear!

Howard S. Pyle; W7OE

above 600 kHz and below 1600 kHz.

This combined chrominance signal is applied to the transmitter's second video amplifier, just as are the sync and blanking pulses. At the same time, the color burst (taken directly from the subcarrier oscillator) is put onto the back porch of each horizontal blanking pulse. The complete color composit video signal is then transmitted just as is a black-and-white signal.

While both I and Q signals are present throughout the video channel, they have little effect upon the picture itself because the color subcarrier is an *odd* multiple of half the line frequency. This means that any effect of an I or Q sideband upon the electron beam during one sweep of a picture line will be cancelled out by an opposite effect on the next sweep of that same line. The only effect which is not cancelled is a 15 Hz flicker in areas of small, fine detail. You may see this from time to time on your TV screen; it affects both color and B&W sets whenever color is being transmitted and fine detail such as checked fabric appears in the picture.

At the receiver, the I and Q combined chrominance signal is picked off by appropriate filters and applied to a pair of synchronous detectors which are very similar to those used for reception of ham DSB signals. The major difference is that in ham DSB, we must get the carrier back from information contained in the sidebands themselves, and in color TV, the color subcarrier frequency is sent to us in the color bursts which occur at the end of every line.

The outputs of the two synchronous detectors are again filtered to remove the Q signals from the I channel and vice versa. Then the I, Q, and Y signals are applied to three circuits which combine them in an exact reversal of the rules by which they were originally produced at the transmitter. These circuits produce as their outputs replicas of the original red, green, and blue video signals.

Each of these three primary-color signals is amplified separately and applied to the corresponding electron gun of the color picture tube. The result is glowing color on the screen.

For this process to work right, the I and Q signals must bear the same relationship to each other and to the Y signal at the receiver that they did at the transmitter. However, transmission-path differences can disturb this relationship, and additionally the differences from camera to camera at the transmitter can introduce additional disturbance. All these disturbances can be corrected by fine adjustment of the phase relationships in the synchronous detectros; this is the function of the "hue" control on color TV receivers.

How Does Television Interference Occur? Television interference falls into three main classes, each of which occurs for different reasons. The three major classes are (1) TV receiver overloading by the interfering signal, (2) interference, either audio or video, by spurious emissions, and (3) interference by harmonics of the interfering signal. A fourth class consists of interference created by uncontrollable cross-modulation.

Overloading of the receiver normally occurs only if the TV receiver is located within a few hundred feet of the transmitter causing the interference. It is caused by the transmitted signal getting into the TV circuits--either on the antenna line, via the power line, or by direct pickup through the TV cabinet--and overloading some critical circuit. It may easily be recognized by the fact that it is present on all channels in equal degree, and almost invariably disappears if the transmitter is operated into a dummy load rather than into its antenna.

Interference by spurious emissions includes such things as overmodulation splatter, key clicks, and parasitics. At the TV set, this type of interference may resemble that caused by harmonics, but is likely to be much more intermittent.

Harmonic interference is the most common form of TVI and may usually be identified by the fact that it affects different TV channels differently. However, if the harmonic happens to fall at the IF frequency of the TV set, it may affect all channels equally. This rarely occurs since most modern TV's incorporate filtering to prevent signals at the *if* from getting past the first few stages.

Uncontrollable cross-modulation is an interfering signal produced by some non-linear element not under the control of either the amateur or the TV set owner--such as oxidized guy wires on a power pole, or a rusted gutter on the neighbor's roof. When two strong signals reach such a non-linear element, they may mix just as they would in the mixer stage of a receiver to produce sum and difference frequencies. If one of these difference frequencies falls in a TV channel, it will be an interfering signal for that channel.

Interference of this type is called a "phantom" signal; its identifying characteristic is its extreme randomness, since both the strong

signals must be present for it to be produced. If either transmitter goes off the air, the phantom disappears. When the phantom is present, however, the modulation of both the original signals may be present on it and capable of being understood--so the TV set owner may be completely convinced that the ham is at fault.

Fortunately, this type of interference is rare enough that you may never experience it--because when you do, only a painstaking search for several miles around can locate the offending non-linear element. Frequently it's easier to merely avoid use of the particular frequency which results in a troublesome phantom!

Most TVI is due to harmonic radiation; good design of the amateur transmitter, coupled with good operating practice, can hold the problem to a minimum--but any transmitter *must* radiate at least some harmonic energy, because of the way in which an amplifier works. The object of harmonic chasing when battling TVI is to reduce these harmonics to such a low level that they will not be troublesome.

We've already looked at the frequencies allotted to television in this country, and the use made of the space within each channel. *Fig. 10* relates the TV channel assignments to the various harmonics of the popular ham bands.

The exact effect of harmonic interference depends upon both the exact frequency of the harmonic, and the type of modulation employed. If the harmonic is within a TV channel, it will form a beat frequency with both the video and the audio carriers. If either beat frequency is below 15,750 hz, horizontal bars will be produced on the screen. If the beat is above the horizontal sweep frequency, vertical bars will result. As the beat frequency moves around 15,750 Hz, the bars rotate from horizontal to vertical, and produce a cross-hatch pattern on the screen.

An unmodulated carrier (or harmonic) normally produces only a steady cross-hatch pattern. A frequency-modulated signal produces a cross-hatch which appears to rotate with the modulation. CW turns the cross-hatch on and off. AM, however, produces modulation bars which we have already met.

An amateur FM signal may, if its harmonic

Fundamental	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
3.5 to 4.0 MHz				NONE					
7.0 7.3					TV IF		TV 2	TV 3	TV 4
14.0 14.4		TV IF	TV 2	TV 4	TV 6	FM BC			
21.0 21.45		TV 3	TV 6	FM BC		TV 9	TV 13		
28.0 29.7	TV 2	TV 6			TV 6	TV 10-11-12			
50 54	FM BC		TV 11-12-13					UHF TV	UHF TV

Figure 10--Possibilities of harmonic interference from amateur transmitters are listed in this chart. Harmonics higher than 6th are not likely to escape from properly designed and operated transmitters. With reasonable care all harmonics can be controlled.

is very close to that of the TV audio carrier, come through understandably. However, in most cases when a TV viewer reports he is hearing rather than seeing amateur interference, a particular type of overload–rather than harmonic interference–is present.

This type of overload is not confined to TV sets; it may hit hi-fi equipment, hearing aids, AM radios, or almost any device incorporating an audio amplifier. Transistorized amplifiers appear to be particularly sensitive to such interference.

What happens is this: The rf carrier–which must be carrying AM for the signal to be heard–reaches the input stage of the audio amplifier by any of a number of possible routes. There, the amplifier's input stage acts as a grid-leak detector to demodulate the signal into audio; from that point on the amplifier is not able to tell the unwanted audio from the signal it is supposed to be processing, and you have interference.

The sure cure for this problem is to prevent the rf from reaching the amplifier input stage. The normal means of doing this is to add an rf bypass capacitor directly from grid to cathode of the audio stage involved. If an 82 pF capacitor is used virtually all rf will be removed and no audio will be affected.

How Is TVI Suppressed? Regardless of the cause, all TVI is suppressed by the same basic means; the interfering signal is disposed of. Exactly how this is accomplished depends upon the particular type of interference involved.

Interference due to overload requires action at the TV receiver. This action may be such a simple matter as installation of a high-pass filter on the TV-set antenna terminals, and may be such an extreme matter as completely shielding the TV chassis from your signal. As a rule, the less done at the receiver the better. If you can demonstrate that you cause no interference to your own set, you are in a position to wash your hands of the receiver-overload problem. The amateur is not responsible for design deficiencies in TV sets, and the FCC has recognized many times that many of the interference problems are directly due to TV-set design flaws.

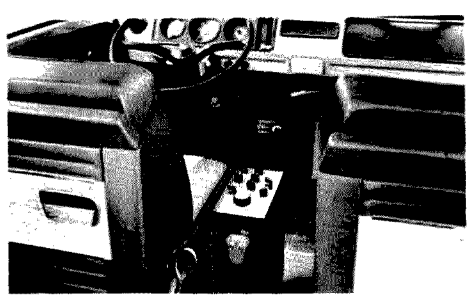
Interference due to spurious emissions is suppressed by suppressing the spurious emissions. All spurious emissions are illegal in their own right, and must be absent from your signal in order to be within the rules.

To suppress harmonics, the first steps are to be sure that as few as possible are being generated in the first place. Class C amplifiers should be operated with the minimum grid bias which will produce satisfactory operation. Tuned circuits should be coupled in a manner which will discriminate against harmonics and transfer only the desired frequency from one stage to the next. All power leads should be filtered and bypassed. Any stray resonances in the transmitter which happen to fall inside TV-channel limits should be detuned by adding capacitance, or have their Q killed by inserting resistance if practical. This will help hold the unavoidable harmonics inside the transmitter cabinet.

Tuning of all stages should be accurate, and a tuned antenna coupler should be used. "All-band" antennas are popular, but they offer no rejection of harmonics and should be avoided if TVI is a problem. A low-pass filter between the transmitter and the antenna will help reject high-order harmonics.

VHF operators face a somewhat different problem, as *Fig. 10* shows. The fundamental signal on 50 MHz can be more troublesome to Channel 2 than any harmonic of a HF signal. While sharply–tuned antenna couplers, and tuned–line wavetraps at the TV receivers, can help with this problem, the most reliable cure is simply careful operating practice. Choice of an operating frequency to minimize TVI, and of operating hours to avoid most viewers, does more to eliminate the problems than any amount of technical tinkering can accomplish in this case.

Next Month. VHF characteristics and principles of propagation will be our subjects in the next installment.



Factory Transceiver Installation

The ham crew at the Volkswagenwerk has been working on a ham mobile unit which may be released as optional equipment and be available through all Volkswagen dealers. Detroit, please take notice that the Germans are getting ahead of you again. That is the Drake TR-4 beside the seat. The power supply mounts behind the front seat cushion, out of the way. The whip (a Hustler) is on the back of the bus.

A NEW System For Learning Morse Code!

Robert C. Erwood, K9AAU
2823 W. Lyndale Ave.
Chicago, Illinois 60047

The difficulty of becoming a proficient Morse Code operator is apparent in that at least 25 hours of intensive study is necessary for the average person to learn to copy a modest five wpm. After disappointing experiences in teaching with the present methods, I have set about to scientifically devise a "best way."

When you take a message delivered in code, have you ever caught yourself making up your mind as to what the letter being sent is before the character has been completely received? This is significant in my new system of teaching code to beginners. It is based on the simple code structure.

All communications are made up of bauds. A baud is a length of time of tone or of silence. A baud is the length of time it takes to send a dot. Three bauds is the length of time the tone is sounded to send a dash. One baud is the time the tone is silenced between dots and dashes in building the code characters. Three bauds is the time of silence allowed between characters to distinguish them from one another.

If a beginner knows only two characters, say E (one sounded baud) and T (three sounded bauds) then, when he hears either of these two characters, he makes up his mind which it is after only two bauds. The third baud can be called 'slack time'. He is going to have to 'unlearn' this slack time habit and when a habit must be 'unlearned' progress is slowed. The beginner establishes the habit of determining the character after the second baud but when he learns the new character I (sounded baud, silent baud, sounded baud) he must suppress his habit and wait for the third baud before he can determine what the character is going to be.

An extreme example would be, if the beginner only knew E (one sounded baud) and Zero. He would know which character the teacher was sending after only two bauds because even though zero is composed of nineteen bauds, some sounded and some silent, he knows it is not E when the first tone sounded continues to the second baud.

The science of psychology tells us that learning is a continual process of establishing habits and having to suppress them and add new habits. This applies to learning the code. The characters should be taught in a sequence that will keep the necessity of changing habits to a minimum and not according to the frequency of use or according to surmised patterns of difficulty which are the current methods of presentation.

It is a known fact that tones can be compared which are only 15 milliseconds in duration. There is a strong tendency to decide what a character is as soon as possible and not wait for the end of the last tone. These two premises constitute the foundation of my new system for learning the Morse Code. The idea is to minimize the necessity of changing decisions which takes time.

There must be a scientific order of learning in order to avoid unlearning bad habits which will slow up any study. If a student learns the letters as they are usually taught without scientific order of sequence, bad habits will be formed which then must be unlearned. Receiving code is not the same problem as sending and for speed practice the teacher will send the code symbols the student has learned. Say E and Zero are the known characters and those are the ones the teacher is sending. The student will not wait until all the dashes have been sent before deciding it is a zero and not an E. The student will actually be making up his mind that the character is a zero after one baud when the first tone of the character continues three bauds and becomes a dah. Actually the student has heard T which he has not yet learned and he is deciding the character is a zero when there are yet seventeen bauds to go in that character. Thus the student is establishing a pattern he will have to break in order to learn T and M and O for example. To avoid this difficulty the student must learn the 9 along with the zero so

he will withhold his decision as to the identification of the character until the last tone has been sounded.

In my new system the first characters taught are the 9 and the Ø. Nine, dah-dah-dah-dah-dit and zero, dah-dah-dah-dah-dah have the similarity that the decision as to the identification of the character must be held off until the last tone is sounded. The beginner does not yet know that dah all by itself is T, or that dah-dah is M, or that dah-dah-dah is O, and is consequently not changing his mind regarding the identification of the character but is withholding his decision until the last tone.

The following is the progression of the characters as they should be taught. I have divided them into six lessons. Each lesson must be mastered before progressing to the next.

Lesson 1: 908OEI
Lesson 2: Z7QGM
Lesson 3: KCYDZ6B
Lesson 4: NTJPW
Lesson 5: IRA2FU
Lesson 6: 5H43VS

Letters

Tesla

Dear Kayla,

Thanks for the success story on Nikola Tesla—the best I've yet read on him. A good shot in the arm for the younger set!! I suggest more such stories for the incentive that it may help to create.

Sam J. Main, WØHQW
Brainerd, Minnesota

Dear Kayla,

FB on the life story of Tesla—let's have more of the same. I've been reading it mornings on the Net to the non-73 subscribers, hi. Let's have more of these articles about the *greats* who pioneered the electronic and electrical field.

Howard, KØHPF
Denver, Colorado

Dear Kayla,

Say...you really rang the bell here with that splendid article on Tesla in the February issue. I can't begin to tell you how much I enjoyed it. It was like having a philosopher at a science club. All technique and no history makes a magazine a dull read. Very bright and interesting.

James R. Belt, Jr., WØJIH
Omaha, Nebraska

Ed. note: Space does not allow for all the letters about this one article. There have been at least fifty with the same sentiments expressed above. Below is the one dissenter.

Dear Editor,

Why do you take up so much space with junk like the article on Tesla? This and other nontechnical articles make me inclined to cancel my subscribtion.

(Unsigned)

License course

Dear 73,

In reference to your article Getting Your Higher Class License (Part X—Basic rules and units) you have more than adequately described, among other things, impedance in the most common forms of resistance, and capacitive and inductive reactances in an admirable effort to avoid some of the trigonometry and calculus which often tends to snow a good majority of amateurs, not in the engineering field. Your staff should be commended on a fine job, one well worth the effort.

Stuart M. Kravitz, WA3BSC
Middletown, Pennsylvania

Dear Editor,

While I have read the publication for quite a few years, the quality of material lately has impressed me to the extent that I want to be assured of receiving every issue.

You are to be particularly commended on the series of articles on the Advanced Class License. These are truly outstanding. Even though I hold an Advanced License, I have learned a great deal from the material and wish I had had material of this quality to study when I took my exam. My compliments on an increasingly fine publication.

Dr. Lawrence A. Edler
Santa Cruz, California

Dear Wayne,

I want to extend my thanks to both you and your staff for an outstanding job on preparing and presenting articles on "Getting Your Higher Class License." I have read, re-read and outlined every inch of those articles. I'm happy to know there are people who will share their knowledge and understanding of the "State of the Art" in such superlative fashion. Mucho thanks.

Walter Seighman WA3AXQ
Belle Vernon, Pennsylvania

Dear 73,

I would like to add my "thanks" to 73 for offering the advanced Class Study Course. This course, which has been well put together, should make the necessary job of studying easier for those who will take the time to go through it.

Richard Gassman, WB6YIL

Dear Kayla,

This is to agree and disagree with your December editorial. The magic of radio still exists when properly sold by people like yourself. To qualify this, I just passed my Advanced exam, SOLELY due to your last nine articles. Face it, man, you can't find hams with time and ability to simplify and explain a complicated art. The old hack is memorize the answers, pass the exam, and learn later. Hell's Bells, that's why we have so many lids...they will never learn. Each article was well written and aimed at the man, like myself, with no knowledge of electronics.

Dr. Dan A. Farrell
Globe, Arizona

Bouquets and Brickbats

Dear 73,

My sincere congratulations to you and the entire staff of your publication!

The best amateur radio magazine that is for sure, complete and interesting. Please put me in the large list of good friends and fans of your non-plus-ultra publication. Keep up the excellent work for the benefit of the radio amateur family.

Joseph M. Francisco, ex LU6DEM
Whittier, California

Dear 73,

Congratulations on the quality of 73 Magazine. Your magazine is really top at all points of view and very interesting to read.

Gerard Bunge
Tucson, Arizona

Dear Wayne,

The front cover of the January issue sure has impact. It has me broken out in a sweat. I can't sleep. I can't eat. I've stopped looking at the "architecture" of the opposite sex. If I don't make it the first time up, I'm going to take my "Chicago typewriter" out of the violin case and mow the whole damn FCC crew down. Hi . . .

Frank A. Phillips, W5QPH
Houston, Texas

Gentlemen:

Last week when I stopped off at Uncle George's radio store in Wheaton, Md., for some radio parts, one of the clerks told me that 73 Magazine recently ran a series of articles on the questions and answers, and other information, on the new Advanced and Extra Amateur Radio Licenses.

"The best information on this subject that we have ever seen," is the way one of the clerks put it.

DX QUIZ . . . Answers

The quiz is on page xx.

Israel	040	Bermuda	111
Togo	081	Singapore	336
Burma	352	Iran	030
French Somoliland	047	Nepal	001
Ireland	048	Galapagos	178
Liechtenstein	046	Guam	303
Egypt	047	Canal Zone	165
Heard Island	137	Ascension Island	103
Hawaii	269	Virgin Islands	127
Venezuela	138	Ceylon	007

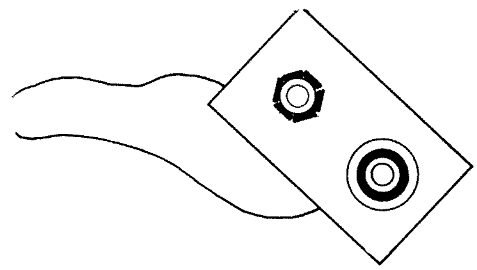
Score five points for each beam heading that you guessed within five degrees (Minnesotans should guess within three degrees). Don't feel discouraged if you didn't do too well. In a test similar to this a group of DXCC'ers averaged about one right. The top man had only three correct.

Solution To Cryptogram

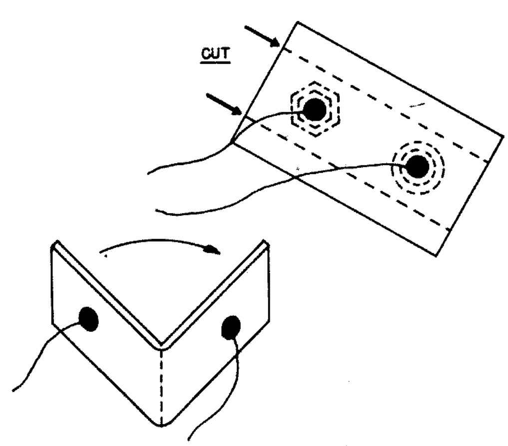
A changing electric field sets up a magnetic field, and a changing magnetic field generates an electric field.

Top Tip

If you use small transistor equipment, you probably have a pile of old dead 9V batteries in the junkbox. If they look too useful to throw away, maybe they are. Just grab one and twist off the metal casing, pull out the plastic top, and you have a 9V connector guaranteed to fit the same size battery from which it was removed. Solder on whatever you need in the way of leads and you're in business. See **Fig. 1.**



Old dead "B" batteries always seem to outnumber good ones, but there is a use for them too. Again, take off the top, which is usually cardboard or a thin fiber material. Now trim the top, as shown in **Fig. 2a**, fold in half, add leads, and (**Fig. 2b**), you have a free SPST switch suitable for haywired circuits or anywhere that you don't want to waste one of your good "store-bought" ones. The 9V tops are usually too stiff for this job, but if you want to go to the trouble of remounting the connectors on different material, they will work just as well. Now all you have to do is figure out something to do with the black junk that's all over your work bench.



David B. Cameron WA4VQR

I wonder if 73 Magazine has reprints of these articles available for purchase, or has considered publishing the series in pamphlet form. If you have reprints, I'd like to get a copy or two.

Jack R. Adams, W4TMJ
Falls Church, Virginia

Dear Sirs,

I would like to take this opportunity to say that the material in your magazine has deteriorated considerably in the past year. Improve, or my subscription will not be renewed.

B.S.Hargrave, K7NWN
Bellevue, Washington

Can't win 'em all, they tell me.

Odds 'n' ends

Dear Kayla,

Four years ago, when my husband, K5DGI, planted his ninety-foot tower in the middle of our rather small back yard, after promising that it would be well over to one side, we came up with the idea of planting climbing roses up the sides to camouflage the steel and wires. The roses have turned out to be quite attractive during the few weeks they are in blossom. However, the most useful side-effect has resulted from the thorns, which provided a highly successful year-round deterrent to the temptations of tower climbing by our own little boy and all the other neighborhood gremlins.

Mrs. Wesley Attaway, K5DGI
Shreveport, Louisiana

Dear Kayla,

A little gadget that is a handy operating aid for DX'ers can be made out of an ordinary desk calendar, though any small calendar would do, of course. The good propagation days on the calendar can be marked with a circle. Fair days left alone and poor days boxed.

My op aid is on a 3x5-inch file card with a little V-shaped cardboard support Scotch-taped to the back. It sits on my receiver next to my GMT clock.

The column width of the magazine will accommodate the art enclosed. It might look good at the top of the propagation column above the three data blocks. The only trouble with this idea, though, is that guys may be tempted to cut it out of the page, thus ruining the magazine. Maybe it should just be shown as an idea.

Alf Wilson, W6NIF
San Diego, California

Dear Wayne,

I am sure that your mail this month will include many interesting, and witless suggestions, with respect to your idea for dividing 20 meters into slots for homogeneous groups.

My contribution, however witless, is to suggest that we eliminate your designation of 14298, cultural discussion, as being totally devoid of interest to hams and that we set this frequency aside for the feeble minded; particularly those whose need to communicate is satisfied by the transmission of unidentified jamming signals.

Mike-fright may also account, in this day of thoroughly operational vox control, for the fact that QSO's still consist largely of interminable, alternating, hand-switched transmissions; distinguished both for vacuity and tedium. Vox operation soon discloses the conversational cripple, rendering small talk even smaller.

Frank Melville, W2AQK

Wayne Green

Just where does amateur radio stand today? And, where is it going? Obscenity on our bands...disenchantment with the ARRL... also with the FCC...worry about the ITU...the Miller 'effect' on DXing...home brew dying... movements to CB-ize our hobby...our empty Extra Class bands...growth of the hobby stopped...major manufacturers leaving or left for CB money...terrible QRM on a few bands ...wide open emptiness on others...clubs lanquishing...etc. Do we have more problems than we can solve? And, who is to solve them?

Let's briefly look at our background and then try to see where we are today.

The beginnings in any field of discovery are left to the amateur. The first radio amateurs were experimenters who built a good deal of their own equipment for the fun of it and got on the air with spark transmitters and fought QRN and, eventually QRM. Amateurs, naturally, were responsible for a lot of the important developments. As radio communications became a bigger and bigger business the ham bands shrank accordingly and more of the developments were made by larger companies who could afford the research engineers and expensive equipment required for the work.

By the late 20's commercial receivers were becoming popular and fewer and fewer amateurs took the trouble to build their own. Most of the amateurs built their own transmitters right up until WWII. This was because there were not enough amateurs to make commercial production of transmitters profitable at the time.

After the war there were so many surplus transmitters available that there was little incentive to go out and buy parts for building a new rig. With Command Sets selling for $5 which, with a little conversion, would give 100 watts of very stable VFO power on most ham bands, one would have to be crazy to spend $100 or so on parts to build the same rig. I remember buying a 100 watt Jefferson Travis surplus transceiver which covered 160-80-40 meters, AM phone and CW, a bunch of the Command Sets, SCR-522's galore, ARC-4's, a Meissner Signal Shifter, a BC-312 and an SX-28...all surplus and all of which I used for years. The Signal Shifter, with a little NBFM modulator I put in, connected to a pair of surplus 813's, let me work the world ...on all bands!

About the time surplus began to fade away our manufacturers saw that the ham market had grown big enough to make it worth while to add transmitters to their receiver lines. What ham in his right mind would go out and spend $200 for parts to build a rig that has no resale value worth mentioning when he could buy the same rig commercially for perhaps $250? A handful of amateurs continued to build their rigs, but they did it for the fun of building and had to recognize that economically they were in the hole.

Amateur construction did not die, by any means. Thousands of amateurs continued to build equipment...but now it was VHF gear which was not available commercially...RTTY terminal units...gadgets. Building projects in the ham magazines would often be duplicated by hundreds of readers. Probably only about 25% of the amateurs built equipment at this time, compared to the near 100% of the 30's.

Then came the transistor. Most of the older timers didn't even try to accommodate to the transistor. They went on for a year or two or even three building the tube circuits published in the magazines and ignored the transistors. As time went on fewer and fewer of those cartons of old tubes in the closet would fit into the new projects being published. Hardly anyone called for an old bathtub capacitor (condenser) anymore.

The percentage of home construction dropped. Most of the radio parts distributors went to selling complete equipment and CB rigs, leaving the parts jobbing to a handful of large mail-order houses. Gone was the day

(Continued on page 89)

Who's Who in Amateur Radio

Wells Chapin, W8GI
2775 Seminole Road
Ann Arbor, Michigan 48104

We have celebrities in our ranks. There are many illustrious and glamorous names in the Call Book. Oddly enough, however, despite their status in their various fields of endeavor, these well-known persons do not constitute an aristocracy within our midst. Far from it! For Amateur Radio, unlike other forms of activity, exemplifies true Democracy. It cuts across class lines with complete disregard for wealth, social standing, nationality and creed.

Many of our colleagues possess names which are universally recognized, and it is high time that we acknowledged their presence among us. At a point in time when we hear constant warnings that our frequencies are in jeopardy, we may help to preserve our allocations by generating a program of better public relations. It is certain that we can use a more positive image. And surely, publicizing the names and achievements of our more eminent and distinguished hams will tend to enhance that image.

There are hams in medicine, law, show business, the clergy, the military, Big Business, Government, foreign royalty, and two of us have even run for the highest offices in our nation.

Not because of established protocol, but because it seems a likely place to begin, here are some hams with the "Blood Royal" in their veins. P. T. Namgyal, King of Sikkim, operates from the Palace at Gangtok as AC3PT. He has an American wife, who probably complains about the unsightly tower and beams which disfigure the looks of the house, just as ours do. OE3AH is Archduke Anton von Hapsburg, the Austrian pretender. Moulay Hassan, CN8MH, is King of Morocco. In Saudi Arabia, where Ibn Saud, who was probably the last of the absolute monarchs in the world, operated as HZ1TA, three of the Princes hold ham tickets. Crown Prince Abdullah is HZ1AF, Prince Talal uses the late King's call, HZ1TA, and Prince Saud ibn Saud was HZ1SS. So much for the blue bloods.

I wonder how many who have visited that famous landmark in New Orleans, Antoine's, realize that it is owned and operated by Roy Alciatore, W5RU. Roy loves to QSL, and he usually sends a commemorative Mardi Gras medallion along with his card.

Many DX'ers are familiar with the call, UA1LO. Sad to say, this ham is now a Silent Key. He was the Soviet Union's intrepid Cosmonaut, Yuri Gargarin. Incidentally, it is being rumored that one of our own Astronauts, who is a ham. may operate a rig on a forthcoming moon snot. It is said that the operation will be on the 144 MHz band.

Here are several hams who have achieved stature in the entertainment world:

Arthur Godfrey	K4LIB	Radio & TV personality
Tex Beneke	KØHWY	Band leader
Bill Leonard	W2SKE	Radio & TV announcer
Alvino Rey	W6UK	Band leader
Harry Gumm	K6MDD	Circus clown
Mel Shavelson	W6VLH	Screen writer, producer
Andy Devine	WB6RER	Famous character actor
Dave Mann	K2AGZ	Songwriter of many hits
Bob Mersey	W2TXI	Recording producer, conductor
Ernie Lehman	K6DXK	Film writer (Sound of Music)
Julius Baker	W2TDY	lst Flutist NY Philharmonic
Paul Weirick	K6AK	Arranger (Lawrence Welk)
Jean Shepherd	K2ORS	Humorist, Radio personality
Luz Zuluage	HK6LT	Miss Universe 1959
Pee Wee Hunt	W1AYA	Famous jazz musician
Cliff Arquette	ex W6SGP	Charlie Weaver
Freeman Gosden		Amos
Bobby Byrne	WB2JDG	Trombone, record exec
Wilmer Allison	W5VV	US Davis Cupper

While we're on the subject of entertainment, 8XK, the ham station of Frank Conrad, later became known as KDKA. This station in Pittsburgh, was one of the pioneer stations in the crystal set days, and many's the hour spent manipulating the old cat's whisker, trying to pull in KDKA, back in the 20's. Really, the broadcasting industry owes its very existence to hams, for they laid the groundwork and experimented independently so that the principles of radio broadcasting could become a practicality. Prior to their work, radio was used solely for the communication of messages. The concept of broadcasting music, sporting events, Presidential Inaugurations, and such, was strictly the brainchild of hams.

Incidentally, there are many firms which make ham gear whose proprietors hold tickets. Art Collins, WØ CXX; Frank Gunther, W2ALS; Percy Spencer, W1GBE; Parker Gates, W9DZT, and many, many others. Bill Halligan, W9AC, founder of the Hallicrafter Corporation, was one of the founding fathers of our hobby, and deserves special mention.

Here are some outstanding business people who are amateurs:

Cyril Staud	K2DQ	Vice Pres., Eastman Kodak
Harry Vickers	W8HBY	Pres., Sperry Rand
Herb Scofield	W8DBH	Pres., TMC Systems
Buzz Reeves	K2GL	Reeves Sound Studios, etc.
George Davidson	K6EI	Exec., Standard Oil
E. Henderson (dec'd)	W1UDY	Exec., Sheraton Hotels
Harold Churchill	W2ZC	Exec., Time Publications
Bill Newcomb	K2CNX	Insurance Exec.
Harold Carlson	W2UNR	Exec., Associated Press
Findley Carter	K6GT	Director, Stanford Research
Bob Waters	W1PRI	Pres., Waters Mfg. Co.
Carl Lindemann	W1MLM	Vice Pres., NBC
Bob Ehrlich	W2NJR	Exec., AT&T

General Electric has over 1000 hams, and there are hundreds at RCA, Westinghouse, Bell Telephone and others. Ford Motors has a ham club with over 100 active members. There are amateurs in all sorts of industrial and commercial institutions. Banks, department stores, railroads, shipping companies, utilities, airlines, mining and smelting companies, steel and copper firms, newspapers, book publishers, advertising agencies, drug firms, oil producers; these are just a few categories of business where hams may be found.

The clergy is well represented. Father Dan Linehan, S.J., of the Weston Observatory, W1HWK; Father Tom Aquinas Cox, W2CBX, of the International Radio Mission Association; Father Chuck Tardiff, 5H3 Jack

Rabbit, and Father Moran, 9N1 Mickey Mouse, are some of the more well known ones. And there are countless priests, nuns, ministers and rabbis, chaplains, and at least one Greek Orthodox priest, all yacking away, even as you and I.

Many of us remember the sinking ship, Flying Enterprise, whose skipper refused to leave, even after he had ordered his crew to abandon ship. His gallantry made headlines all over the world. This was Kurt Carlson, W2ZXM, who can often be heard on 20 meters, operating maritime mobile from the seven seas.

The president of Louisiana State University is John Hunter, W5DTL. W1DDB is the reknowned sculptor, Allison Macomber. And, Bill Juhre, the syndicated cartoonist is W9IMQ. Ray Blosser, W8DBK, is vice president of a bank in Cleveland. We've got 'em all over!

Politics and the Diplomatic Service are not without hams.Of course, we all have heard of K7UGA/K3UIG, Barry Goldwater. Some of the less publicized ones are:

William Porter	K1YPE/XV5	Dep. Chf. of Missions in Viet Nam
Maurice Bienbaum	HC2KX	Ambassador to Ecuador
Armin Meyer	OD5XX	Ambassador to Lebanon
Dudley Mason	KW6CJ	Governor of Wake Island
Bert Delotto	W6FGY	California Legislator
James Homes	W6REK	California Legislator
John Doughten	W3LV	Pennsylvania Legislator
Carl Ruh	W4TZT	Kentucky Legislator
Frank Hazelbaker	W7FTP	Montana Legislator
John Thompson	W7OAZ	Montana Legislator
John McCarthy	K1EMO	Former Comm'r of Finance, Mass.

There have always been many hams in the military. Since communications are a vital link in the successful maintenance of a proper military establishment, it would be difficult to envision a situation in which there were no reasonably close relationship between the Defense Department and Amateur Radio. In times of crisis, we are expected to furnish a pool of experienced communications personnel, upon which the military can depend. This calls for some degree of liaison.

Some of the high ranking officers who who hold licenses are:

Rear Admiral H. Bruton	W4IH
Major Gen. Elmer (Bill) Littell	K3BNI
Gen. W. W. Watts	W4VI
Admiral McCarley	W6BSH
Admiral Weatherwax	W4PDW
Major Gen. Shuler	W4KN
Gen. J. Smith	W6RT
Adj. Gen. Windom	W8GZ
Gen. Joe Stillwell, Jr.	W4FPE

The history of Amateur Radio, indeed, that of electronics in general, is star-studded with many great names, each of which would be entitled to an individual article; their contributions have been so significant. Men like DeForest, Colpitts, Hartley, Meissner, Armstrong and Hazeltine, all hams, have given the fruits of their genius for the betterment of all humanity. Without the work of these pioneers, many of the marvels which make life easy today would not even exist. It is fair to say that these men were giants.

Thanks to the devotion and dedication of thousands of radio amateurs, the art of electronics has contributed greatly to world peace and friendship. Nations, once widely separated from each other, have been enabled to maintain lines of communication and avenues of peaceful approach.

International aspects of ham radio may generate further interchange, resulting in an atmosphere of genuine amity and good will among the nations of the world. It may spread out to the general populations, and finally reach up to the ruling circles. In this way, ham radio has an opportunity to make its greatest contribution of all. Hams everywhere have a justifiable reason to be proud of their hobby. There are few hobbies which are so capable of contributing to society.

A Stacked Gamma Matched Turnstile

Glenn H. Chamberlain, WA9LPC
4822 Prospect Avenue
Downers Grove, Illinois 60515

Having just acquired the desire to operate on the higher frequencies, I purchased a conventional two-meter rig and an eight-element commercial yagi antenna. It was immediately apparent that the local groups were impossible to copy readily using the highly directional antenna.

In reviewing the material in the usual handbooks, the stacked turnstile appeared to be the most promising compromise. However, the need to insulate the elements from each other, and the matching, seemed overly complicated.

Why not a gamma match eliminating the need for insulators? The elements were cut from 3/8 inch aluminum tubing for the center of the band, 146 MHz. Their length from the formula for a half wave dipole is 38 inches.

With the gamma match the elements could be bolted directly together to a common boom. Using number 14 wire, the gammas were connected 4 inches from the center connection of the elements running horizontal ½" above each element towards the center.

To provide a 90 degree phase shift between the elements of each turnstile, use a quarter wave section of RG-58AU. The half wave sections for 146 MHz, using the 0.66 velocity factor, is 26.6 inches for each. The entire antenna is then fed at the center of the two half wave sections with RG-58AU.

The antenna was hung about four feet off the side of the tower at the forty foot level. The feedline at this location is about 75 feet long. A 15 watt AM transceiver was used for the test. The standing wave ratio was 1.3 at 144.4 MHz, 1.2 at 146.0 MHz, and 1.3 at 147.6 MHz.

The band was open when the antenna was connected. Reception of an Iowa station about 145 miles distant from Chicago dropped one S-unit when shifting from the commercial eight-element beam to the home brew turnstile. In comparing my signal with this station, my signal also fell one S-unit when changing from the commercial antenna. If the commercial beam lives up to its specifications of 15.5 dB gain, this means the stacked turnstile has about a 10 dB gain on a long haul.

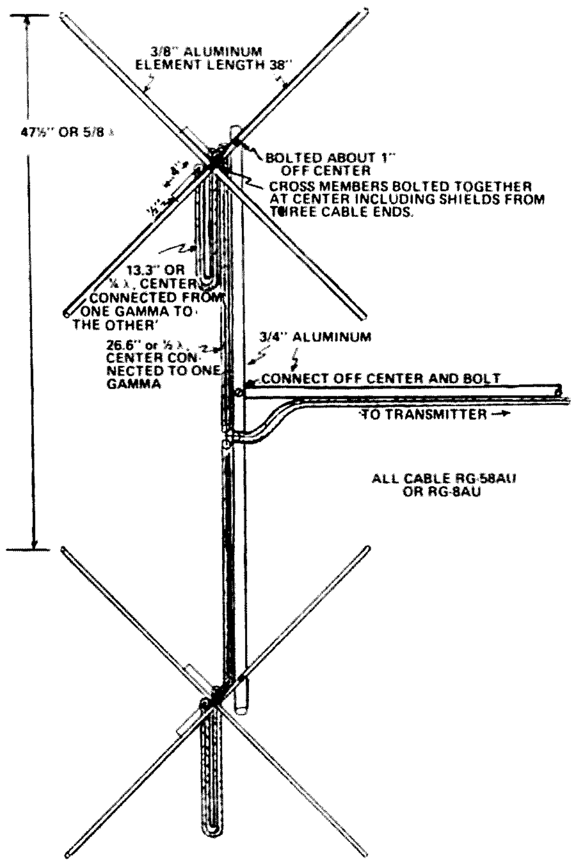

Fig. 1. The Stacked Gamma Matched Turnstile.

The antenna had excellent transmitting gain when using it in local group communication. Receiving was not quite as good. However, if more gain is desired, there is no reason two or three of these stacked turnstiles could not be hung around the perimeter of tower, each turnstile being fed with half wave sections of RG-58AU cable.

This antenna is simple to build, cheap, light, omni-directional and required no tuning after fabrication. At this QTH, we highly recommend it for those "local" schedules, and on the longer hauls you might be surprised.

...WA9LPC

The VHF Vacation Special

TSgt Robert H. Wilder, W2ZRX/4
Box 23, 693 Radar Sqdn
Dauphin Island AFSTA
Dauphin 15, Alabama 36528

For years I have been associated with the theory of using a simple whip or wire antenna and pumping as much power into it as you can to work as far as needed. This, of course, is a necessity if high mobility required for military communications is to be achieved.

With this background I found that for amateur operations this usually didn't work if you want a highly portable, cheap but efficient vhf antenna system.

The whole idea was to build an antenna from materials at hand in the average home. Using this premise a covey of antennas ranging from ground planes, verticals and simple beams were constructed out of metal coat hangers; collinears from aluminum clothes line and even the TV log periodic when re-runs were the only thing available to watch.

The latest, which is discussed here, was built out of some aluminum foil I scrounged from the XYL. (She is WA2YXE and it sure helps when you start taping the foil to the walls).

The "slot" antenna in its basic configuration of a plane surface is not usually used in either amateur or commercial applications. Commercially the slot antenna has been in use for several years, but, as in the case of navigational systems such as TVOR, four cylindrical slots are rotated electrically to obtain an extremely accurate circular radiation pattern.

Some basic theory of the slot will be needed if a practical antenna is to be built.

The slot can be considered a length of shorted open transmission line one-half wavelength long, so the standard current, voltage and impedance curves apply as seen in **Fig. 1**.

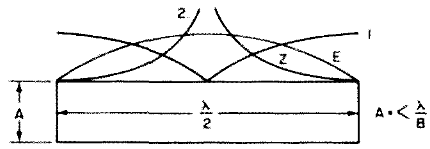

Fig. 1. Basic slot antenna.

The simple slot is nothing more than a ½ wavelength by .15 wavelength rectangular hole cut in a sheet of metal. The width of the slot is small at the higher frequencies, but with current flowing over the entire surface of the sheet (both faces) and not restricted to the slot edges, the capture area of the antenna is extremely large.

The interesting point is that if the slot is cut vertically to the ground reference **(Fig. 2)**, the antenna will be horizontally polarized and conversely horizontal slots **(Fig. 3)** are vertically polarized due to the development of the "E" fields of the antenna.

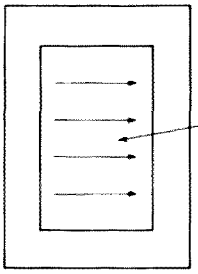

Fig. 2. Horizontal polarization.

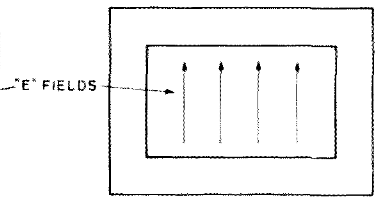

Fig. 3. Vertical polarization.

RG-8 or RG-58 coaxial cable can be used to feed the plane surface "slot" antenna even though the nominal center terminal impedance of a resonant ½ wavelength slot in a large metal sheet is in the neighborhood of 500 ohms. Feeding the slot with the 50

ohm coaxial cable off center will offer a fairly close impedance match between the feedline and the slot. The theoretical distance from either end of the slot is 1/20 wavelength, but the exact point must be found experimentally for each installation as surrounding structures offer some change to the impedance characteristics. The "Rule-of-thumb" is to start at the 1/20 wavelength point and work both ways until an optimum match is achieved.

The aluminum foil "Slot" antenna is the ultimate of simplicity in construction as can to be seen from **Fig. 4.**

The figures in Columns A & B were computed from Length (Inches) = 5905/Freq (MHz) and will work as is, but the figure in Column C must be found thru trial and error. I found that the distance from the end computed for 1/20 wavelength worked better from the middle.

For the best operation some method of bonding the coax to the sheet is necessary. I found that transparent tape can be used with little or no loss of power transfer if the tape is tight over the coax conductor and shield where it comes in contact with the sheet.

After construction of the slot antenna you should have something that looks like **(Fig. 5).**

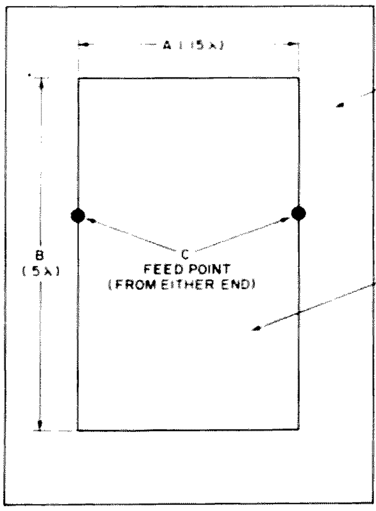

Fig. 4. The VHF Vacation Special. 65" sheet of 18" wide aluminum foil (a). (b) using chart 1 for measurements, and a single edge razor blade, cut out center piece and discard.

Freq MHz	A Inches	B Inches	C Inches	Distance from end I used.
144.0	12.30	41.00	4.10	17.40
144.5	12.26	40.88	4.09	17.41
145.0	12.23	40.75	4.08	17.42
145.5	12.18	40.60	4.06	17.43
146.0	12.14	40.45	4.05	17.45
147.5	12.08	40.29	4.03	17.47
147.0	12.04	40.13	4.01	17.49
147.5	11.99	39.98	3.99	17.51
148.0	11.95	39.83	3.98	17.52

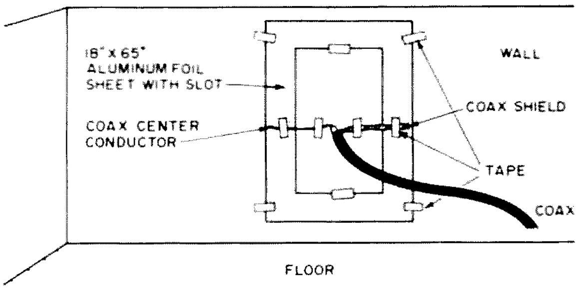

Fig. 5. Complete slot antenna. If mounted on a door it can be rotated to cover all directions.

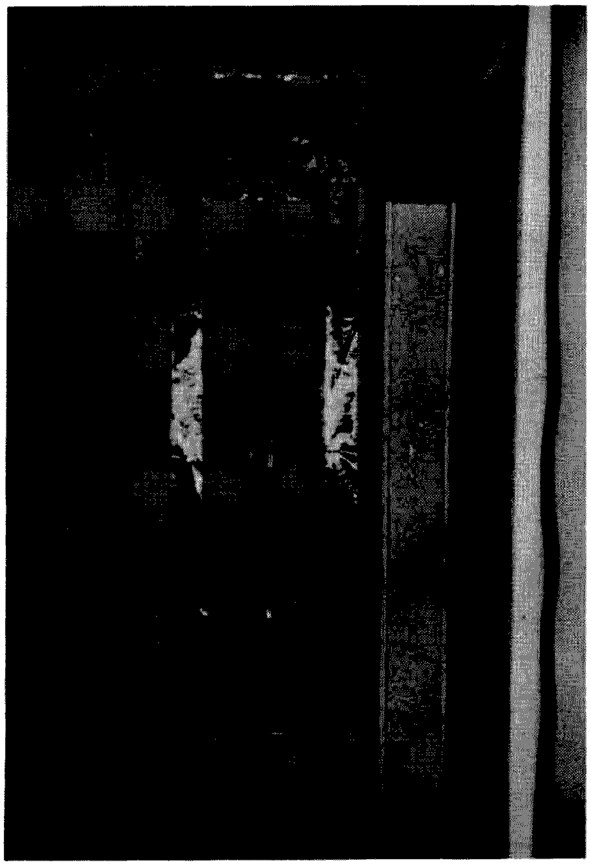
The two major lobes of this antenna will be through the slot, perpendicular to the plane of the sheet. As seen from the top of the antenna (see arrow in **Fig. 5**) you can expect a pattern similar to that shown in **Fig. 6.**

If this antenna can be mounted on a door



144.OMC slot antenna, horizontal polarization.

near the transmitter, rotation of the pattern will be possible. It was found that by swinging the door 90 degrees signals that were a clean S-9 dropped sharply to below S-4.

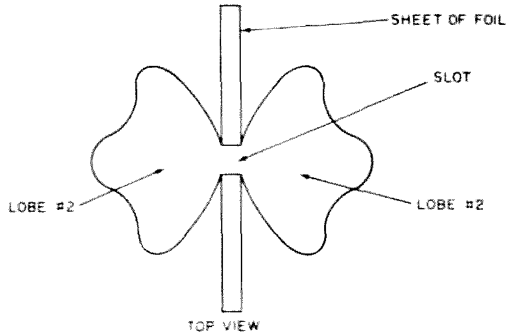


Fig. 6. Top view of radiation pattern of the slot antenna.

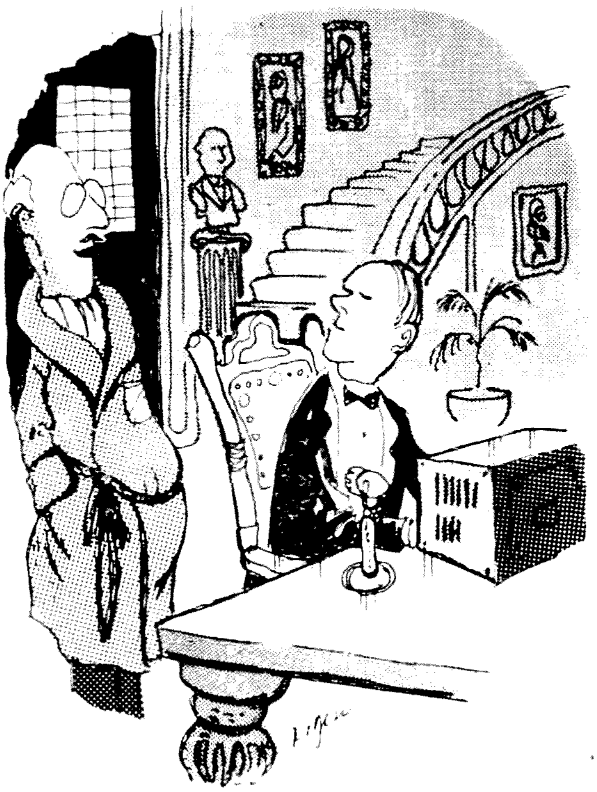
This antenna has out performed everything built to date including a ground plane at 25 feet above ground and the TV log periodic at 50 feet above ground. Reports have been exceptional up to 25 miles on the 143.950 MHz MARS frequency which is good on the Mississippi coast. Super regen receive such as the "Twoer" are completely quieted at 15 miles with less than 5 watts fed to the slot.

...W2ZRX



"Allow me to tune, Roggs—I need the exercise."

"S" Unit Attenuator

Edward A. Lawrence, WA5SWD/6
218 Haloid
Ridgecrest, Calif. 93555

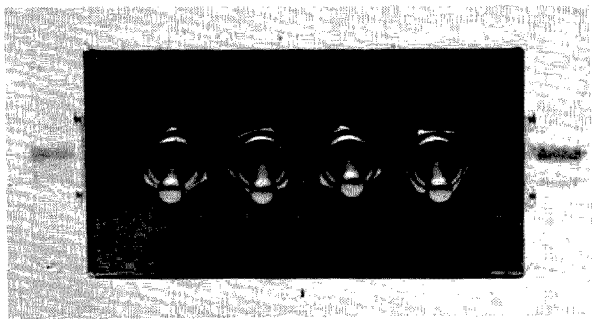
Since the topic of "S meters" is a popular one among radio amateurs, a lot of time is spent describing these devices, usually along the lines of how generous or "Scotch" the meters are at the QTH of the parties in the QSO. After a few such QSO's, I decided to build an attenuator, calibrated in "S" units. My aim was to attain an accuracy of 1 db or better, using 5% ½w resistors and simple construction so it would be easy to duplicate. What I wound up with is very similar to the attenuator described on page 40, January '67, 73.

As a sidelight, I started out by calculating both "tee" and "pi" pads, and used "pi" because all values of resistance are close to standard values, but (especially for high attenuation pads) the values for "tee" pads can get quite small; and expensive.

I figured the values required from the tables in the Allied's "Electronics Data Handbook", page 8, 5th edition. (Allied Radio, 75c, full of good info.)

Since "S" units are supposed to be 6 db, I figured data for steps of 1,2,4 and 8 times that amount, or 6,12,24 and 48 db. With these steps, any number from 0 to 15 "S" units of attenuation could be selected. However, 8 "S" units proved to be too much for one step, as shown by the lowered attenuation at 30 MHz, due to the inherent shunt capacitance of the resistor used in the series leg, plus the stray capacitance of the switch. So I removed the 8 "S" unit step and installed another 4 "S" unit step. This allows selected steps of attenuation from 0 to 11 "S" units.

Here are the values I calculated, and the actual values used, based on 51 ohms. The steps are switched in series, as required for the desired attenuation.



Front panel showing the switches for the various steps of attenuation.

Resistance Values for 51 Ohm Attenuator:

		R1		R2	
"S" units	DB	ideal	actual	ideal	actual
1	6	154	150	38	39
2	12	85	82	96	100
4	24	58	56	405	390
8	48	51.5	51	6400	6800

After the attenuator was completed, the attenuation was measured at 3 kHz and at 30 MHz. With the test equipment available it was possible to measure more accurately at 30 MHz than at 3 kHz. Below is the data from the tests.

Atten Step		Predicted	Measured	Measured
"S" units	DB	atten DB	at 3 kHz	at 30 MHz
1	6	6.2	6.0	6.02
2	12	12.3	12.2	12.16
4	24	23.3	24.2	24.05
8	48	48.5	47.5	39.11

Now if we want to make an educated guess as to how far up we can expect good results, say 1 db error out of 24 db, then we can use the measured error in the 48 db step to calculate the capacitance across the series leg, and from that calculate the frequency where the 1 db error will occur. Go through the math if that is how you get your kicks, or take my word for it. It comes out to about 2 pF. And this will cause a reduction of 1 db at about 220 MHz. And since the resistor is

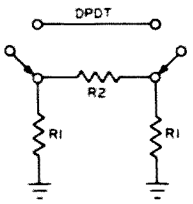


Fig. 1. Diagram for one step in the attenuator.

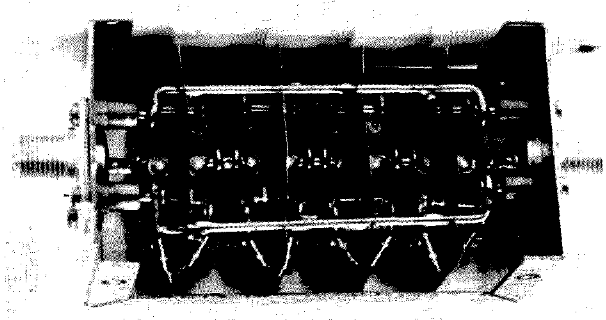
of a lower value for the smaller steps, they should hold their values to even higher frequencies, but I expect other factors would get into the act along the line somewhere. I will state that still works well at 2 meters.

If you want to get fancy, you can always figure the values for 1, 2 and 3 db steps and have from 0 to 72 db attenuation in 1 db steps.

Referring to the photos; you can see I built my attenuator in a Bud Minibox CU-2102-A, 4" X 2-1/8" X 1-5/8". Four steps is the maximum in this size box, unless different switches are used. Mine are Cutler-Hammer 7592K6. The shielding was made from transformer strap, but could be any soft copper available. Try a Hobby Shop and get the thin sheet that is used for embossing if all else fails.



Looking inside the attenuator.

Here are some of the uses an attenuator of this type is suited for:

Checking receiver "S" meter calibration.

Attenuating signals to aid in peaking receivers and converters.

Calibrating diode voltmeters for *rf* measurements.

Checking antenna gain. Or gain of that outboard *rf* stage.

P. S. My "S" meter lies, just as I thought!

. . . WA5SWD/6

Armed Forces Day, May 17

Contacts may be made on CW with WAR (Washington) on 4001.5, listening 3.5-3.65; 4020, listening 3.65-3.8; 6992.5, listening 7.0-7.1; 7325, listening 7.1-7.2; 14405, listening 14.0-14.2. NSS (Washington will be on 3385, listening 3.5-3.65; 7301, listening 7.1-7.2; 14400, listening 14.0-14.2; 21500, listening 21-21.25. NPG (San Francisco) will be on 4005, listening 3.5-3.65; 7495, listening 7.1-7.2; 13975.5, listening 14.0-14.2; 20954.5, listening 21-21.25. AIR (Washington) will be on 3397.5, listening 3.5-3.8; 6997.5, listening 7.0-7.2; 13995, listening 14.0-14.2; 20994, listening 21-21.1. Times are 171400Z to 180245Z.

SSB contacts may be made with NSS on 4040, listening 3.8-4.0; 7336, listening 7.2-7.3; 14385, listening 14.2-14.35. NPG will be on 4001.5, listening 3.8-4.0; 7301.5, listening 7.2-7.3; 14356, listening 14.2-14.35; 21600, listening 21.25-21.45. AIR will be on 4025, listening 3.8-4.0; 7305, listening 7.2-7.3; 14397, listening 14.2-14.35.

RTTY contacts may be made with NSS on 4012.5/3.65-3.8; 7380/7.0-7.2; 13940/14-14.1. NPG will be on 4016.5/3.65-3.8; 7347.5/7.0-7.2; 13922.5/14-14.1. AIR will be on 3347/3.5-3.8; 7315/7.0-7.2

Watch for a plane flying between Washington and Boston on 143.82, listening 144.0-145.5 on AM and RTTY. Also one flying between Los Angeles and Seattle on 143.7, listening on 144-148 AM. Mt. Diablo will be on 148.41 on AM/FM/RTTY, tuning 144-148.

CW Receiving Contest

At 180300Z (2300 EDT, 1900 PST) May 17th at 25 wpm, there will be a special Armed Forces Day message on WAR on 3347, 6992.5, 14405. On NSS on 3385, 7301, 14400, 21500. On NPG on 4005, 7495, 13975.5, 20954.5. On AIR on 3397.5, 7315, 13995. On A6USA on 6997.5.

RTTY Receiving Contest

At 180335Z at 60 wpm WAR will transmit the message on 3347, 6992.5, 14405. NSS on 4012.5, 7380, 13940. NPG on 4016.5, 7347.5, 13922.5. AIR on 3397.5, 7315, 13995. A6USA on 6997.5. A5USA on 4025.

Send entries to Room 5A522, Pentagon, Washington, D.C. 20315, before 31 May.

In the Beginning...

Bob Manning, K1YSD
915 Washington Road
P. O. Box 66
West Rye, New Hampshire 03891

Not long ago – 'twas October 3rd, 1968 to be exact, I was pouring L.S.D. into the air conditioner – I had taken an overdose of Midol barely 28 days previously and was morosely ruminating over the plight of the radio amateur. I remember the date very well. It was the fifth anniversary of ARRL's first Incentive Licensing proposal to the F.C.C.

Since we were about to 'gird our loins' and march valiantly back into yesteryear to the 'golden' or 'good old days' I had just ordered a 1936 Hudson Terraplane, dusted off all my old Rudy Valley records, bought up enormous quantities of lamp wick trimmers, pinned on my Alf Landon and Wilkie buttons and started building a two-holer replete with quarter moon, corn cobs and Sears Roebuck catalogs.

I was looking forward to going backward and seeing horse drawn carriages, apple carts, bread lines, WPA workmen and the return of spats, bustles and cholera.

Without warning, I was seized by *'holographitis'* which is similar to *'inspirational graphitee,'* but occurs outside water closet areas: 'tis an uncontrollable urge to write – something! – somewhere! I immediately seated myself and pounded out an article entitled, "Ipecac Works on Lids" (73 magazine, November 1968).

The response to this article was overwhelming! The fact that 'both' letters were written on foolscap with crayon and in block letters made little, if any, difference.

The Editor of 73, upon securing my release from the Intensive Care Unit of the local Domicile for Dememted Ding-a-Lings suggested I write more articles of similar ilk.

In the coming months and subsequent articles, I shall – by drawing on a seemingly bottomless pit of banality – endeavor to look at the foibles, follies and idiosyncrasies of amateur radio in such a way as to be humorous and satirical without being offensive.

If I am to be thusly foisted upon you, it is only fair that – like in *high class* books – you receive a resume' of my bona fides. 1. how had I become a ham and 2. what had put me on the path of *'holographitis'* besides a case of 'hoof and big mouth' disease and a diarrhetic typewriter?

How had I become a ham? Ah yes, I remember it well. Like most things I do, I did it backwards. Most hams become interested in amateur radio and then get their license. I got my license and only then did I become interested in amateur radio. This statement requires some explanatory background.

I spent 9 years in the U.S. Navy as a radioman and then, after a short stint with a British Thermal Unit (that's a hot one!), I transferred into the Air Force (ours). While I was in the Navy, I was considered an idiot

by those whom I thought were of high intellect. In the Air Force, the exact opposite was true. To this day I haven't figured out whether 'tis better to be thought an idiot by genuis' or a genius by idiots . . .

This variance of feelings was not, in reality, without basis. For, when I entered the Navy, it was with the understanding that I would be schooled as a Hospital Corpsman and study under the famous Doctor Chicago, who was doing experimental research in 'acne' and 'hickey' transplants. Unfortunately, the 'powers that be' discovered that I was color blind and, in their infinite wisdom, transferred me into Radio/Electronics – have you ever seen a color blind person trying to decipher the color code on a resistor? The process, like the mating habits of the penguin, is strictly 'trial and error' *(Incidently, the trial and error mating habits of the Penguin is probably the reason for that creatures universal disease, 'pknobophobia' (fear of backing into cold door knobs) and the most likely reason for their Charlie Chaplin-like walk and accounts for the fact that you never see a Penguin in a crouched or bent over position.).* This deficiency on my part led my superiors to look askance at my attributes. Combine this with my chubby, pear shaped appearance – which gave me the unique distinction of being the only man in the history of the U.S. Navy to ever wear a Bell Bottomed *Shirt!* and their feelings become understandable.

Of course, the fact that I once suggested replacing the old libido controlling saltpeter practice with a *'dry ice'* treatment did little to change their opinion. Instead of surreptitiously inserting saltpeter into the food fare, I proposed swallowing small dry ice capsules to freeze the prostate gland – thus arriving at the desired result without altering the taste of the food. Unfortunately, although the process did work, the side effects were nothing short of spectacular! It not only accomplished its original purpose, but also froze the larynx and the colon. The latter action created some extremely embarrassing situations for the user and the former action precluded him from calling for assistance.

Despite these obvious drawbacks – and the fact that I suffered from chronic seasickness, I became an excellent radioman. My last official test CW paper was accredited with 40 wpm. I must confess, however, that the officials simply took my word for my own test results. The tests had been given during heavy seas and the judges – to a man – exhibited a strange reluctance to either handle or even look at my paper.

Possessing the ability to send and receive CW at 25 and 35 wpm respectively and having trained on a great variety of electronic equipment, it was only natural that, when I transferred into the Air Force, that they would put me to work in a Teletype tape delivery center – where the only electronic mechanisms were a moldy coffee urn, a Tucker built coke machine and the ever present 'panic button'.

Eventually, however, I did end up in communications at a USAF MARS station where I made my first contact with the amateur radio fraternity. The Sergeant I worked for – call him Sam – held a 'Conditional' class license. Now, at that time, I knew nothing about the licensing structure and mistook the disdain shown towards Sam to be an aspersion on the type of license instead of the man. Whenever we held MARS meetings, the members flicked ashes in Sam's lap, lobbed candy wrappers at his Metrecal, accused him of having rubber pockets to steal soup and stated that, "if he had a brain, he'd be arrested for smuggling trash!"

Having no special love for Sam and being blessed – or cursed – with a caustic tongue – and knowing the disdain in which he was held, it was inevitable that we should eventually tangle.

It happened! - - - - One day, with Sam driving our 5 ton truck and with a burly airman seated between us, Sam managed to manually manipulate the controls of the truck in such a fashion so as to knock down two light standards, remove all the warning lights from the rear of the vehicle, open a new entry way into the MARS station, scare hell out of two pregnant dependents and caused the airman to slide, in a kneeling position, downward and forward under the dashboard where he straddled the drive wheel lever with considerable force – leaving him with a strange falsetto voice that may well have given rise to the eventual popularity of Tiny Tim.

Recognizing an opportunity to insert a verbal barb, I leaned across the agonized airman and asked, "Hey Sam – you got a 'conditional' drivers license too?"

There is no ire quite like that of an aggravated NCO and Sam was no exception. He immediately turned apoplectic vermillion, let out a 15 minute non repetative string of expletives and jammed on the brakes – once

again doing injury to the already anguished airman on the floor who, looking up at us with ƆMƆ blazoned across his forehead and, in a voice pitched somewhere between Jeannette MacDonald and Yma Sumac said, "fer cripesakes! ya dummy! you do that one more time . . . my navel's gonna look like a chin cleft and I'm gonna be wearing my truss for love beads!"

The final outcome of this incident was that Sam and I made a hot headed $5 bet that we'd both have General Class tickets within 30 days. Even though I managed to obtain mine in 28 days, I was unable to collect. The Air Force, learning of Sam's unique ability as a truck driver, had transferred him as an instructor to a heavy equipment school. There I was–I had a ham license and didn't know what to do with it.

Since that time, I guess I've progressed normally through the various stages of 'being a ham'–I began thinking up witty 11 meter type phonetics for my call sign, designed and scrapped hundreds of provocative QSL cards, progressed into the short purposeless QSO "hi there–I'm Bob– – broken old bottles – ur five nine – opps chow call – c u l" then gravitated into the public service field where I was prepared to battle my way through wind, rain, snow, sleet, hurricanes, typhoons, hippie uprisings, draft card burnings and other similar disasters to deliver *the* vital message thereby saving countless lives and millions of dollars and be awarded the 'purple clavicle' with 'oatmeal clusters.' I then took up the contest type operation– – "yeah, let's see – if I multiply my input power by the number of stations, add 5,000 for delivering a confirmation to the SCM, divide by the temperature, subtract 10% for being an appliance operator, add 127 points for having read the CD bulletin, figure the logarithmic value of pi R square (pie are square???? NO! pi are round–fig newtons are square) ah....ta hell with it– – – I'll cheat. I then settled down to appreciating and happily indulging in all areas and, to paraphrase Will Rogers, "I never met a ham I didn't like!" – Eventually, I reached the epitome of all hams.... writing sarcastic letters to ARRL.

This covers HOW I became a ham.... now, how had I sunk to the depths of satirical writings??

(International Business and newly formed countries want our frequencies, zoning laws restrict antenna heights, neighbors ogle us uneasily with awe – or fear – as if they expected us to mumble some voodoo chant, do two back flips and an arabesque, snip a lock of hair, sprinkle them with dried octupi eyes or dandruff and transform either them or ourselves into a 'fried egg sandwich'. TV viewers assail us for supposedly screwing up their twenty-one year old $37 Japanese TV set with the bamboo antenna and, on at least one occasion, hams became the topic of controversy in – of all places – an advice to the lovelorn column, our Mothers think we're gonna blow up the world – or at the very least – the house and our wives wish we'd forsake amateur radio for more sensible practices like 'bulb snatching' or 'skydiving' or become peeping toms, or winos or study the abnormal sex life of the African Anteater.)

Being a student of Zen, Extratenialism and intensely adroit at deep analytical introspective soul searching – which, literally translated, means "I goof off a lot!" – I have given considerable thought to this status. I have concluded that objective humor – satirical, distorted or prismatic is about the only thing that keeps me from running, stark naked, out of the house attacking the first AT&T truck I see and grabbing my neighbor by the throat, standing him on tippy toe and driving him into the ground with the motor end of a sump pump.

There are, of course, other alternatives that a ham may use as a relief valve. Among them is the process (which is becoming more and more popular) of submitting random proposals to the F.C.C.

I know of one radio amateur whose demented half brother, Alf, submitted a proposal within the past week. Alf, being the offspring of a neurotic and psychotic (those mixed marriages never seem to work out) and as an impartial outsider has rather an objective view. He submitted what, in the light of some of the more recent events, seems to be a palatable system for future Incentive Licensing.

Alf's suggestion is that all amateurs be immediately reduced to Novice class and issued new licenses combined with a fixed amount of marbles secreted in a cummerbund. (choice of colors – marbles and cummerbund – is optional). As the operator operates, he must assume anatomically impossible positions – like standing on his head with one foot stuck out the nearest window – a G.I. can may be fastened 6'6" above the floor as an effective substitute –

(Sometimes, when I make like an SWL, I'm not absolutely sure that this procedure is not already in effect)—In this way, the operator must manage to loosen the marbles from the cummerbund. His operating privileges will be inversely proportional to his supply of marbles. This will continue until he reaches the pinnacle; i.e., the highest grade of license and the 'loss of all his marbles'! Note...Alf submitted an addenda suggesting new classes of license— —I don't know them all, but they run something like this: (a) the Dummy class (b) Novice (c) Apprentice (d) Mediocre (e) Mundane (f) Technician (g) Adequate (h) Advanced (i) Improving (j) Extra (k) $_{\pi}\Sigma{=}\ \pm\div\_\,^{-}\cdot\pi{+}{=}^{32}$ and the (l) Whoopee class...

One item I feel I should inject to round out my resume' is the fact that I am quite vain. Besides being large of girth and tired of fun being poked at my expanse, I was once totally bald.

Because of that hairless state I paid a thousand dollars for a complete 'Follicle Graft'. (The operation, for the uninformed, is the transplanting of hair and roots from a volunteer donor to the top of the head of the recipient).

Regretably, in this case, the grafter used the hair from the hind leg of a German Shepard and, since the operation, I've fallen in love with a State Trooper, have a constant craving for ALPO, my backyard is pockmarked from my inept attempts at burying bones, I can't stop chasing cars and every time I pass a fire hydrant, the whole head of hair snaps straight up!

I hope you will find some enjoyment in the articles. Even though I once thought 'verbiage' was verbal garbage and 'sagacity' implied some physical malformation, writing is not a new thing with me. I am the author of one article entitled, "Where Are The Men?" it dealt with the poignant question 'where is MR. PAUL, UNCLE JEMIMA and WHISTLERS FATHER?? – I then wrote a ditty titled, "   on the Range" and, finally, I am putting together an amateur radio study book to be called, "I'VE UPPED MY OPERATING PRIVILEGES .... NOW ....UP YOURS!!!!!"

Friendliness and Courtesy are contagious . . . start an epidemic (K1YSD)

Don't Kill Your Generator!

Jim Ashe, W1EZT

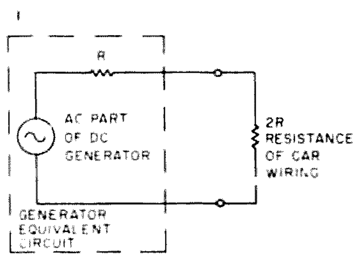
Going to filter out that noise from your car generator so that you can better enjoy your mobile rig? Careful, or you may kill your generator, too. It's been known to happen.

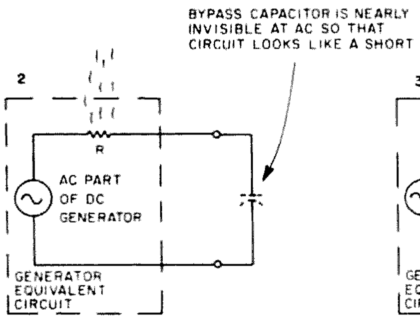
Since generators put out dc, it seems reasonable that a little old capacitor (or a little new one) across the output shouldn't hurt anything. But it's a fact the output is something more than pure dc, or you would not be thinking about filter capacitors. Now, when you put a capacitor across the output you are shorting all that hash, noise, and ac that the generator makes, straight through to ground. Are you sure you want to do that? See Fig. 1.

All dc generators are really ac generators. You don't see the ac because it's rectified at the commutator. But the commutator doesn't do a perfect job, and there is some sparking there too, so that there is a lot of noise power available at the generator terminals.

In normal generator operation most of this power is dissipated in the car's electrical circuit, which has a fairly high resistance compared to the generator resistance. But when you put that capacitor across the generator's output, while the dc is not affected, all that noise power is now dissipated inside the generator – right in the armature, as illustrated in Fig. 2. If the generator is working hard anyway, perhaps during mobile operation, the increased dissipation may be enough to push it over the edge. Result: you buy a new generator armature.

But it's not hard to avoid that trouble, if a filter capacitor is needed. What if you add a small resistor in series with the capacitor? See Fig. 3. Now the ac is still provided with the relatively easy route across the generator terminals, but less power is dissipated since circuit resistance in increased, and most of the power goes into the outside resistor where it does no harm. You get your filtering, and the generator survives. Try it this way, next time!





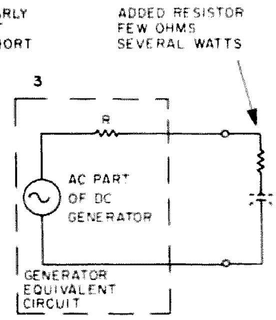


Fig. 1. Equivalent circuit at ac of an automobile generator installation. Resistance of car wiring is probably larger than that of generator by a factor of 2 to 5.

Fig. 2. If the car generator terminals are bypassed with a good capacitor, they are shorted so far as ac frequencies and noise are concerned. With reduced resistance greater currents flow, and the ac energy dissipated in the armature is several times greater than under normal conditions. At heavy generator loads the armature may deteriorate rapidly, or be destroyed.

Fig. 3. The simple solution. A small resistor added in series with the capacitor reduces currents and carries much of the ac dissipation outside the armature. A few ohms should be appropriate, and checks may be made by temperature observation or direct measurement of armature noise and ac currents.

Working DX Without Six Elements

Joseph E. Taylor, K5PAC
6 Evergreen Court
Little Rock, Arkansas 72207

Obviously, you won't work as much as often as the fellow on top of Crow Mountain with six elements, wide space, on a 100-foot tower and a 2 KW rig.

But you and I have already learned to adjust to that fact of life in our every day competition with the "big sigs".

The point is – you can work a surprising amount of DX of all sorts with Q5 QSO's if you go at it right.

Many American hams do not venture into the DX portions of the bands because they feel that they are not well enough equipped to work any DX. It ain't necessarily so!

So you have only 90 watts and no beam and very little chance of improving either – you can still work DX and enjoy it.

Maybe we ought to ask, "what we mean by DX", since not everyone means the same thing.

Old Charlie on the mountain has nearly 300 countries confirmed now. To him DX is another new country. "So what's another MP4 if you already have cards from each one that counts?"

But to most of us DX is that unique satisfaction that is associated with calling a fellow ham in another country, whether 3,000 miles away or 10,000 miles around the globe, and hearing him come back with that sweet sound that is our own personal private call! And the thrill is apt to be all the greater if we are operating with what we know to be less than the ultimate in equipment. A VQ9 on a beam or a quad is satisfying to be sure, but on a dipole there is an added dimension to the enjoyment.

By this I am not advocating that you use anything less than the best combination of equipment and antenna you can muster. The six element beam is wonderful if you can swing it, but my point is, you aren't out of the running if you can't.

A word needs to be said about what is meant by "working" DX too. For some fellows it is an exchange of RST, QTH and 73's. For others it involves a greater degree of getting acquainted as person with person. Where you will want to find your own maximum satsifaction is up to you alone.

Admittedly, it is harder to maintain a DX contact than it is to get one. So your percentages go down as your time in QSO goes up. In effect each of us works out his own pattern here.

CW or fone? Again we have to look at plain facts. Your chances with lower power and/or simpler antenna systems are better on CW than on fone. A good receiver can dig out and render copyable an extremely weak CW signal that would be hopelessly buried on SSB, let alone AM.

So, if you can do so enjoyably, you will have improved chances of success in CW operating. Don't be overly worried if your CW isn't perfect and your speed is down. DX operators are among the world's best at matching speeds. You will find fast ones and slow ones and very nearly all of them are patient, so don't chicken out on this score.

O. K., so you are ready to try – now for some concrete suggestions which will improve your chances of success.

1. Check your rig thoroughly. The fact that your power is limited doesn't mean your efficiency needs to be.
   A weak driver tube may not make much difference in rag-chewing in the 75 meter net. It may lose you many contacts in DX operation. Try to make sure your transmitter is at 100% peak of efficiency. Make sure your signal is clean and well keyed. Whatever your final power rating, you don't need to lose any unnecessarily.
2. Go over your receiver with the same kind of thoroughness. Any tubes that even leave you in doubt about their condition should be replaced. More contacts are lost because of inadequacy in receivers than in transmitters.
   If your receiver could profit by the added gain and the improved signal-to-noise ratio of one of the newer

preselectors, it is a fine investment.
If your major problem is lack of selectivity, you may receive a good deal of help from a Q multiplier.
If your receiver is not stable it can be fatal in DX work. The inclusion of VR circuits or some approach to maintaining a fairly constant temperature in the receiver may help. Separate switching which leaves the heaters on at all times is a simple approach to this.

3. Give your antenna system a chance to do its best. Make sure it is the best you can arrange for a given DX band.
If the system is not rotatable, try to orient it toward your favored direction (s). For example, in the central United States a dipole oriented NW/SE will favor both Europe and Australia. The direction of a dipole won't matter tremendously, but take whatever advantage you can get.
Remember that the longer your wire, assuming it and the line are tuned, the better.
Make sure your feed line is the best you can get. Coax may be your easiest approach, but compared to open wire line it is not as efficient.
A tuner is not a necessity, especially if you use coax, but it will more than repay you for your effort and cost in building or securing one.
4. Listen – Listen – Listen. Spend hours on the bands you are interested in just listening. See what bands are open when, and to what parts of the world. Find out what parts of the DX bands will likely be best for you.
For instance, you may find less crowding around 14,075 than around 14,010. For a signal which has its limitations you may do better there even though you hear more DX on the lower frequency.
5. When you are going to call a DX station who is calling CQ, be ready to call the instant he signs. If you drag your foot and hear another station calling him you probably won't call at all. Assume that the same will bé true of others. Get in fast.
Don't call too long. After repeating his call twice and your own twice, break and see if he heard you. If he isn't answering, try two more of each. This is much better than four repetitions to begin with.
6. Calling CQDX. Don't be afraid to do it but don't overdo it. Remember your signal needs an opening more than repetition. Try to find a little gap between signals. Call QRZ once and sign your call. If there is no response call CQDX twice and your call twice and K. No more.
No fancy stuff – no "AR-K" – no "DX pse KKK". In general the DX boys are good operators and they will respond to good practice on your part.
7. Answering. When you get a response keep your first transmission very short. . . . perhaps . . . .
XY9AA De K5PAC – R – GM OM ES TKS CALL UR RST 559 – 559 QTH LITTLE ROCK ARK – NAME JOE – HW – XY9AA DE K5PAC – K
There is little point in repeating what he got the first time, so unless his signal is very weak, keep your repetitions to a minimum. He will want his report, your QTH and your name. The rest can come in later transmissions. Get your first round completed, then get acquainted, if conditions permit, and your friend wants to. If he wants a short QSO, fine, keep it short. Your last transmission can be friendly without wishing "73's, 88's, gud luck, best DX, and gud health" to each member of his family individually.
8. QSL'ing – If either of you really wants a QSL then be prompt about it. If not, "pse QSL" is not an essential part of a QSO. He won't have his feelings hurt if you don't ask him for one. If you actually want it, O. K. If not, why put him to the trouble and expense?

This article is written to convince the ham – maybe *you,* if you've read this far – that fun can be had in the DX aspect of our hobby even without kilowatts and beams.

This is not speculation nor theory. In the past we have had quads and beams and I thoroughly believe in them. But in our present QTH the very best I could come up with was a 100 foot long dipole fed with open line into a home brew tuner. The rig runs about 180 watts CW.

Frankly, I've had a ball working DX on 15 and 20 meter CW. Why not crank up your rig, oil up the key and join me some day soon?

. . . K5PAC

The Short-Vee Antenna

Edward M. Noll, W3FQJ
3510 Limekiln Pike
Chulfont, Pennsylvania 18914

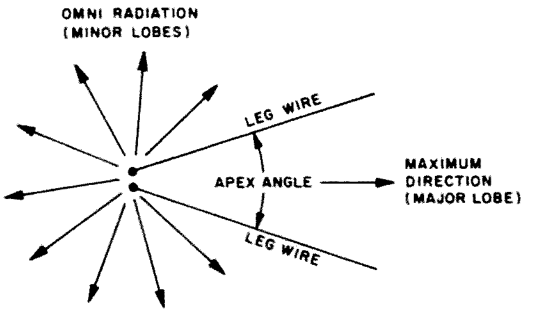

Fig. 1. The Short-Vee Antenna.

The short-vee antenna is an effective fixed-position antenna because of its reasonably omnidirectional pattern plus a broad directional characteristic in one direction. A simple definition for a short-vee antenna would be a vee antenna with a leg length of no greater than 100 feet or no greater than 2½ wavelengths, whichever is the shorter. Angle between the two leg wires would fall between 60 and 100 degrees, **Fig. 1.** If the legs are dimensioned and trimmed carefully, such an antenna requires no tuner and permits direct feed to the coaxial line between antenna and transmitter.

The short horizontal vee antenna should be made resonant on the desired bands. Do so by making certain the legs are an *odd multiple of an electrical quarter wavelength.* Equations for determining odd quarter wavelengths are:

$$1/4 \text{ Wavelength} = 246/f_{mc}$$

$$3/4 \text{ Wavelength} = 738/f_{mc}$$

$$5/4 \text{ Wavelength} = 1230/f_{mc}$$

$$7/4 \text{ Wavelength} = 1722/f_{mc}$$

$$9/4 \text{ Wavelength} = 2214/f_{mc}$$

The practical electrical quarter wavelength of the leg is somewhat shorter than the above formula values. In most instances for a short horizontal vee mounted at least 30 feet above ground, the shortening is approximately 6%. It is advisable to cut the legs long and then cut back slowly to the desired frequency using an antenna noise bridge or swr meter. When using an swr meter it is essential that the meter be placed a *whole multiple of an electrical half wavelength* from the point where the transmission line is connected to the antenna.

Multi-Band Relations

An interesting relationship exists among the odd quarter-wavelength dimensions for various amateur bands. For example the leg length for 5/4 wavelength operation on 15 and 7/4 wavelength operation on 10 is approximately the same. Thus a compromise leg length can be determined that permits optimum operation on both bands, **Fig. 2.** Furthermore an additional leg can be added in conical fashion to obtain an odd quarter wavelength operation on still another band.

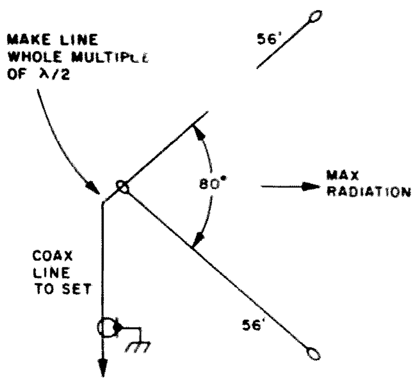

Fig. 2. The 10-15 Short-Vee.

Matching is helped by using a compromise length of transmission line which is a whole multiple of an electrical half wavelength on each band. In so doing the antenna resistance is reflected to the transmitter with little or no reactance. Thus the SWR ratio can be kept below 1.8 to 1 without any tuner at antenna or transmitter. This expedient permits fast band changes.

10-15-20 Short Horizontal Vee

Still another advantage of the short vee antenna is its limited space requirement. A practical version of this antenna style is

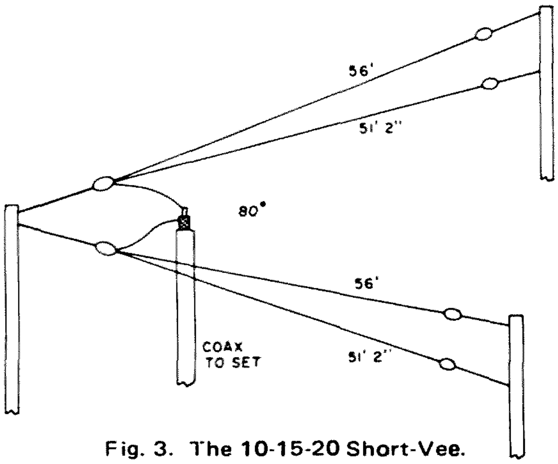

Fig. 3. The 10-15-20 Short-Vee.

given in **Fig. 3**. It serves as a fine antenna on 10-15-20 meter sideband. One pair of legs is cut to 56'. In so doing resonance is established on both the 10 and 15 meter bands. The second pair of legs is cut somewhat shorter to 51'2", operating as a 3/4 wavelength resonant leg on 20 meters.

The two pairs of legs are brought together at the apex and connect to the coaxial transmission line. The legs fan out from this point in conical fashion, **Fig. 3**, and have a separation of approximately 10 feet at the far end.

The apex angle was made 80°. The total length of transmission line from antenna to transmitter can be made any whole multiple of 45 feet. (The 45-foot figure takes into consideration optimum operation on the three bands and the velocity factor of 0.66.)

A line that bisects the small angle of the vee is the direction of maximum radiation. For the short vee antenna it is quite a broad beam. At the same time there are additional lobes that provide omnidirectional radiation as well. Thus the antenna support positions can be selected to obtain maximum radiation in some preferred direction at the same time you can obtain acceptable all-direction radiation as well. It is not a high gain antenna but does give you that extra boost in some preferred direction.

Along the east coast such an antenna could be erected with its maximum direction south toward South America. At the same time it would provide good omnidirectional stateside coverage. If you have a WAS need, the maximum direction can be toward the west. At the same time you would have good north and south coverage. You may wish to beam it toward Europe, always ready for good openings. At the same time you have good stateside coverage.

The Little Wonder

Eddy Shell, W5ZBC
1209 Holiday Place
Bossier City, Louisiana 71010

Every new QTH for the typical ham brings its own antenna problems. Returning to college to pursue additional graduate studies brought the age-old problem of how could I affix an antenna to a college dorm and not come under the watchful eye of the college authorities? The "Little Wonder" and an antenna tuner was the answer to my problem.

The basic idea came from an AFMARS antenna presently being used by some of the Texas members. This antenna is a normal 40-meter dipole with a coil at each end. The coil consists of 197 turns of No. 12 nyclad wire, close wound on a one-inch stock. It is tuned with a 48-inch pigtail which tunes 3311 kHz with a 1:1 SWR, with the ability to have a full-size 40-meter dipole for 7305 and the amateur use as well. (1 inch equals 50 kHz on the pigtail.)

The "Little Wonder" gets its name from the fact that it is a little wonder that the "Little Wonder" works. My first contact on 40 meters was a W3 in Pennsylvania, with a barefoot KWM2 at ten o'clock on a Saturday night and with the "Little Wonder" leaning against a wall in the kitchen location of my "ham shack."

Construction is simple and all parts can be purchased locally:

1 3/4" hard drawn copper tubing 31½" (junk yard, Sears, etc.)

1 3/4" hard drawn copper tubing 43 3/4" (junk yard, etc.)

4 6/32 1" brass bolts and nuts

1 36" oak dowel rod (fir will work, but oak is stronger)

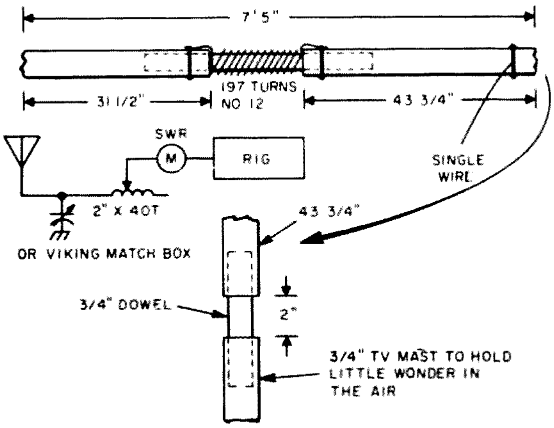
1 roll of plastic tape

1 55 feet of No. 12 nyclad wire (motor rewinding shop)

1 single-wire feedline to run from Little Wonder to antenna tuner...I used 8', 33', and 59' (when it comes into the room it could be hot with *rf*, so use a rubber or plastic coating on this section). I have found the 59' to work best with the Little Wonder about 35' up on top of a TV mast; however, at school the Little Wonder sat on the window ledge—so who knows?

2 3/4" bar stool rubber feet

1 24"x1" plastic water pipe to cover coil after assembly



The Little Wonder

How to construct: Drill a small hole in the wooden dowel 8" from one end. Twelve inches of No. 12 nyclad wire is pushed through the small hole. One person holds the 55 feet of No. 12 tight, and the second person starts turning the dowel rod until 197 turns have been made. A second hole is then drilled, and the other end of the No. 12 wire is put in this hole. Friction and the bend of the wire holds the coil in place. The dowel-coil assembly is pushed into one end of the 43 3/4" tubing, and the other end of the coil is pushed into one end of the 31 3/4" tubing. A 6/32 hole is drilled through the tubing and dowel and a 6/32 bolt makes a mechanical connection of the tubing to the pigtail of the coil. A third hole is drilled opposite the coil in the end of the long tubing, one inch from the end. A 6/32 bolt is placed in this hole for the single-wire feeder to be attached. The over-all length of the Little Wonder is 7'5". Rubber bar-stool feet are then placed over each end of the Little Wonder to keep out the weather, and the coil section is taped for the same reason. Attach your feedline and work the world.

How to tune the "Little Wonder": The best method of tuning the rig is to tune the unit into a 50-ohm load and then connect the antenna tuner. (Do not tune the rig.) The antenna tuner is tuned for 1:1 SWR. (A Viking Match Box will work fine; or make your own.)

How does it work? I am on the air with a lone KWM2 from 3311 kHz to 28 MHz, and without it I'd be QRT for the nine-month period. Trust you will be on the air soon with your own "Little Wonder." ...W5ZBC

Easy Tuning of the Multi-Element Quad Antenna

David S. Traer, W4AZK
625 8th Street, South
Naples, Florida 33940

Perhaps the most perplexing and one of the most controversial problems facing the builder of the multi-element quad is element length or tuning. There are many various articles on quads each having an individual formula for element lengths or method of tuning and matching transmission line to driven element. Basically, there appears to be two methods of approach. Compromise tuning for broad banding or "on the button" tuning for maximum efficiency over a smaller bandwidth.

Since 1958, when I first erected a four element quad, many, many man-hours have been spent making measurements with receivers several miles away, field strength meters, vswr meters, impedance bridges, and grid dip meters. At that time, there were no fiberglass poles, mounting hardware, or any other information available on multi-element quads. It became necessary to find a more or less foolproof method of tuning and matching for maximum energy transfer, with a minimum of effort and with equipment available to the average ham. With these points in mind, I set out to find that method.

Several methods were tried over a period of time. In each case, the vswr over the entire band looked good from the transmitter end—with one exception—the driven element was always reactive. It should be well known that the reactive component of *any* antenna, whether inductive or capacitive, does *not radiate*, in addition, the standing waves along the transmission line are not at the same point as they would be with a pure resistive load mismatched to the transmission line in the same degree although reactance is also measured in ohms. The proximity to surrounding objects does not affect the closed loop of the quad as much as it would a yagi type antenna. Work may be done on the quad much closer to ground level (15-20 feet) if allowance is made for a frequency rise of approximately 25 to 50 kHz at 14 MHz when the antenna is put back to forty feet or higher. Therefore, the quad should be tuned to a lower frequency to eventually come out at the design frequency unless all tuning is done at the final antenna height.

One factor that may be difficult for some, is that all elements must be made accessible. If not accessible from your tower or pole, a temporary 2x4 may be set in the ground high enough to put the boom of the quad at least fifteen feet above ground level. An allowance of 50 kHz should be made at this height. Should the diamond configuration be used, a slightly higher temporary pole would be necessary. From my tests there has been no noticeable difference between the diamond or the square configuration. Some may argue that the two high current points in the diamond configuration, being farther apart, would tend to increase the gain. Theoretically, this may be true, but no measurable difference has been noted here.

Let's take an example of a twenty meter four element quad in the square configuration to be tuned to a design frequency of 14250 kHz. Tuning to be done at a minimum height above ground. First, one must buy, beg, borrow, or build the following equipment: grid dip meter, vswr meter, antenna scope or impedance bridge, and one friend a mile or more away. The station receiver, of course, is also a must. You may use any of the convenient formulas as a beginning because in this case we are not interested in the length of wire as measured in feet and inches, but the results as measured by our equipment. It is always better to have more wire than needed as it is quite easy to cut off any excess. Some use number 10, 12 or 14 solid copper wire, some aluminum clothes line wire, or seven strands of number 20 or 22 plain old antenna wire; which is available at most all wholesale houses. There are now many construction articles on multi-element quads so we will not delve any further into that region.

String the wire and place all elements on

the boom, shorting all loops so that you have completely closed loops. No transmission line is attached as yet. Grid dip the driven element to approximately 14200 kHz. You need not try to be too accurate at this point. Attach your 52 ohm coax to the driven element and to your receiver. Now have your friend transmit a weak signal at 14200 kHz. Adjust the reflector element for a minimum signal from your friend's transmitter. You will note a definite null on the S meter of your receiver as you tune the reflector. A small stub of six to eight inches may be left for final adjustments. Cut off all excess wire, leaving the stub shorted. An electricians "bug" does a fine job as a shorting "bar."

Now let's insert a 52 ohm vswr bridge at the feed point of the driven element. Turn on your exciter at the lowest power possible to get a full-scale reading on your vswr meter. Adjust the driven element length for minimum reflected power. This reading will probably not go to zero reflected power due to the inductive reactance introduced by the reflector. Leaving the vswr meter "as is" at its minimum reading, adjust the first director (the one nearest the driven element) to further reduce the reflected power reading. This may or may not go to 1:1. If not, tune the second director in the same manner. The second director will have less effect than the first director on the reflected power. Proper tuning of the two directors with their capacitive reactance affect on the driven element will cancel the inductive reactance of the reflector leaving as near as possible a pure resistive load at the driven element. Remove the swr bridge and, using the antenna scope or impedance bridge, measure the feed point impedance. Should the swr meter have indicated zero reflected power upon completion of the tuning of all elements, the impedance measurement should have indicated 52 ohms nonreactive on the impedance bridge. In other words, the impedance bridge should null completely at 52 ohms indicating a nonreactive load. In the case of .1 wave length element spacing the impedance should measure about 50 ohms or lower. With .125 to .25 wave length element spacing between 50 to 75 ohms; .2 up to .3 about 75 to 100 ohms. Assuming that your impedance measurement came out around 52 ohms continue with the following. If the impedance is either higher or lower than 52 ohms, it is necessary to now use whatever matching method you prefer. Again an example: assume the driven element swr would not zero after all adjustments, and the measured impedance was in the neighborhood of 100 ohms. A simple quarter wave section of RG11U (75 ohm coax) may be attached to the driven element and all further adjustments made with the swr meter inserted at the junction of the 75 ohm quarter wave matching section and the 52 ohm coaxial line to the transmitter. Repeat the previous adjustments, starting with the reflector and the help of your friend, making only slight adjustments to the reflector as needed. All other adjustments should require only a "touch up." The above procedure is true regardless of element spacing as the phasing of parasitic elements is governed by the length of the elements for a given spacing.

Should the impedance be lower than the transmission line a Gamma or hairpin (Beta) match may easily be used. Refer to such articles or the handbook for adjustments, etc. Should the antenna impedance be larger than the transmission line use a quarter wave matching stub. The quarter wave matching section is preferred because of ease of construction. The Gamma or Beta match may also be used with the driven loop closed, but more time would be required for proper adjustment. The matching section is simply an electrical quarter wave transformer made from coax cable of a different characteristic impedance following as near as possible the result of the formula: The square root of the load impedance times the characteristic impedance of the transmission line. $Z_T = \sqrt{Z_L \times Z_S}$ where Z_T = characteristic impedance of the coax for the quarter wave transformer, Z_L = antenna or load impedance and Z_S = source impedance or the characteristic impedance of your transmission line. Should the load impedance be within a few ohms of 50, the transmission line may be connected directly to the driven element or through a one to one balun.

While the antenna is still lowered, make a bandwidth test with the swr meter at the feed point of the driven element or at the transmission line end of the matching section with low power fed to your transmission line from your exciter. Make swr measurements every 50 kHz and plot the curve on graph paper. Do not become alarmed if the swr rises very sharply at the low end of the 14 MHz band. The CW portion may still be used with the antenna tuned for the phone portion, although the efficiency does diminish. This is "on the button" tuning so the reactance will be negligable over the phone portion of

the band. If you use both phone and CW, it might be well to make the design frequency near center of the band. Likewise, the design frequency may be made in the CW segment if you desire. Getting back to the swr measurements, you will note that *at the antenna*, or the base of the matching section, if one is used, the reflected power is nil across the greater portion of the design frequency, making the *true* swr unit. Next remove the swr meter from the driven element and reconnect the transmission line. There is no need to cut the transmission line to any particular length—just use random length to suit your purpose. Insert the swr meter at the transmitter end next and again make the full swr meter measurements across the band every 50 kHz as previously done with the swr meter at the antenna. Again, plot the curve on graph paper and note the similarity of the curves. Due to a multitude of factors, the transmitter end of the transmission line swr readings will tend to be somewhat lower at the band end extremes.

A dummy load may be substituted for the antenna. Heath's "Cantenna" is a good and inexpensive one. The Waters dummy load power meter is excellent, but more expensive. An *rf* (thermo-couple) ammeter in the transmission line at the transmitter is worth its weight in gold and much more preferable to an in-line swr meter at the same point. Good Western Electric and G.E. *rf* ammeters may be purchased on the surplus market for less than five dollars. After tuning and loading the transmitter to either the dummy load or the antenna there will be no change in transmission line current when switched from one to the other and no retuning of the transmitter should be necessary. This indicates as nearly as possible with available equipment whether your antenna is nonreactive or near pure resistive. If a Bird Model 43 in-line wattmeter or equivalent is available, some interesting overall efficiency measurements may be made. Insert the wattmeter at the antenna feed point and adjust the transmitter to a given plate power input. On all further measurements keep the transmitter adjusted to the same power input. At frequencies near the design frequency the antenna is nonreactive and there is no reflected power and the overall efficiency is indicated. For instance, we adjust the transmitter to 500 watts dc input, the wattmeter indicates no reflected power and forward power reads 300 watts (with grounded grid amplifiers and 100 watts of power output from the exciter, the final amplifier should be adjusted to 360 watts input as the output from the 100 watts from the exciter should appear in the output to the transmission line). The overall efficiency from plate power input to actual power output to the antenna would be 60%. This includes normal transmission line losses, impedance transfer from final amplifier, etc. This percentage may seem high, but is quite attainable with good linear amplifier design and proper matching of transmission line to a resonant antenna. Now tune the transmitter to the same power, but to frequencies at which the antenna is nonresonant. Note the difference in forward power and reflected power. Subtract the reflected power from the forward power and figure the efficiency percentage. Make these same percentage measurements every 50 kHz over the band as was done with the swr curve. That does it! There lies the reason why it is still preferred to have an antenna with less frequency excursion and higher efficiency than one of a compromise nature.

The preceeding procedures are not intended to be the "ultimate" but will afford the "working ham" a less expensive and time-consuming method of getting the most from his multi-element quad antenna. Although the reference is to a four element quad on a thirty foot boom, the same approach may be used with a two or six element quad. The forward gain and F/B ration will be as good if not better than the average when tuned in this method.

Work has been going on for more than three years to broad-band a multi-element quad and yet retain a minimum reactive load over the entire band. Success seems just around the corner, but the last ten years working with the multi-element quad has taken its toll.

The Antennascope — An Effective Tool

W. R. Carruthers, VE3CEA
256 Alexandra Avenue
Waterloo, Ontario, Canada

There are two types of antennas, commercial and amateur. A commercial antenna is generally designed for one frequency, has many acres of ground around it, no obstructions and miles of heavy copper cable buried underground to provide an "effective" ground. These antennas work as designed – very well. The amateur antenna, on the other hand, is just that – an amateur design and construction.

This antenna is subject to all ills, roof tops, buildings, trees, TV masts, house electric wiring, telephone wires and what not. It's a wonder they work at all! But they can be made to work and thousands of amateurs make them work. They make them work by pruning or lengthening the feeder cable and by using an antenna coupler. These are always empirical steps, the "let's cut and try and see what happens" method. How much better it would be, and a time saver too, if we tested our antenna systems electrically and *knew* what was happening and then could take intelligent action to put the whole antenna system into resonance.

This fact is well known – an antenna can only accept power and radiate properly when it is operating at its resonant frequency. This is no problem for the commercial people who operate at one frequency. The amateur, however, wants to "roam the band" and may wish to operate over frequencies hundreds of thousands of cycles wide, even megacycles wide. How can he do this with a fixed antenna system? The answer is, he can't! But he can construct an antenna system for a certain frequency and take the penalty of reduced radiation when he moves far away from it. However this actually works very well, because each amateur has his own particular part of a band in which he likes to operate – and his friends tend to stay there too. On this particular spot, the amateur works diligently to "put out a good signal."

The question arises – how can we make sure our antenna system is radiating well at the particulaf frequency we wish to use? One answer is to use electrical test equipment to show us what is happening on the whole antenna system, which includes the antenna and the feed line.

One of the most useful devices for this purpose is the *rf* bridge, generally called the Antennascope. Basic circuitry and values were described by WA1CCH in the January 1968 issue of 73 Magazine, page 21A. It is a simple device, inexpensive to construct and very effective in results. It is usually powered by a grid dip oscillator. Such bridges should be used at the junction of the feed line and the antenna and will show the resonant frequency of the antenna itself and the radiation resistance at the feed point.

Making such measurement up in the air is a difficult thing for the average amateur and impossible for those whose antennas are supported at the ends. If we are willing, however, to accept a small degradation in results, we can use the *rf* bridge at the station end if we have a half wave, or multiple of a half wave, feed cable. At every half wave point on a feeder cable the voltage and current vectors are in phase, which simply means that the electrical condition seen at the end of the cable is repeated every half wavelength in the cable. We can use the *rf* bridge then, at the station end of the feed line, if we are willing to agree that the results will not be 100% but reasonably close to it. The results will be affected by all the various factors that affect amateur antenna resonance and these effects may give us some peculiar results, but they can be overcome and the final results may be quite valuable to us.

Let me give you an example to illustrate what I'm talking about and to show you how effective the use of the *rf* bridge can be: –

A friend of mine constructed a 40 meter inverted V antenna, held at the feed point 40' up on his beam tower, 66' legs down to supports which held the ends about 8' off the ground. Feed line was 100' of Twin Amphenol cable, velocity factor .68. The antenna was difficult to feed, swr was high, radiation was poor. He asked me to have a

look (electrical) at it. I took my grid dip meter, *rf* bridge and vtvm.

The first thing done was to check the feed line length. 1/2 wave length at 7.1 MHz was 492 x .68/7.1 or 47.1 feet. Two 1/2 wave lengths (to get into the station) would be 94.2 feet.

The first conclusion was that the feed line was 5.8 feet too long.

Next Test No. 1 was made using the *rf* bridge with results as shown in **Fig.** 1, the results being shown in table form and also plotted in graphical form.

7.0	78
7.1	61
7.2	60
7.3	66

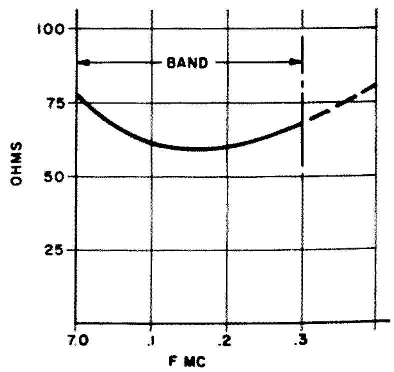

Fig. 5. 85.2' Feedline Test No. 5.

Test No. 6 was with the transmitter (300 watts CW) and antenna coupler connected. There was no trouble in loading and no trouble in balancing the coupler to obtain an swr of 1 to 1 ratio.

The results on the air were interesting,

5/9+ reports to the Eastern half of the U. S. A., 5/8 reports to Germany etc. *Conclusion:* The results shown above are not precise, nor can they be expected to be precise. There are too many unknown factors entering the electrical picture, such as those which required a shortening of the feed line, in this example, to somewhat less than a half wave length. But the bridge showed us the overall picture and suggested what was required to be done. The on-the-air results show that it was giving us a good picture and a result that was very satisfactory for my friend's needs.

Why not construct an *rf* bridge and check you own antenna system? I suggest it will pay off and be very informative to you, showing you what your antenna system looks like electrically and what to do to bring your whole system to the resonant frequency you wish to obtain. . . . VE3CEA

Short Cut to Matching

In building an inexpensive, short space, two element beam for twenty meters, considerable difficulty was met in obtaining an acceptable match from the feed line (RG-58) to the center coil of the driven element (link coupling method...ref. Radio Amateur Handbook, three element beam for twenty meters). The initial set-up is shown in **Fig. 1.**

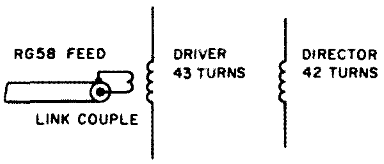

Fig. 1. Link coupling as in the original set up.

After initial tweaking, the best VSWR obtained was a disappointing 3:1. Varying factors such as changing the number of turns, spacing of turns and antenna height resulted only in *increasing* the VSWR.

Further thought and many aggravating trips up and down the ladder resulted in a decision to use an old approach to the problem by going to the "Gamma Match" method in Fig. 2.

The Gamma match was accomplished by:
1. Tying the shield of the RG-58 coax to the center turn #21 of the 43 turn center coil of the driven element and,
2. Connecting the coax center conductor to the 31st turn on the coil. This gave a starting point of 5:1 VSWR.

With a little hint from the handbook, a

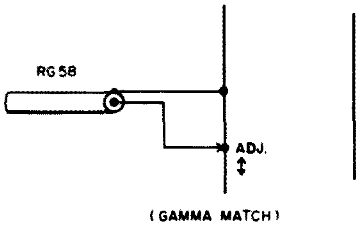

Fig. 2. Using the ever popular "Gamma Match."

140 picofarad capacitor was dug out of the "junk box" and inserted in the coax center conductor line...going to the tap on the coil as in **Fig. 3.**

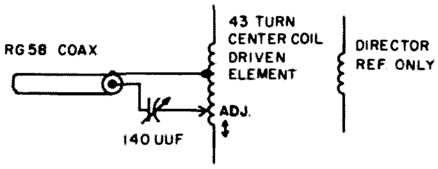

Fig. 3. Adding capacitor for best match.

The capacitor was set at several different positions and minimum of 3:1 was obtained at a max capacity setting. This appeared to be little headway for all the trouble, but past experience pointed to the possibility that the antenna height was a remaining variable not yet changed. A little experimentation with antenna height (more trips to roof) showed best results with it raised just five feet.

A check of the VSWR bridge showed a rewarding 1.5:1 for all our efforts to obtain a match.

Two on Top

Peter A. Lovelock, W6AJZ
235 Montana Avenue
Santa Monica, California 90403

Those of us restricted to using top-loaded verticals on 75-80 meters for fixed station operation, are apt to regret the narrow bandwidth inherent in this type of antenna. So it was with my Hustler 4-BTV, which performs fine over as much as 150 kHz in any selected part of the band, but limited my operation to either SSB or CW for a given adjustment. Since I like to work 80 meter CW DX and also ragchew on 75 meter SSB, there just had to be a better solution than lowering and raising the antenna each time I got a yen for the alternate mode of operation.

There was, and it was as simple as installing two top-loading coils—in my case the Hustler type RM-75.

This was accomplished by fabricating a suitable mounting bracket out of 1"x¼" aluminum stock, as shown in the figure. The two "ears," 45 degrees to the center mounting surface, permit the two coils to be mounted physically 90 degrees to each other, minimizing intercoupling. The bracket is mounted by the center hole to the 3/8"-24 stud atop the 4-BTV, on which a single RM-75 loading coil is normally attached. The stud

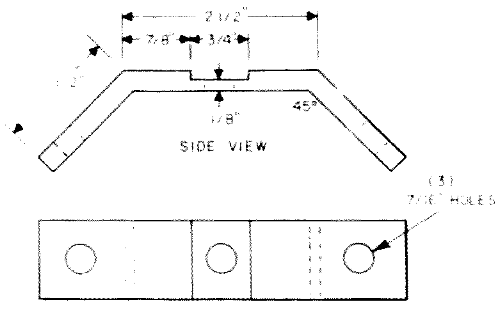

Fig. 1. The mounting bracket for two RM-75 loading coils.

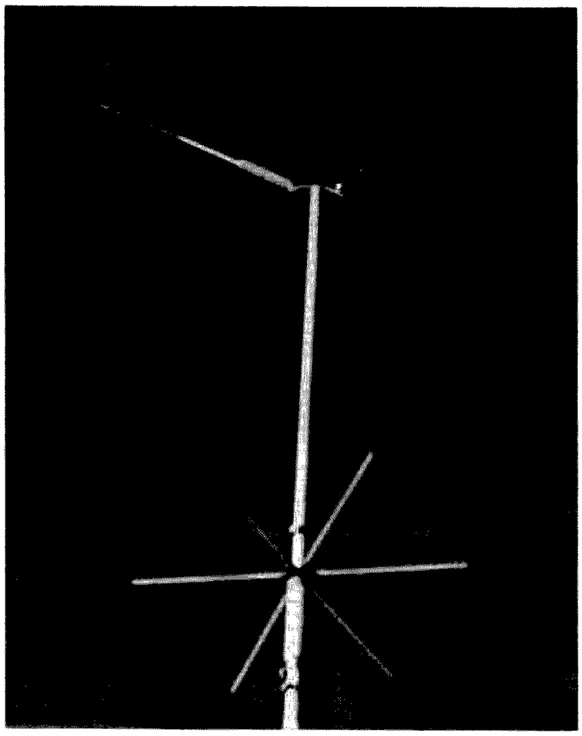
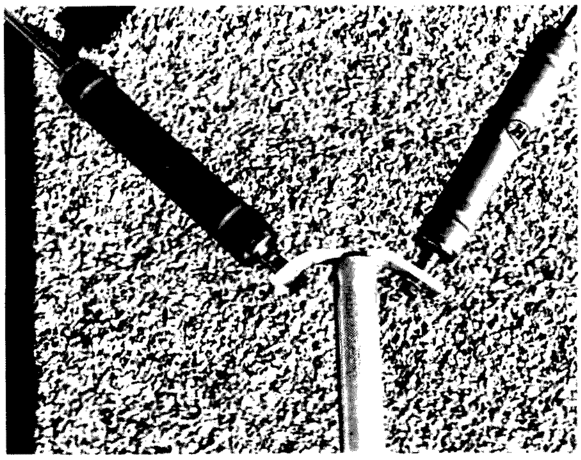


View of the antenna in use.

being only about ¼" long required filing down the bracket thickness to 1/8" at the mounting point, in order to secure the bracket with a 3/8-24 nut. 1"x1/8" stock is also available, but it was felt this would be a bit flimsy, causing the "ears" to flap in a stiff breeze, with detrimental affects on resonance and loading. Anyway, both kinds of stock are to be found in the "Do It Yourself" aluminum rack in well equipped hardware stores. The coils are attached with 3/8-24x½" bolts using washers, plus a split lock-washer to take up the extra bolt length and ensure that the coils won't come loose.

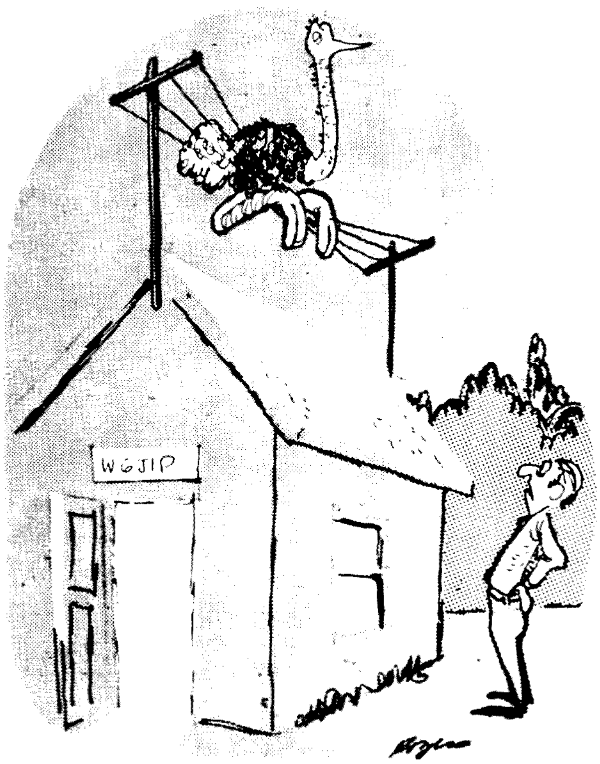
The pictures show the finished product. One coil is resonated by it's whiplet to 3900 kHz and the other to 3550 kHz. The antenna resonates and loads with low SWR at both frequencies with no interaction between the coils, and I can now enjoy operation on my



Mounting details showing the two "ears."

two favorite sections of the band without roof-climbing. The assembly easily withstood recent 55 mph wind gusts.

Of course, this principle can be applied to any similarly top loaded vertical, with a suitably made bracket. Hmmm! If I made a bracket with ears parallel to the mast, I could mount more than two coils, horizontally, and 90 degrees to each other, giving me additional band coverage. Who is going to be first on their block to have "four on top?" or even five? ...W6AJZ



"Blimey! No wonder I'm not copyin'!"

Measuring Antenna Gain

John J. Schultz, W2EEY/1
40 Rossie Street
Mystic, Conn. 06355

Some basic methods are described for measuring antenna gain using a reference gain antenna as well as methods that can be used when a reference antenna is not available. Even for those who do not plan to use the methods described, reading and understanding them will provide a better insight into the meaning of an antenna gain figure. If one likes to experiment with antennas, either building arrays or experimenting with new forms, a continuing problem is how to measure the gain of an antenna. Of course, the proof of any antenna will always remain in how it performs in actual operation. Also, gain is just a number and by itself doesn't convey any information about the overall radiation pattern(except to say that it is formed in some directive manner). Nonetheless, it is often handy to be able to talk about some gain figure for an antenna.

One can estimate gain by using a new antenna in the same mounting position as an antenna of known gain and comparing many signal reports, switching back and forth between the two antennas, to obtain some reasonably meaningful gain figure for the new antenna. The procedure can be rather tedious, however. This article describes various ways by which the gain of an antenna can be more accurately measured, whether one has an antenna of known gain available or not. Because of physical restraints and the interference produced by atmospheric noise, the described methods work best with VHF antennas. However, with care, the methods can be used with well elevated high-frequency antennas. Another way to check the gain capabilities of a proposed high-frequency antenna design would be to first construct a scaled VHF model of the antenna. Such a model is also very useful to study the impedance and matching conditions necessary for best antenna performance.

Basic Method

Fig. 1 illustrates the basic equipment setup which is necessary to measure antenna gain.

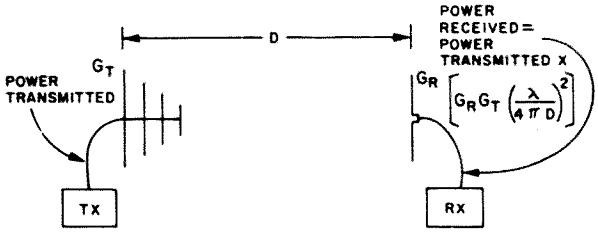


Fig. 1. Basic free-space transmission formula between antennas. Antennas are in the same plane and the transmission line between the equipments and antennas have negligible loss. Loss, if present, can be included as a scaling factor (i.e. a total line loss of 2.5 db will reduce the power received by a factor of .55).

The gain of the antennas and the power transmitted and received are related by the standard transmission equation:

$$P_{transmitted}/P_{received}=G_t G_r\ (\lambda/4\pi\ D)^2$$

G_t and G_r are the numerical values of the gain of the transmitting and receiving antenna, respectively. The term in parenthesis is simply a constant. λ is the operating frequency expressed in meters and D is the distance between the antennas also expressed in meters.

The above equation is true so long as the antennas operate with essentially plane wavefronts. That is, if the antennas are too close there will be an appreciable phase difference between the signal which one antenna receives from the center and the edges of the other antenna. So, for good measurements, D in the above equation should at least be equal to about $2L^2/\lambda$. L is the longest lineal length of the antennas being used and λ is the operating frequency. For instance, if an antenna were to be tested on 2 meters which had a maximum length of 3 meters, or about 10 feet, the test antennas would have to be separated by at least 9 meters, or about 30 feet. Generally, there is no difficulty in meeting the separation requirements unless one is dealing with very large antennas at very low frequencies.

The necessary power measurements can be accomplished in several ways. A wattmeter can be used in the transmitting antenna's

transmission line or the *rf* voltage across the line measured and the power calculated. The line itself should be operating as close to a 1:1 swr ratio as possible. The receiving antenna power can be measured in essentially the same manner or if the gain of the receiver is accurately known, it can act as a power indicating device. Again, the impedances between the antenna, transmission line and receiver input must be correctly matched. Still another method is possible if only the power output of the transmitter can be measured. The transmitting power is adjusted for some convenient reference level on the receiver (receiver avc is off). The receiver "S" meter, if it is the type that functions with the avc disabled, or an audio output meter, if the transmitter is tone modulated, can be used. The transmitter is then connected to the receiver and its output level slowly increased (using an attenuator network or by varying an operating voltage which controls the output power) until the same reference level is obtained. The power level required will be the same as the received power.

If one operates only on a specific VHF band and wishes to construct a sort of "instant reading" gain meter, this can be done by using a dipole as the receiving antenna and placing an *rf* rectifier circuit and meter directly at its terminals. As long as the distance between the transmitting antenna and the receiving reference antenna is kept constant and as long as the input power to the transmitting antenna (of unknown gain) is always the same, the meter can be calibrated directly in terms of antenna gain. It is only necessary to use several antennas at the transmitting end of known gain first in order to establish the calibration of the receiving antenna "gain" meter. Such a device can be a great deal of fun and use during competitions at field days, etc. for the best antenna designs. Aside from the distance and power considerations mentioned, however, the only requirement for the FD "wonder" antennas tested is that they be capable of producing near unity swr in the transmission line to the transmitter. Unless this condition is met, the "gain" meter readings will not be valid in either an absolute or comparative sense. The basis for the calibration of such a meter should become clearer from the following test situations.

Gain Using a Standard Reference Antenna

If one has constructed an antenna of known directivity gain and wishes to determine the gain of an untried antenna design, the setup of Fig. 1 can be used. The transmitter output power and received power are measured and the gain is calculated from the formula previously given, knowing the antenna separation and the operating frequency (using the untried antenna as either the transmitting or receiving antenna). For instance, if the reference antenna used is considered to have a gain of 1(0 db), the original formula can simply be restated as:

$$G=(4\pi\ D/\lambda)^2\ P_{received}/P_{transmitted}$$

Thus, if an antenna were tried on 2 meters at a distance of 10 meters and the power received were 1/10 of a watt for a 10 watt transmitter output, the gain would be:

$$G = (4\pi\ 10/2)^2\ \frac{1/10}{1/10} = 36 = 15.5 \text{ db}$$

This gain is in reference to the gain of the reference antenna (a ½λ dipole, for instance).

In practice, however when one can move the antennas under test about easily, a much more simplified procedure is possible. The transmitter is connected to some available antenna. At a reasonable distance away, the standard or reference antenna is connected to a receiver. The transmitter power output and receiver gain are adjusted to produce some convenient reference level. The transmitter power output is noted. Then, the antenna under test is substituted for the reference antenna. The transmitter power output is readjusted to produce the same reference reading on the receiver. If the test antenna required only 1 watt of transmitter power to produce the same receiver reference level as when 10 watts were used with the reference antenna, the gain of the test antenna is simply 10 ÷ 1 or 10, which also happens to be 10 db. Remember that the numerical power ratio must be converted using a db power curve for db gain expression. Again, the antenna gains obtained by this method will all be referenced to the assumed unity gain (0 db) of the reference antenna.

Gain of Two Identical Test Antennas

Suppose that one had two identical antennas and did not know the gain of either nor had any reference antenna of known gain available. Surprisingly enough, the gain of the test antenna design can still be easily found. If the gain of both antennas in the test setup shown in Fig. 1 is the same, the original gain formula is re-arranged in the form:

$$G=4\pi\ D/\lambda \qquad P_{received}/P_{transmitted}$$

The received power and transmitted power can be measured with some specific antenna separation and the formula will yield the gain

of either antenna (as a numerical value, not in db). If the received power cannot be measured directly, the receiver can be used just to establish a reference level and the transmitter connected alternatively to one of the test antennas and then directly to the receiver to establish a power ratio that can be used in the formula.

The gain figure obtained from this procedure is mathematically related to a so-called isotropic antenna which radiates equally in all directions. A ½λ dipole antenna when used with this procedure should show a gain of slightly over 2 db—since it does concentrate its radiation broadside to the line of the antenna. Thus, if more complicated antennas are checked by this method the gain figure obtained must be reduced by 2 db if a comparison is desired with other antenna gain figures which use a ½λ dipole as a reference.

This procedure is frequently used to establish the gain of reference or standard antennas against which test antennas can be compared.

Gain of Three Different Test Antennas

Suppose that one had a group of three antennas none of which appear to have the same gain and no reference gain antenna is available to compare them against. By a variation of the previous procedure, the gain of all three antennas can still be established.

The antennas are arranged as shown in **Fig. 2**. The distances between them need not be equal but is assumed so to simplify this description. Using the basic transmission formula and when station 1 transmitts, the following formulas are obtained, each of which produces a simple number when the measured values are inserted.

$G_1 G_2 = (4\pi D/\lambda)^2 P_{rec.\ 2}/P_{trans.\ 1} = A$

$G_1 G_3 = (4\pi D/\lambda)^2 P_{rec.\ 3}/P_{trans.\ 1} = B$

Next station 2 transmits and the following relationship is determined:

$G_2 G_3 = (4\pi D/\lambda)^2 P_{rec.\ 3}/P_{trans.\ 2} = C$

Since three constants and three interrelated gains are concerned, the gain of each antenna can be found:

$G_1 = AB/C \quad G_2 = AC/B \quad G_3 = BC/A$

Again, the gains will be in numerical form and must be converted to db values. Also, the gains will be referenced to a theoretical isotropic antenna and must be reduced by 2 db for comparison to gains related to a ½λ dipole.

Precautions

The basic transmission formula used actually derives from optic equations, although it is the standard radio transmission formula. It

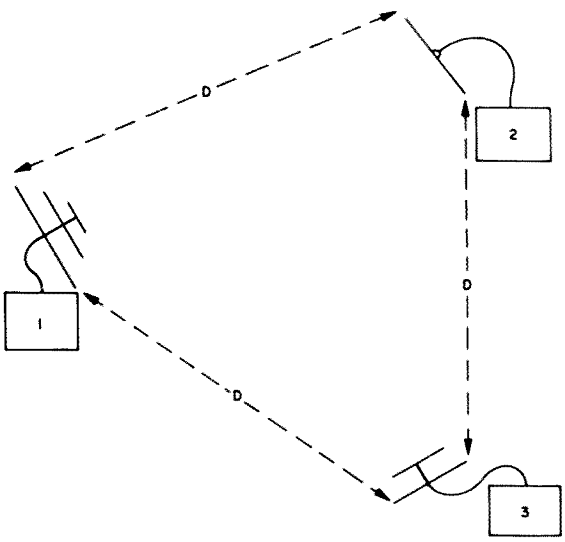

Fig. 2. As described in the text, the gain of three dissimilar antennas may each be found although the gain of none of the antennas is known. D, distance between antennas, need not be equal. The only requirement is that all the antennas have the same polarization.

does not take into account any other signals being present except the transmitted one in space. At high enough frequencies, this condition is reached with radio transmissions but at lower frequencies an antenna will receive noise signals as well as the desired signal. Therefore, allowance must be made, if possible, for the error caused by noise reception. If the received power levels are high compared to the received noise level, the noise effect may not be significant. At great distances and with low power levels meaningful results cannot be obtained.

Some other general precautions are:

1. Both antennas must be oriented for maximum signal before measurements are made. It can happen that maximum radiation does not coincide with the geometric center of an antenna.
2. The formula is based on line-of-sight transmission. Reflections, including those from inadequate antenna height, should be avoided.
3. The antennas must be separated sufficiently to produce a plane wave.
4. Correct impedance matches must exist throughout the transmitting and receiving terminals.
5. If the receiver is used as a power level indicating device, its gain must be reasonably stable or should be frequently checked. It must be operated in its linear range without overloading and with its avc off.

The use of a low power transmitter whose power output can be readily varied was as-

sumed. A signal generator of sufficient output power can also be used. If one uses a method such that connection of the transmitter to the receiver for reference level setting is not necessary, a transmitter of fixed power output of any level can be used.

Summary

When commercial laboratories make gain measurements using some of the methods described they take elaborate precautions to avoid effects that will alter true gain readings. However, even with simple equipment—even the regular station transmitter and receiver in many cases—meaningful results can be obtained.

Even if one does not measure the gain of any antennas, the material in this article should give a better insight to many amateurs as to how the gain figure for an antenna is determined. Particularly, it should clarify how antenna gain is always related to some *reference.* Thus, unless one knows the reference, one can easily read good-sounding but not really useful gain figures for some antennas.

Finally, it should be appreciated that gain is *only* a numeric and not the only meaningful characteristic of an antenna, although too to gain figures. Other factors such as the vertical and horizontal radiation pattern forms, front-to-back ratio, impedance, bandwidth, etc. are just as important and, indeed, in some applications more significant for best communication than gain. ...W2EEY/1

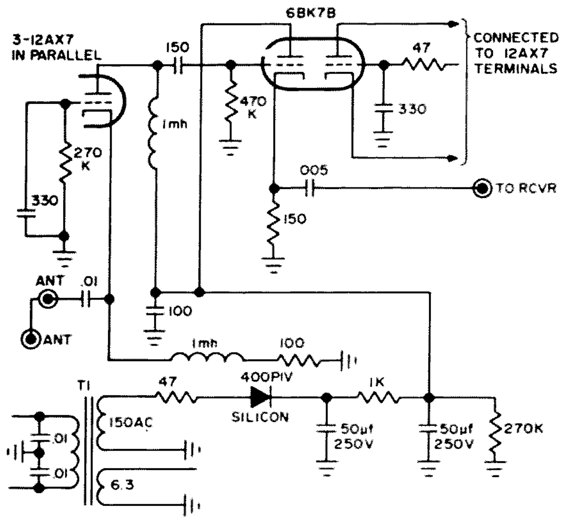

Fig. 1. A different TR Switch.

A Different TR Switch

The TR Switch described in May 1963 *73 Magazine* on pages 12 and 14 has undergone a metamorphosis or change for the better. While in some areas of the country the grounded grid configuration will function well, it behooves the amateur in a metropolitan area, especially where there are several marine, coastal, point to point commercial stations operating, to use a different circuit. The *rf* chokes, especially the one in the cathode of the grounded grid tubes, have a self resonant frequency and lo and behold, commercial stations can be heard in the background. Weakly, but still there. No amount of decoupling will eliminate them. Different values of chokes can be used, but then a sacrifice in gain on the amateur frequencies results.

The most satisfactory circuitry tried to date uses a cascode *rf* stage lightly coupled to the transmission line, and a cathode follower output to match the receiver input impedance. A tube rectifier is used as an *rf* rectifier to provide dc voltage bias on transmit times. There is no time constant—it is instantaneous, for CW, in order for fast break-in. When using SSB, the bias holds long enough between syllables so that the receiver stays blocked as long as you keep talking. When receiving, the rectifier has no effect, unless a kw station next door fires up. In that case, he will create enough bias in the TR switch to prevent overload of the set. It will lower the gain of your receiver, but without this effect, you would have another kind of trouble. You would probably go to the other end of the band or change bands. It will be apparent to the experienced constructor that this unit can be used as a tuneable preselector merely by substituting the 1 mh L_2 *rf* choke with suitable tuned circuitry. M. C. Smith, W6GMC

QRP - A New World to Conquer

Arthur Child, W6TYP
1485 Pine Street #407
San Francisco, Cal. 94109

Amateur radio has been getting more expensive and more complicated for those interested in building their own gear. It may come as a surprise to discover there are some hams who are finding ham radio simpler and more challenging. These unusual hams are the QRP operators, trying to use lower and lower powers to cover greater and greater ranges. For the QRP'ers a single transistor rates as a powerful transmitter, and communications may be maintained at power input levels so low they are hard to measure. Could you use your signal generator for a transmitter? If it is stable enough, yes! But it would be too complicated for a really convenient QRP rig.

QRP achievements are a real eye-opener. See Fig. 1. Powers much less than typical flashlight levels can achieve communication over hundreds or thousands of miles. Transmitter cost is small; there are no high voltages, and antenna systems typically range from Joysticks to carefully installed dipoles. The emphasis is on operating skill and on patience which gets you on the right frequency at the right time. At QRP levels you do not blast the opposition, you wait until he fades or quits. Or you learn to hear through him, and somewhere in there you become a real radio operator. In the QRP world the quality of the man is more important than the quality of the rig. The emphasis is on operating skill and patience. That is a refreshing change and this new perspective has proven reliably popular.

QSO	Time	Freq. MHz	Mw Input	Range Miles	Mi./ W. eq.
W8UUJ/6, Cal.	4 pm	7.015	33	273	8,200
WB2GFQ, N.J.	12 pm	7.142	50	2565	51,300
W7OE, Wash.	9 am	7.015	100	680	6,800
WA9DEU, Ill.	7 pm	7.015	500	1840	3,680
WA8JXQ, Ohio	8 pm	7.142	500	2110	4,220

All QSO's by calling CQ. None were arranged.

Fig. 1. Log excerpts. Every one of these contacts is above the basic 1,000 miles per watt achievement that gets you going in QRP.

A world-wide organization of QRP'ers has developed. Membership is about 3,000 radio amateurs, living in 50 countries. It may be these people are the very best radio operators in the world, since they routinely try to achieve effective communication at power levels comparable to the *unwanted* emissions from much amateur gear and far below that from some commercial broadcast transmitters. And, they succeed, setting records of thousands of miles on milliwatts of power. For instance, you can talk from San Francisco, California to South River, New Jersey, on 50 milliwatts input. It's an established record.

Art Child, W6TYP, writes he has been trying to make contact with QRP'ers in Japan and ZL land. Some entries from his log appear in Fig. 1. Previous results indicate he'll succeed since he is using his big rig for this project. It runs 500 milliwatts. Some other of Art's achievements are a 2½ mile QSO on 12 microwatts for 200,000 miles per watt and a 354 mile QSO on 354 microwatts for one million miles per watt.

QRP Recipe

Interested? Find a good receiver, or make up something from scratch. A good possibility appears in the 3-tube superhet described in the October 1968 issue of 73 Magazine. Perhaps you could do something with the regenerative detector circuit appearing in the same issue. And while you're working over the receiver problem (which will probably cost more than anything else) get a letter off to the QRP Club's corresponding secretary for additional information on activities and memberships. That goes to F. Behrman, K7LNS, 3425 S.E. King Road, Milwaukee, Oregon.

Next step is a good antenna. There is plenty of information around about antenna design and construction, and QRP work simply makes quality more emphatically necessary. The difference from a normal antenna will appear in quality, rather than expense, and this is largely a matter of care and workmanship. Installing and tuning a really effective antenna will require some test gear, and recent issues of 73 Magazine can offer material to help you out. A simple antenna bridge may do more for you than an swr meter, since you

may not have enough *rf* available to energize the meter. For many ideas see 73's special Antenna issue, May 1968.

As you get this set up you can think about your transmitter. Crystal control is preferred, so that once other QRP'ers know where your signal typically appears on their receiver dials, there will not be tuning questions with very weak signals. And you will appreciate the same reliability in their signals. On 40 meters the best frequencies are 7.015 or 7.142 MHz.

A typical circuit appears in Fig. 2. Few components could be pared out of this one. You will want to do some experimenting with this circuit, so start with a good high-frequency silicon or germanium transistor, use 1K ohms in the emitter circuit, and try 82K ohms in the base circuit. Place an mF as emitter by-pass, and a few picofarads in the base circuit to control feedback. C3 and L1 are tuned to the operating frequency and if L1 is a piece of Airdux, the antenna tap is easily moved up or down. Start with the tap close to ground, since antenna loading reduces *rf* available for feedback and at some point will cause poor keying. Listen to the signal on your receiver.

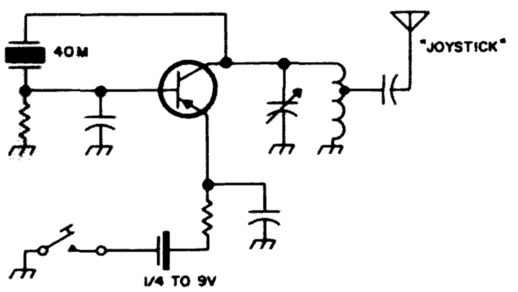

Fig. 2. This could be the simplest transmitter circuit ever published in 73 Magazine. Inexpensive, too. The "Joystick" antenna is in the same room, eliminating coupler, transmission line, etc., and tapping up the coil increases loading. When you can get out with this, you are learning to be a really good operator.

International's printed-circuit crystal oscillator can also do a nice job as a transmitter. The printed-circuit construction is very neat, and the kit sets you back $2.35 postpaid. See October issue of 73 again, page 5. The crystal runs another $3.75, specify the frequency. And another dollar should get the *rf* well started toward the antenna.

Finishing up the rig, you put a TR switch in the antenna system somewhere and you are in business. The transmitter frequency is located during tests by tuning the receiver to pick up the transmitter—you don't do this with a kilowatt! with key down. The receiver would probably not be harmed if you fed the transmitter's entire output into its front end and in some station setups you might have a little difficulty finding the transmitter signal, but a clip lead will help you out. Better be careful on principle, though, if your receiver has a solid-state front end.

Finally, start calling. It will take patience. After all, the air is full of high-power operators, some of whom tend to ignore signals under S9 or so. Yours will be one of these.

Soon you will learn to operate odd hours. Perhaps the honorable art of ragchewing will appeal to you, again. And you will wake up sometimes in the middle of the night thinking about a QSO, and why not? You are likely to become an early bird, early to bed and early to rise. This is said to offer valuable benefits unrelated to ham radio, and it also gives you a fantastically quiet band to operate in. The signals seem to sound different at this time of day, just before the sun is coming up. It is an experience you shouldn't miss.

QRP Performance and Records

Communications at QRP show a very strong dependence upon propagation conditions. On 40 meters, for instance, the best results are achieved late at night, as you might expect. But at QRP you cannot ignore the facts and vagaries of propagation conditions. They just jump right out at you, and you will soon become interested in the fluctuating conditions of the ham bands.

Once contact is made at, say, high power of 500 milliwatts then you can start ragchewing. QRP contacts, unlike DX contacts, may go on for extended periods as you and your contact crank down the power again and again, trying to achieve effective communication with the smallest transmitter power input.

When your log shows you can get a 1,000 miles per watt certificate from the QRP Club you are starting to achieve results. But the records are very much better than that, and recent work includes contacts on 40 meters ranging from 325 miles at noon to 2565 miles at 11:00 p.m., local time. On 50 milliwatts. That's better than 50,000 miles per watt. One million miles per watt is possible and has been achieved. Such records are unusual and definitely worth working for. Aside from the fact they offer an interesting challenge of the very best kind, you are sure to meet unusual and interesting people along the way. Don't miss the opportunity to enjoy QRP operation.

...W6TYP

The Galaxy GT-550 Transceiver

Peter A. Lovelock, W6AJZ
235 Montana Avenue
Santa Monica, California 90403

A decade or so ago transceivers came into being primarily for mobile application. Almost as an afterthought manufacturers made available AC power supplies for alternate fixed station use. Subsequent trends have caused transceivers to evolve in complexity (and size) to become complete, single package stations; some with an array of controls calculated to send a computer programmer into frenzied rapture. But have you ever tried to fit one of these integrated jobs under the dash of a Mustang? Or juggle a bank of knobs never designed for compatible freeway operation?

When Galaxy Electronics introduced their model III and V transceivers, it was obvious they had the mobile ham in mind as evidenced by functionally located controls, a tuning dial on the left side for optimum driver manipulation, and dimensions ideally suited to underdash installation. And a lot of fellows discovered that, with an outstanding receiver circuit and 300 watts PEP input, the Galaxys did an excellent job in the shack. Their feather weight and easy mobile mount made dual usage a snap.

The model V Mk 2, besides increasing input to 400 watts PEP, also added features for the CW operator such as sidetone, and plug-in options for semi-break in and a 300 Hz receiver filter. The V Mk 3 incorporated final tubes capable of 500 watts PEP.

Galaxy also developed a line of accessories for full fixed station flexibility with their transceivers, while retaining the inherent simplicity, desirable for mobiling, in the basic transceiver. This also permitted the buyer the choice of paying only for those features required for his particular mode of operation.

Having used a Galaxy V Mk 2, shared mobile and fixed, for a couple of years, I could testify to its performance, stability and rugged construction on the highway, while 108 countries and a lot of good CW work with an apartment trap vertical left little to be desired at home. With this experience, it was difficult to conceive that much room was left for improvement...that was, until at the recent SAROC convention, I witnessed the unveiling of the Galaxy GT-550.

Gone was the former, somewhat austere, front panel – to be replaced with contemporary styling guaranteed to gain living-room acceptance from the most discriminating XYL (mine). While keeping the same well-arranged controls, now with skirted knobs, a new single-scale, 500 kHz dial eliminates the second scale that formerly reversed frequency direction for tuning 20 meters. Now CW and phone segments have the same dial relationship on all bands – a pleasure for CW DX bandhoppers like me. The familiar two-speed tuning knob is supplanted by a massive, 2½" diameter, single speed knob with plastic insert finger spinner. The spinner permits traversing the entire 500 kHz range quicker, and more easily than the wrist switching action required with the old two speed control. The 72:1 ratio tuning is velvet smooth and the kingsize knob gives finger-tip precision with no discernable backlash, even when using my narrow bandwidth CW filter.

Black on white tuning and S-meter dials, indirectly lighted behind rectangular windows, make for easy reading and enhance the new styling.

A study of the schematic proved that the GT-550 is based upon the tried and true cir-

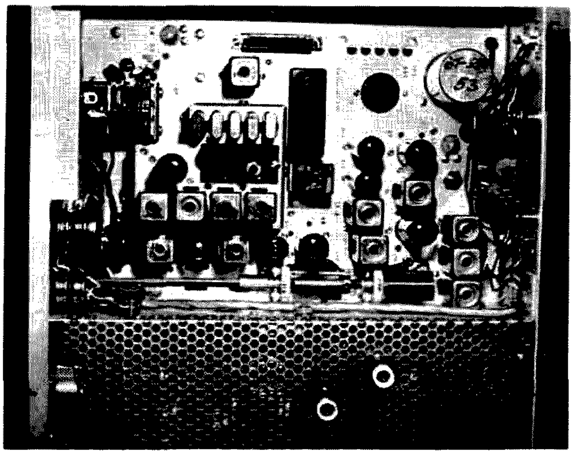
cuitry developed through the earlier Galaxy series, with numerous significant improvements. The new parallel 6LB6 finals, together with a redesigned driver stage, provide improved linearity and ALC action for 550 watts PEP input. On CW the final operates at 360 watts input with reduced screen voltage for maximum tube life. As in previous Galaxys, the TUNE mode may also be used for CW operation, with input power continuously variable by the MIC/DRIVE control, from a fraction of 1 watt up to 250 watts.

Many circuit changes noted indicate continuing effort for peak performance in both receive and transmit modes. The already sensitive receiver circuit has been made even more so on the GT-550, as is particularly apparent on the ten meter band. This is where so many receivers show a drop-off in performance, but the GT-550 S+N/N ratio is extremely good. An added crystal for vfo hetrodyning has eliminated the need for that separate scale on 20 meters. Improved high and low voltage regulation includes provision for accurately adjusting the regulated 12 vdc used for the vfo, and also brought out to a rear panel jack for accessory operation. ALC control voltage is also brought to a rear jack for use with a linear amplifier, and is handy for plugging in a vtvm to observe where alc action begins relative to plate current peaks when setting the MIC gain control. Another added jack for the external vfo accessory, obviates running coax through a rear panel hole to a chassis jack, as in earlier Galaxy models.

Those operators who periodically check alignment to maintain top performance, will be glad to know that mechanical design of the GT-550 has made all alignment procedures possible from the chassis topside. No need to remove the bottom plate and balance the unit precariously on one side. In fact, the GT-550 can be completely aligned in its normal operating position by merely removing the top cover. Even RC 'swamp' circuits required for accurate adjustment of double tuned transformers, are built in. Just shorting a chassis test point to ground with a screwdriver swamps one winding while the other is being peaked. A vtvm chassis mounted test jack aids in alignment.

The bank of five band-hetrodyning crystals are mounted atop the chassis for accessibility—a convenience for operators wanting to substitute crystals for extended 10 meter or MARS frequencies.

The single piece top cover can be lifted



Interior view of the GT-550 Transceiver.

off, or slid back on the unit, for easy access by removing four screws. New design permits removing the final compartment shield without having to take off the bottom plate. The same basic dimensional configuration maintains the GT-550's adaptability to mobile or fixed installations, and the appearance is equally pleasing in both.

Like its predecessors, the GT-550 comes with an individual frequency drift calibration chart, as measured at the factory prior to shipment. Mine indicated a maximum warm-up drift of 140 Hz in the first 20 minutes, after which stability remained within a range of 10 Hz for the 40 minute balance of the test period. This degree of stability has been borne out in actual operation.

Checking the actual power output with a Waters Dummy Load Wattmeter Model 334, the following maximum readings were obtained when loaded according to instructions:

TUNE mode: 160 watts, CW mode: 280 watts.

SSB mode (1 kHz sinewave to MIC input): 400 watts.

The GT-550 can be powered either by the AC-400, a new heavy duty supply with switch selection for 115-230 vac, 50-60 Hz input, and solid state rectification; or the G1000DC supply for 12 vdc mobile installations.

All in all, the GT-550 offers a lot of transceiver at moderate price. Add plug-in options for the CW man, and a line of accessories including plug-in transistorized 25 kHz calibrator (for those new band limits); complimentary styled external VFO, 2 kw PEP Linear Amp., Hybrid Phone Patch with tape recorder facilities, speaker console that accommodates the AC-400 supply, and an RF Console that switch selects up to five antennas plus dummy load—with built-in forward/re-

flected wattmeter...and you have building blocks for a home station tailored to your needs, around a state-of-the-art transceiver ideally suited for mobiling.

Technical Specifications

Frequency Coverage—3.5-4.0; 7.0-7.5; 14.0-14.5; 21.0-21.5; 28.0-28.5; and 28.5-29.0 MHz with crystals supplied. Additional ten meter and MARS frequencies with accessory crystals.

Dial Calibration—5 kHz increments. 500 kHz range, with single linear scale—over 12 inches of bandspread. 72:1 ratio vernier tuning.

Operation Modes—Selectable USB-LSB, suppressed carrier. PTT or VOX (with optional accessory). Shifted carrier CW, manual or semi-break in (with vox accessory). Built in sidetone.

Transmitter—SSB input: 550 watts PEP. CW input: 360 watts. Carrier suppression -45 db. Unwanted sideband suppression, better than -55 db. Antenna load impedance, adjustable 40-100 ohms. Hi-Z microphone input for -50/60 db level.

Receiver—Sensitivity better than ½ μV for 10 db S+N/N ratio. Double action, fast attack delayed release, audio derived agc. Nominal 1 watt audio output to 8 ohm external speaker.

General—Crystal lattice filter on transmit and receive provides 2.1 kHz selectivity with 1.8:1 shape factor. Audio response 300-2, 400 Hz at -6 db points on receive and transmit. Dimensions approximately 7½" H x 11¼" W x 13-3/4" D. Weight approximately 13 lbs.

Novice Antenna

One of the problems the Novice has is the antenna. Many times it is a problem because of lack of knowledge, space or funds. Here is an 80 meter vertical which solves all the problems.

Most of the parts can be scrounged. You will need 17 feet 4 inches of ½" thin wall electrical conduit; a 5-foot piece of 2x2 inch lumber; a 4-foot length of tubing to use as a supporting mast; a coil, and some hardware.

Bolt the conduit to the 2x2, overlapping about 2 feet. The top of the loading coil (in this case Illumitronics #2010—#16 wire, 2½" diameter, 10 turns per inch) is bolted to the conduit and the bottom of the coil is bolted to the wood. The supporting mast is then bolted to the other end of the 2x2 and sunk into the ground. 50 ohm coax is used to feed this antenna. The shield of the coax is connected to the mast, and the center conductor is temporarily fitted with an alligator clip for ease in tapping the coil.

Using an swr indicator, tap the coil at the point where the lowest swr is found. In my case, this was about 23 turns. The swr was still about 2:1. To bring it down, cut two radials ¼ wavelength long and connect to the point where the coax shield is connected to the mast. The radials can be buried. Pruning the coax length will also help bring down the swr at the transmitter.

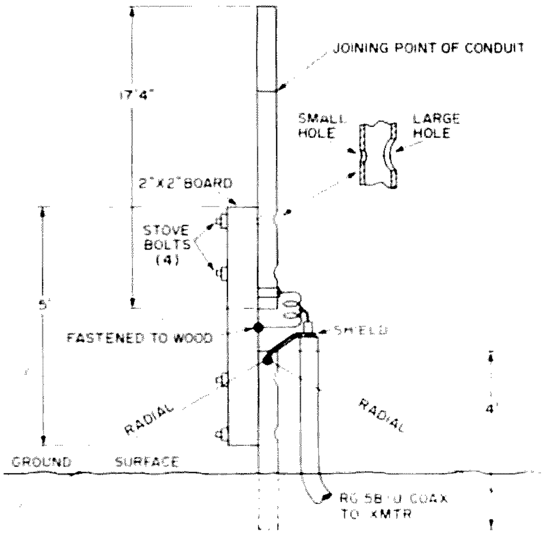

Fig. 1. Variable is mounted on the 1¼" TV mast.

Now that you are thoroughly confused, look at **Fig. 1** and you will see the arrangement.

Wayne Jinske, WA9SSH

The Super SS

Clifford Klinert
520 Division Street
National City, Calif. 92050

A Real Life True Adventure Story

It is Saturday afternoon. I return home from work slightly tired, but refreshed in the thought of the weekend ahead. It doesn't happen often, and I really look forward to a little relaxation with my favorite hobby. I feel deep pride to be a member of the ARRL, the organization that arranges these contests. There is nothing I enjoy more than operating my station with the best of my speed and skill competing with others doing the same.

To the shack. Check it out. Twenty meter beam. Forty meter dipole. I turn on the transmitter. Oscillator. Drive. Plate tuning. 300 mils. Good. I turn on the receiver. Let's see who I clobbered. Nobody heard me. Good. Coffee. Pencils. Log. Paper. Clock. Check. Let's go.

I reach for the receiver dial, the hard black knob feels smooth in my fingers. Smoothly as velvet the pointer moves up the scale. The QRN ebbs and flows like waves on the beach, now softly sliding across the sand. Up through the noise pops a signal. I gently nudge the antenna trimmer until the rhythmic beat of a steady fist rings clear as a bell.

CQ SS. It's a VE. Must turn the rotor. Reach for the control. Click-click-click-uummmh. The lights dim. Pull the leads apart. No good. Pull the line cord.

Slightly despondent, I pace the few steps to the door and begin the painful ascent up the tower along the wall. With a mighty effort I pull myself to the roof. The sun is down now and a light mist hangs over the city softly filtering the strange glow from the mercury vapor lights on the street. Above arches the twenty meter beam like a parasol with its elements reaching into the darkness. Thin wisps of smoke curl from the bottom of the rotor, almost masked by the veil of the fog.

Up the tower. Good thing it's strong. Welded it myself. Know it's right. At the top. I wrap my legs around the tower and grip the boom. Pull. Harder. Gears frozen. Pull harder. Crack! Small piece of tower hits the roof. Hold tight to boom. Boom bending. Crack again. Here comes the rotator. Metal fatigue. Gotta work on that. Falling. Here comes a guy wire. Rotator catches. Hanging on. Snap! Cheap guy wire. Buy it new next time. Here comes top of tower

Almost gently the top of the tower rotates downward, bending at the center and picking up speed. Now, nearing the roof, I hold tightly and watch its sickening descent. The top of the tower shears off the corner of the roof like a knife slicing butter. Now I carefully make my way down the remains of the tower, nothing but a grotesque tangle of twisted metal.

Wow! Splinters and roofing. Down to the ground. Forty meter dipole still OK. Shack OK inside. Only slight hole in roof. Bandswitch. I call CQ SS. Plate meter pins. Lights dim. Final's shorted. Power switch. Reach inside. Pull shielding off finals. It hit me. Wall falling away. Floor hits me. Everything black. Feel. Hard floor. Still alive. Reach for drawer. Flashlight.

The small sharp beam of the flashlight questioningly probes the darkness, tracing a cloud of thick grey smoke. I carefully sort through the tangle of wires and unplug the transmitter. Painfully, I limp outside and recycle the circuit breaker. I force myself back and view the damage. The power switch is welded on by the high current. The silicon diodes, now completely ruined, are blisteringly hot. Now the receiver once again warms up and returns to life.

QRN. On my frequency. Now calling me. A ZL. Pretty good signal. I grasp the receiver with both hands. Wires breaking off. Over my head. Heavy. Push hard. Across the room. Into the wall. Plaster and wood splinters. Wow! Tear up ARRL certificate. On the floor.

Once again I make the trip across the room. I move more slowly now with the seething forces inside me subsiding. I gently pull the light switch and close the door. I stroll toward the house carefully stepping over an object in the path. Some smoke still diffuses through the hole in the wall into the still purity of the night. The sky is now perfectly clear with the stars flashing like gold sequins on black velvet.

Quiet. To the house. Open the door. Wife. Still awake waiting. Arms around my neck. Soft. She speaks.

"Have a good contest?"

Yes. ...WB6BIH

A Novel Approach to Feeding and Tuning the Three-Band Boomless Quad

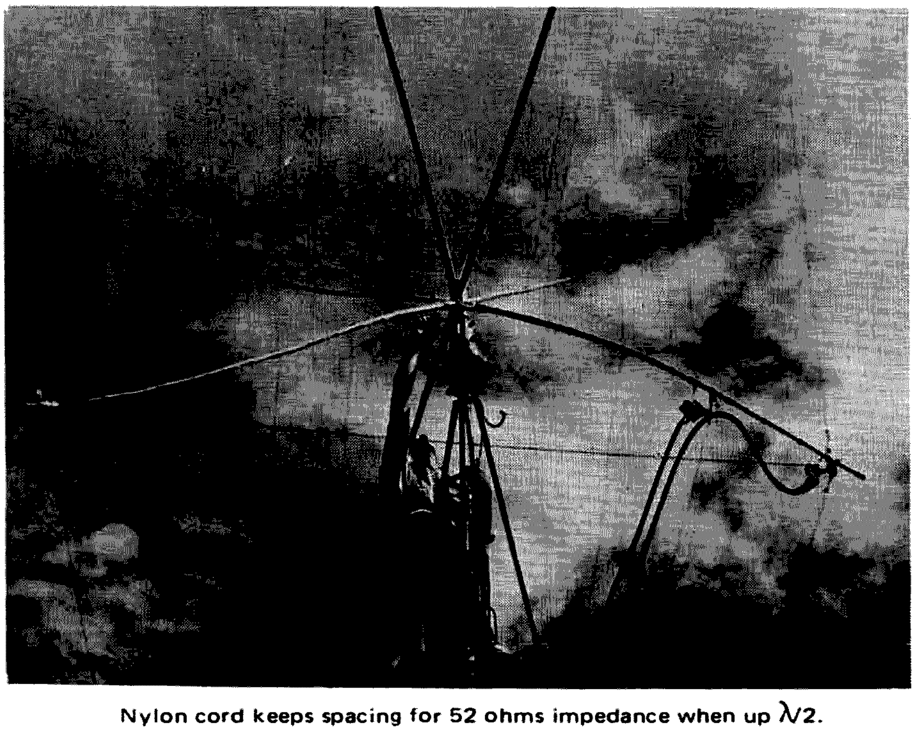
W. E. Rabenhorst, WA4VWY
1715 29th Avenue
Vero Beach, Florida 32960
Member of the Bar,
U.S. Supreme Court

Although I learned two codes at age 13, one of 13 children on a farm in Wisconsin, and received my discharge from the Signal Corps in Washington, D. C., in November 1912, I did not obtain my General license until March 1948 and my Class A in March 1950.

One day I worked W3JXH in nearby Maryland and was invited to drive the few miles to see a quad antenna, my first. It turned out to be a 10-15 two-element all-metal job and only a few feet above ground, surrounded by buildings and overhanging trees, and enclosed inside a high steel fence. The owner claimed fine dx contacts.

I then went about building a 15-meter all-metal quad with both elements grounded on the upper boom. Although this quad had excellent F/B ratio, the band remained dead for several days, so the 15-meter job was taken down and a 20-meter quad of similar type built to take its place. It was initially fed at only four feet three inches from the ground. The first contact was with K3UIG, a "Government Employee" nine miles across town. The QSL which arrived two days later bore the name Barry Goldwater, with a beautiful color photo of the Nation's Capitol building. Other contacts were mostly beyond the Mississippi River and Central America and, when the band was either just opening or closing, generally quad-antenna stations answered. Diamond-shape quads are said to have a lower angle of radiation. Before leaving Washington, D. C., I gave this quad to W3YAE.

After arriving in Florida I decided to experiment with quads of the more conventional square, all wire type. Twelve different quads were built and torn down – boom, short boom and boomless. No. 13, the



Nylon cord keeps spacing for 52 ohms impedance when up λ/2.

present one, a boomless quad, was designed by W4TZ, across town, who had two composite aluminum spiders electrically welded, one of which was assembled and erected on the tower by me (age 76) without any help and without use of a safety belt. The decision not to use the safety belt loaned by W4TZ may sound a bit queer. Some 65 or 70 years ago a group at a Wisconsin family reunion witnessed a dog attempting to scale a picket gate, as he had done many times before. He caught the ring of his collar on a picket and hung there helplessly. Hanging by a safety belt, should my foot slip, might temporarily knock the breath out of an old man! However, I strongly recommend the use of safety belt, especially to you younger fellows with still many years ahead of you.

The accompanying photo shows the composite spider to have an aluminum plate at the center with eight short aluminum radials electrically welded thereto at an angle so that the spacing between the 20-meter driven element and its reflector is 6 feet 10 inches, with a corresponding lesser spacing for the 15- and 10-meter elements. This spacing, with the reflector properly tuned at a sufficient height above ground, resulted in a unity SWR when fed with RG/8-U or RG/58-U. The Quad handbook says that if the quad is below a certain height the impedance drops to one-half.

Square quads are normally fed at the center of the lower horizontal wire of the driven element. Since dipoles fed at the center are said to be a reasonably good match for 72-ohm feeders, and an inverted "V" having a 90-degree angle is said to be a good match for 52-ohm RG/8-U, I chose to feed my square, boomless quad at one lower corner for the following additional reasons: 1) the feeder may be fastened to the radial, thereby lessening sway in wind; 2) no need to pull the center of the driven element upward, out of shape and out of true with the reflector; and 3) it seemed to be more convenient to attach the SWR bridge at this point during tuning procedure. Believe it or not, it worked!

Fig. 1 shows construction of tuning coil at the corresponding (but opposite) corner of the reflector. Note the absence of long tuning "stubs" in the photo, which not only distort the plane at the current node, but also tend to affect the adjacent bands. The tuning coil was formed by winding antenna wire on a 7/8-inch dowel and, when released, forms approximately a one-inch diameter

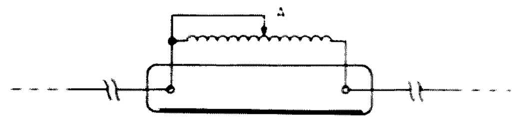


Fig. 1. Tuning Coil. When SWR bridge approaches unit, the clip A is removed and the short lead soldered to the turn. A change in capacity and configuration of coil might affect SWR if the shorted portion of coil were to be removed, more so, on 10 meters than on 20 and 15. Less turns are needed on 15 and 10 meters.

coil. This coil was then spread slightly and fastened to the ends of a somewhat shorter, thin insulator so that the outer edges of the turns are spread sufficiently to permit clipping a short piece of wire to a single turn without shorting an adjacent turn. Although less turns are needed for 20 meters, I started with a 26-turn coil because of the length of the insulator on hand and made the initial tap at the center turn, thereby shorting out one half of the coil.

Tuning was accomplished with a low power SWR bridge at the feed point where it could be clearly read at that short distance, and at a time when the band appeared to be dead or "out" so as to reduce chances of interference. Remember, I had no assistance and had to ascend and descend the ladder and tower (more than once!) to accomplish the tuning. A short piece of vinyl from the coax had previously been slipped over the clip to prevent *rf* burn when changing taps on coil. The coil being at the radial, it was easy to steady it during the tuning process by grasping the radial with the other hand. It was only necessary to go a turn or two either side of the original tap to arrive at the desired swr. The clip was then removed and the wire soldered in place, a 50-foot extension cord having furnished the required power for soldering gun. After removing the bridge and replacing it near the rig, it was only necessary to make a two-foot change in the feeder length to secure a like SWR reading of 1 to 1 at that location.

I used a 3-cent, home-made balun, following the general instructions for a 1 to 1 balun in August 1964 QST. The core is about 2 inches of ferrite obtained from a discarded BC loopstick, and wound with the necessary turns of No. 16 copper enamelled wire. It is not sealed, but merely taped. Weather? Reports from contacts do not materially differ, whether during dry weather or rain.

W4TZ uses a common feeder for the three bands, and a quarter-wave sleeve balun

at each of the respective feed points, and the other ends of the quarter wave fastened to the common feeder. His watt-meter shows remarkably satisfactory swr.

Incidentally, either bamboo poles or fiber-glass radials may be slipped into the short, slotted aluminum arms of the spider and a non-skid hose clamp secures the radial.

The width of the tower shown in the photo was such that only one foot could be placed at a time on any cross-member. The other leg and one arm were draped around the tower during the erection of the quad, and the free hand was used to put the thing in place. The necessary tools had previously been placed in accessible pockets. The tower was not of the tilt type.

If an old man can assemble, erect and tune this boomless three-band quad without assistance, you younger fellers should be able to obtain similar satisfactory results.

Recently a station reported an S-8 signal off the back of the quad, but 20 over S-9 from the front. Not bad!

It is understood that fiber-glass radials now come in four-foot sections whose ends slip readily into each other, and are mailable by parcel post. At this point it may be of interest that I and my supervisor inaugurated the Parcel Post System in 1913 after trials at Chicago, St. Louis and New York to obtain size, weight and cost data.

If and when I can secure an aluminum welder (electric), I may be able to furnish this composite spider (and radials). That, however, was not the intended goal when this No. 13 boomless quad was designed.

Acknowledgement is hereby made to W4TZ for his assistance in designing the angle of the spider and having the first two prototypes made; also to C. D. Bently for photograph.

. . . WA4VWY

Mosley 80M Dipole Kit

The DIV-80 Dipole antenna is a complete package designed as a regular or inverted vee dipole for 80–10M. It is rated at 2 KW PEP or 1 KW on AM or CW. The Kit includes 140' of Copperweld wire, a Mosley Dipole Connector (DPC-1) and two ceramic end insulators. The Kit includes simple instructions for pruning the antenna to the co-rect length for the part of the band in which operation is desired. It might be worth a mention that many stations using inverted vee antennas on 80 meters are working DX with ease.

To Patch or Not To Patch

Dale E. Coy, W5LHG
3322 49th Loop
Sandia Base, New Mexico 87116

For 20 years, hams have argued about phone patches. After a generation of discussion, the matter is about to be settled. The phone patch may become another "standard" appliance in the ham shack. But not without some trials and tribulations.

The idea of the phone patch is almost as old as the radio and the telephone. Military services have used "radio-wire integration," and the phone companies have long distance radio links. Telephones in private automobiles are obviously phone patches. Amateur equipment has included phone patches for years, too. A number of respected companies make them, and articles have appeared from time to time in CQ and 73 magazines. Why, then, is there so much confusion? The problems and arguments start with the "tariffs" filed by the telephone companies. For most practical purposes, a tariff can be considered as a law. Almost every telephone book prints a tariff which bothers the amateur with a phone patch—"No equipment, apparatus, circuit or device not furnished by the telephone company shall be attached to or connected with the facilities furnished by the telephone company...." The arguments caused by this tariff are shown by the attitudes of the amateur radio magazines and the ARRL. CQ magazine has continued to print phone patch articles. 73 magazine has been rejecting articles until a decision is made by FCC. And the ARRL has maintained the opinion that all phone patches are illegal. There is no mention of phone patches in "The Radio Amateur's Handbook," and the only mention of telephones warns the amateur to contact the telephone company if telephone interference occurs.

The official attitude of the telephone companies has been that phone patches were not legal. As a practical matter, though, "Mother Bell" has realized that amateur use of phone patches actually increases telephone traffic. Of course, there were objections if the amateur tried to connect his own extension phone in the shack and to install the wiring himself (thus avoiding extension phone charges). Poorly designed or operated patches have sometimes (though seldom) brought a knock on the door. But as a practical matter, the ham who asks the phone company to install an extension phone in the ham shack has usually found that the phone installer is quite willing to assist in hooking up the phone patch. At least, that way, it is done correctly. The fact is that hams have rarely (if ever) been prosecuted for operating a good phone patch.

The possibility has always existed, though, that the amateur might be doing something illegal. This possibility has resulted in a great reluctance to use phone patches. Some recent decisions of the FCC may change the tariffs, and could result in expanded use of the phone patch.

The FCC can, if it wishes, review telephone company tariffs and set aside those tariffs it does not approve. In 1956, the FCC's "Hush-A-Phone" decision caused a clarification of tariffs to allow use of devices which are not electrically connected to the phone. The legal wording of the decision caused many lawyers to feel that amateur phone patches would also be considered legal, although they are usually connected to the phone lines. After 12 years, in June, 1968, the FCC has clarified its position in a decision on the "Carterfone" case. The most significant portions of the FCC opinion are printed below.

> We hold that the tariff is unreasonable in that it prohibits the use of inter-connecting devices which do not adversely affect the telephone system....Our conclusion here is that a customer desiring to use an inter-connecting device to improve the utility to him of both the telephone system and a private radio system should be able to do so so long as the inter-connection does not adversely affect the telephone company's operations or the telephone system's utility for others. A Tariff which prevents this is unreasonable....We are not holding that the telephone companies may not prevent the use of devices which actually cause harm or that they may not set up reasonable standards to be met by inter-connection devices. These remedies are appropriate. We believe they are also adequate to fully protect the system.

The opinion set aside the tariffs preventing connections to the telephone system, and

declared that they "are and have since their inception been unreasonable, unlawful, and unreasonably discriminatory..." The "Carterfone" decision, then, declares that phone patches are (and have always been) legal, if they do not harm the telephone equipment.

This decision, and tariffs effective January 1, 1969, (more on this later) have caused the ARRL to change its mind and allow phone patches as "legal" traffic. But, as might be expected, the telephone company does not appreciate the FCC decision. "Mother Bell" will lose a lot of money if customers go elsewhere for Teletype interface, facsimile, and data transmission equipment. The telephone company has appealed the decision—or at least a part of it—in a New York appeals court. This action is mostly intended to prevent suits by Carter and others, and doesn't appear to be intended to overturn the entire FCC decision.

It seems that AT&T intends to get the most mileage from the part of the FCC decision which says "We are not holding that the telephone companies may not prevent the use of devices which actually cause harm or...set up reasonable standards to be met..." Under this part of the decision, AT&T *could* file a tariff requiring inspection and approval of any connected device (including phone patches) by the local telephone company. This procedure has been in effect for some time to allow customer use of the customer's own telephone instrument as an extension. Inspection of the extra or "decorator" phones often costs $10 or more. Checking a phone patch would probably cost so much, or take so much paperwork, that the average ham wouldn't bother.

The move which prompted ARRL's acceptance of phone patches was the AT&T tariff (FCC) Number 263, which was effective January 1, 1969. This tariff has, in turn, been "reproduced" by the telephone operating companies and filed with state regulating agencies. The provisions quoted below are from Mountain States Telephone and Telegraph Co. General Exchange Tariff for New Mexico, Section 17, Part 12, effective January 6, 1969. The FCC tariff, and other local tariffs, are almost identical.

> Connection with customer-provided Equipment and Facilities....Certain customer-provided voice transmitting and/or receiving terminal equipment may be connected to the Exchange and Long Distance Message Telecommunications networks at the regulations, rates, and charges specified herein. ...May be connected through a Telephone Company network control signaling unit at the following rates and charges: Connecting arrangement, for connection of customer-provided voice transmitting and/or receiving equipment (including switchhook control key), each (QKT) $ .50 monthly. Maintenance service call resulting from customer-provided equipment, each $10.

This "QKT" connecting arrangement is rather simple. The "network control signaling unit" is a slightly-modified telephone instrument. A special switchhook key is provided. One of the buttons in the telephone cradle may be lifted and locked into place, which will cut out the telephone transmitter element and switch in a special set of coils hooked to the "QKT" jack.

The Electronic Industries Association has called the "network control signaling unit" provision of the tariff "common carrier featherbedding." The provision means that the customer cannot provide his own means of dialing, impedance matching, or answering of calls. While this provision will not bother most hams, some of us like to provide our own dialing arrangements. In addition, no matter how good your patch is technically, *even if it is better than telephone company equipment* (and many are), the company won't trust it.

The 50 cent monthly charge seems reasonable, although it does add up to $6 a year. Of course, a one-time installation charge is added (about $6.50), as well as the monthly cost for the extension phone if the one in the shack isn't the only one in the house.

The "maintenance service call" provision of the tariff means that any trouble caused by your phone patch will cost you $10. If you complain about your telephone service, and the cause is really your patch, it's your $10. If it's the fault of the telephone company, there is no charge. And, of course, if your patch causes problems which bring an unasked-for knock at the door, this will also cost you.

The "QKT" jack provides access to a 900-ohm matching coil within the telephone. For phone-patch purposes, you can treat this just like a telephone line, except that you cannot use it for dialing, and you cannot "answer" or "hang up" using this line. The 900-ohm figure probably comes as a surprise to you, as it did to me. For years, we have been thinking that line impedance was 600 ohms, and carefully designing our patches to work into that figure. The old, open-wire telephone lines *were* 600 ohms. It came as a great shock to me to learn that almost every sub-

scriber line in the United States now has a nominal 900-ohm impedance. This fact will probably be a surprise to most phone patch manufacturers, also. However, the 600-ohm equipment has worked well in the past.

There are other restrictions on what you can feed to the jack supplied by the telephone company.

> ...Power of the signal at the central office (must) not exceed 12 db below 1 milliwatt averaged over any 3 second interval....The power of the signal which may be applied by the customer-provided equipment to the Telephone Company interface located on the customer's premises will be specified for each type of connecting arrangement but in no case shall it exceed one milliwatt.

In other words, you are not allowed to over-drive the telephone company lines. This is a reasonable provision, and should be the basis for providing a meter on your phone patch, although most patches don't have meters. It is not too likely that your patch will provide more than a legal signal. If it does, the "network control signaling unit" has *some* built-in compensation. Of course, the telephone company *could* specify an unreasonably low input level. Line loss can be as high as 10 db. Be suspicious in this area, but don't leave yourself open to that $10 charge.

> The power in the band 3995 to 4005 Hertz shall be at least 18 db below the limit (that is, 18 db below the 12 db below 1 milliwatt at the central office)....The power in the band 4,000 Hertz to 10,000 Hertz shall not exceed 16 db below 1 milliwatt....10,000 Hertz to 25,000 Hertz–24 db below... 25,000 Hertz to 40,000 Hertz–36 db below ...above 40,000 Hertz–50 db below...

These figures give the "low-pass" filter requirements which your phone patch must meet. They should not cause any difficulty.

> To prevent interruption...(the) signal (will) at no time have energy solely in the 2450 to 2750 Hertz band. If signal power is in (the) band, it must not exceed the power present at the same time in the 800 to 2450 Hertz band.

This rather simple restriction is the reason for the occasional unexplained disconnection of an apparently-good phone-patch circuit. The telephone companies use special signals in the 2450-2750 band which are the equivalent of a "hang up" command, and the call is cut off. An occasional hetrodyne at the wrong frequency can cause this problem, but there is not much you can do about it.

Other Methods

There is one other way to accomplish a phone patch, and it can be done at a saving. Section 20 of the tariff provides restrictions on "Inductive or Acoustic Coupline," which can be used *without charge.* I suspect that there will be quite a bit of amateur development effort toward developing inductive or acoustic phone patches. The restrictions are as follows: "...Network control signaling shall be performed by equipment furnished, installed, and maintained by the Telephone Company.

In other words, you have to have a telephone. No fair just inductively coupling the patch to the telephone company lines. "...Connection is made externally to a Telephone Company network control signaling unit."

You can't put part of the patch inside the telephone. The inductive coupler or acoustic arrangement must be outside the phone.

> ...Equipment must comply with the following minimum network protection criteria: ...The power of the signal which is applied by the customer-provided equipment to the network control signaling unit located on the customer's premises be limited so that the signal power at the output of the network control signaling unit (i.e. at the input to the telephone company line) does not exceed 9 db below 1 milliwatt when averaged over any three second interval....(and)....(frequency/power limits).

Notice that the signal power restriction is 9 db below 1 mw *at the line input,* rather than at the central office. If your line happens to be among the worst, your signal could be 19 db down at the central office, rather than the 12 db allowed for an electrically (QKT) connected system. This is rather restrictive, and again industry has objected. The frequency/power limits are the same as listed before, except that they are referred to the minus 9 db figure.

Now What?

With phone patches now legal, the amateur "fraternity" should take some positive action. Each of us with a phone patch must make sure that the patch is operated properly and that it is not harming the telephone equipment.

Since a tariff now exists for customer-provided equipment, the telephone companies can no longer turn a blind eye on phone patches. The cost is really very reasonable, and the peace of mind is worth it. Call the local company and get "legal" yourself.

Since the ARRL now recognizes phone patches, we should urge the ARRL and any other interested amateur groups to present the amateur views on this subject to the FCC

and the state regulating agencies. I feel that a well-designed phone patch should not be subjected to the additional restrictions of a "network control signaling unit," and should be allowed to provide dialing, answering, and control functions if properly constructed. If you support this view, write the ARRL. The FCC sometimes listens to the voice of amateur radio. Possibly, a good quality phone patch could be used as a supporting exhibit. In any case, make your opinions known.

The phone patch is a useful piece of equipment, and now it's legal. Let's keep it that way.

...W5LHG

Will Amateur Radio Win the Technology Race?

Ham radio is becoming extremely technical, what with SSB, VHF, UHF, SHF, Moonbounce, Pulse, Masers, Lasers, etc. Unless the convictions of most amateur radio operators change drastically, technology may destroy ham radio.

As an 18-year old electronics engineering student, I have been observing the more experienced operators above the age of thirty, most of whom have become content to possess their general license and just chew the rag. Few will admit their stagnation, but only a handful of "go-getters" are advancing ham radio technically. And even fewer are keeping up with the advancement. Many SSB operators really do not even understand the technique of SSB generation!

Just take a look at the bands above 50 MHz. Only on the frequencies where commercial equipment is available are there any large-scale operations. The majority of ham radio is not willing to explore the upper region, either due to lack of knowledge or lack of initiative.

Now I am not professing to be an electronics genius, but I am not content to pass the test and take a rest! After four to eight years of college, I plan extensive study of radio technology, far beyond what is expected of the average ham.

What I am advocating, however, is not for all amateurs to study college courses. This is too much to expect. But at least be able to understand your present rig. Try to keep pace with the moderate theory. Maybe, if you keep active, both on electronics theory and on the air, you'll be a better ham. Remember, amateur radio is not CB. We are supposed to lead in technology and experimentation, not follow.

Roy C. Pollitt, WA3IID

A Direct-Reading SWR Indicator

J. M. Prosser, K3WRW
P. O. Box 68
New Market, Maryland 21774

The direct reading swr indicator.

The device described here was conceived as a result of my somewhat frustrating experience in tuning an antenna matching circuit. The procedure usually recommended goes something like the following:

1. Tune up the transmitter into a dummy load of the proper impedance.
2. Remove the dummy load and connect the antenna matching unit to the transmitter through the SWR bridge.
3. With SWR bridge set to forward (FWD) position and transmitter energized, set the meter pointer to full scale.
4. Switch the SWR bridge to reflected (REF) position, and adjust antenna matching unit for minimum reading on the meter.

This sounds simple enough, but all too often the REF reading is decreasing because the transmitter output is decreasing as a result of mismatch. To guard against such a condition after an adjustment is made, the SWR bridge must be set to FWD, the meter adjusted to full scale, and the SWR bridge again switched to REF. Hopefully, the SWR has been decreased, but this is not always the case. What is involved, then, is a repetitive cycle of setting the meter to full scale in the FWD position, switching the bridge to REF, making an adjustment to decrease the reading, and then checking the result. This can get pretty frustrating after a while. There should be an easier way, and there is.

What is needed is a way to compare the forward and reflected readings continuously while making the adjustments to the matching unit. Of course this could be done by using two meters to show forward and reflected power simultaneously, and adjusting everything to maximize the reading on the forward meter while minimizing the reading on the reflected meter. I feel that the device described here is even simpler to use and it requires only one meter. Basically, it is a voltage comparator, as shown in **Fig. 1**. The meter should have a high impedance for best results. This circuit has some limitations.

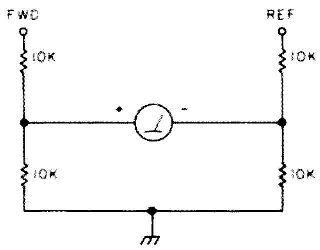

Fig. 1. A simple voltage comparator. This circuit has some limitations since a false swr reading may result depending on power.

For example, there is no way to determine what the SWR is; that is, high power with high SWR may give the same reading as lower power with low SWR. This limitation is removed in the circuit of **Fig. 2**. The SWR calibrations on the usual SWR indicator are computed from the following equation: SWR = (FWD + REF) / (FWD - REF). As an example, if we let 10 represent a full scale reading, and adjust to full scale with the bridge set to FWD, and switch to REF and get a half-scale reading (5) the SWR is (10 + 5) / (10 - 5) = 3.0. For the same case, using the circuit of **Fig. 2**, the voltage at point F will be twice that at point R. If we now set R1 to its midpoint, the meter will read zero. It now becomes obvious that R1

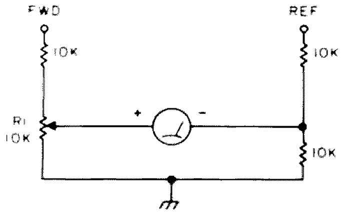

Fig. 2. The direct reading swr indicator which gives more accurate results.

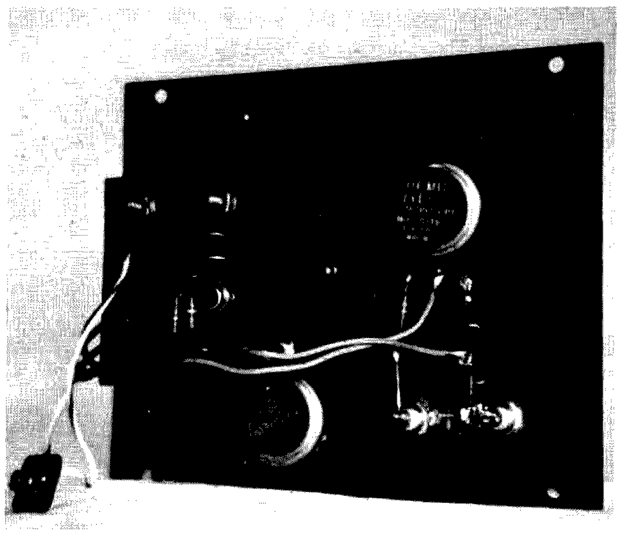
can be equipped with a dial calibrated in SWR; i.e., the midpoint would correspond to SWR = 3.0. The dial can be calibrated by use of an ohmmeter as follows:

SWR	Resistance (from ground end)
1.0	0
1.2	909
1.5	2000
2.0	3333
3.0	5000
5.0	6667
10.0	8182
20.0	9048
00	10000

The meter used in my version is a 1 MA movement with a transistor amplifier similar to that described in January 1966 issue of 73. The meter amplifier was built on an etched circuit board for mounting directly to the meter terminals. The meter scale is arbitrarily calibrated with zero in the center. A resistor (82K) is used in series with the base lead to prevent changes in the zero-set when R1 is varied. My bridge has a positive output. If the one to be used has a negative output, the meter should, of course, be reversed.

The use of this device is extremely simple. The transmitter is first tuned up using the dummy load. The antenna matching unit is then connected to the transmitter through the SWR bridge. The meter is set to zero, and the transmitter is then energized. Adjusting R1 to bring the meter back to zero will then enable the SWR to be read from R1's dial. After this, any adjustment of the antenna matching unit which causes a more positive meter reading on the SWR indicator is in the right direction. The *amount* of increase in meter reading is a relative matter, depending not only on the SWR but also on the transmitter power. If the operator desires to determine the new (improved) SWR, he need only adjust R1 to bring the meter back to zero and read off the SWR from the calibrated dial.

Of course, the use of the direct-reading SWR indicator is not limited to tuning antenna matching networks. It can be used by anyone who would prefer its simplified SWR readout. If R1 is set to a higher SWR than that actually existing, a positive meter reading results, and the transmitter can be tuned for maximum output by maximizing the reading, just as in using the conventional indicator in the FWD position. ...K3WRW



A look at the interior. Obviously a simple device to build.

Asymmetrically Feeding Long-Wire Antennas

John J. Schultz, W2EEY/1
40 Rossie Street
Mystic, Connecticut 06355

Changing the location of the feed-point on long-wire antennas can make major changes in the radiation pattern—changes that can be used advantageously when the antenna placement must remain fixed.

Illustrative patterns and methods to match and determine the feed point impedance are presented.

Many amateurs have room enough to erect an antenna that runs only in a specific direction. This situation may be due to points being available to support the antenna in only specific locations, or an antenna may have to be run in a specific direction because of obstacles, safety requirements, etc. When a wire antenna (doublet feed with a coaxial or a resonant line) is used on the lower frequency bands, the height in wavelengths is normally not very great, and the antenna radiation pattern is very broad—such that stations can almost be worked equally well whether situated "broadside" or "off the ends" of the antenna. On higher frequency bands, however, due to the increased electrical height and length of the antenna, the radiation pattern becomes quite sharp, both in the horizontal and vertical planes. On bands such as 20 meters and lower, one may have room enough to run an antenna that is several wavelengths long. But, if the line of the antenna must lie in a direction that coincides with the direction to a desired area, the signal radiated to that area will be many db below what it would be if a simple ½ λ dipole could be erected at right angles to the long antenna.

Assuming that one can only run a wire antenna in a fixed direction, one has to find some means of changing the radiation pattern to favor a desired area other than that of physically reorienting the antenna. One method that can be used is to asymmetrically feed the antenna. There is some change in radiation pattern when a wire antenna is either center or end fed, but the change is not extremely great (when end-fed, the radiation tends to be emphasized towards the unfed end). However, asymmetrically feeding a long antenna can produce a variety of tailored radiation patterns. One can't completely rotate the radiation pattern to any desired direction, but it is possible to at least develop useful radiation in directions that aren't covered by a symmetrically fed antenna or to produce a reduction in the response of the antenna towards a direction from which interference originates.

Effect of Asymmetrical Feed

The horizontal radiation pattern of a horizontally placed wire antenna is determined by the current/phase relationships in various sections of the antenna. When the antenna is symmetrically fed, a symmetrical horizontal radiation pattern results, such as is shown in **Fig. 1**. The cloverleaf-type pattern shown in **Fig. 1** results whenever the total antenna length is more than about 3/4 λ; otherwise, the main radiation is broadside to the line of the antenna. As the antenna is made longer in terms of wavelength, the lobes of the cloverleaf pattern become sharper and have a peak intensity at an angle closer to the line of the antenna. Sharp secondary responses also appear, some of which can have the radiated intensity of a dipole at its maximum orientation.

If one had a 3 λ long antenna which produced the horizontal radiation pattern shown by the solid line in **Fig. 1** and found that this pattern produced poor results in certain directions, **Fig. 2** shows some of the solutions

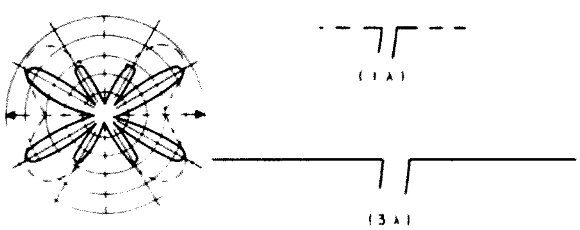


Fig. 1. The horizontal pattern of a 1λ long symmetrically fed antenna (dotted lines) and a 3λ long symmetrical antenna.

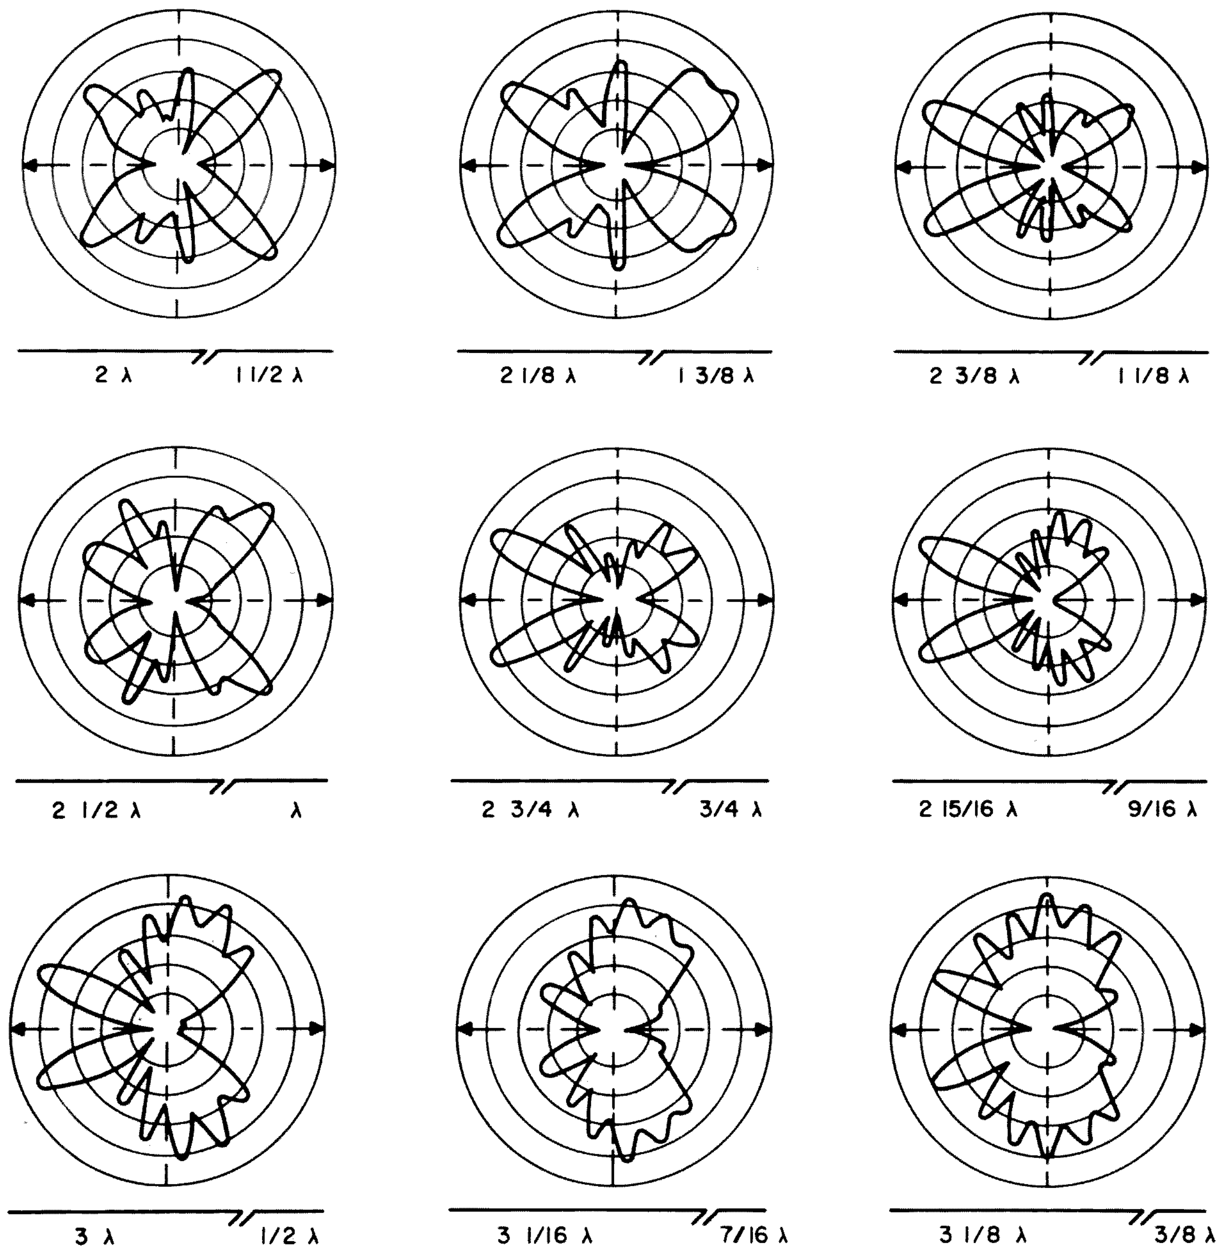

Fig. 2. Changes in the horizontal pattern are illustrated as the total length of an antenna (3½λ) is held constant, but the feed-point is moved gradually toward the right.

that asymmetrical feed can offer. Note that the horizontal patterns in **Fig. 2** are produced as the total antenna length remains constant and the feed point is moved towards the right. The same form patterns but with mirror responses would be produced if the feed point were moved toward the left.

Particular patterns deserve note, and it should be apparent as one studies the diagrams that in some cases very little change is required in antenna dimensions to produce significant changes in the pattern.

As the short side of the antenna is decreased slightly in length, some broadening of the main lobes occurs and the sharp second-responses are more filled in. The peak response of the main lobes changes from about 20 degrees to 45 degrees as measured from the line of the antenna. As the short side is reduced to 9/16 λ, an almost unidirectional type of pattern forms. A further slight reduction in the "short" side length to ½ λ produces a pattern that can be very useful in many circumstances. Two of the main lobes remain quite sharp and produce some gain while other main lobes have essentially disappeared from their usual location, thus leaving a deep null for about a 60 degrees arc in

one direction. Other responses produce a fairly full response broadside to the line of the antenna. Such an antenna pattern might be useful if one wanted to concentrate radiation in an easterly or westerly direction (producing a good null in the opposite direction) and still have a reasonable amount of north-south response. When the "short" side is reduced to either 7/16 or 3/8 λ, primarily broadside radiation takes place. Such a response would be ideal for the fellow who moans that he can't work anyone in a direction broadside to the line of direction of his long-wire antenna.

The patterns shown are only exactly true for a frequency or band where the antenna lengths are the electrical lengths shown. They do change with frequency. However, as a general approximation, they still will retain the same general shapes when, for instance, the 3λ antenna is operated on a frequency such that its electrical length is 1½λ. As the total electrical length of the antenna is made shorter, varying the feed point placement has less effect upon the horizontal pattern. It probably is not worthwhile to experiment with asymmetrical feed to vary the antenna pattern when the antenna electrical length is less than 1λ.

Feed Point Impedance

As the feed point is varied, the impedance presented will also vary. The range of variation depends upon such factors as the antenna element/wavelength diameter ratio and can go from 50 ohms to a few thousand ohms with thin-wire antennas.

One could simply feed the antenna with a resonant line such as 450 ohm open wire or twinlead and employ an antenna coupler at the transmitter end to derive a low impedance, non-reactive load for the transmitter. A transmatch coupler will easily handle the range of impedances encountered, for instance, and provides a handy means for multiband coupling to the antenna.

For those interested in single band operation and/or using a non-resonant feedline, the antenna impedance that must be matched can be calculated without too much complication. To a close degree, the feed point impedance of an asymmetrically fed antenna is one-half the combined impedance of two symmetrically fed antennas whose half length is equal, respectively, to the length of each side of the asymmetrical antenna. Some examples should make this calculation clear.

Suppose that an asymmetrically fed antenna is used having a "short" side of ¼λ and a "long" side of 3¼λ. The feed point impedance will be one-half the added feed point impedances of a symmetrical ½λ and 6½λ (13/2λ) antenna. The center impedance of a ½λ antenna is about 70 ohms and that of an odd multiple ½λ is the same, or also 70 ohms for the 13/2λ antenna. The combined impedance is 140 ohms, half of which is simply 70 ohms—the same as for an ordinary ½λ dipole. In this special case, an ordinary 50 or 70 ohm coaxial line can be used to feed the antenna directly, with the addition of a 1:1 balun, if desired, to preserve the feed-point balance.

As another example, slightly more complex, consider the situation if an asymmetrical antenna were used having a "short" side of 3/8λ and a "long" side of 3 1/8λ. To find the feed-point impedance, it is first necessary to determine the feed-point impedance of a symmetrical 3/4λ and 6¼λ antenna. These can be determined from the graphs shown in Fig. 3. The curve is used which corresponds to the wire diameter/wavelength ratio of the actual asymmetrical antenna. In this case, a λ/1000 ratio is assumed, which is slightly large for a wire antenna operated on ten meters, for instance, but close enough to produce meaningful results. Then, the center impedance of the 3/4λ symmetrical antenna is found to be about 500 ohms resistive and +500 ohms reactive (500 + j500). The center impedance of the symmetrical 6¼λ antenna cannot be read directly, but since the impedance values repeat every wavelength, the impedance value of the 6¼λ antenna is approximately the same as a 1¼ or 2 ¼λ antenna. From the graphs, the impedance value is 150 ohms resistive and -500 ohms reactive. The center impedance of the asymmetrical antenna is: $Z=½(500+j500+150-j500)=½(650)=325$ ohms.

In this case, the reactive portions of the two symmetrical antennas are equal in magnitude but opposite in sign, so they simply cancel. The resultant resistive 325 ohm feed-point impedance would offer a good match to a 300 ohm twinlead feedline, or the antenna could be fed via a 4:1 balun with 75 ohm line, thus taking care of the impedance matching problem and preserving the feed-point balance simultaneously.

The choice of other "short" and "long" lengths for the asymmetrical antenna may not, of course, offer such simple feed-point impedances. In such a case, one can either build a matching network to allow coupling to the antenna by a non-resonant feedline or accept some slight change in the radiation

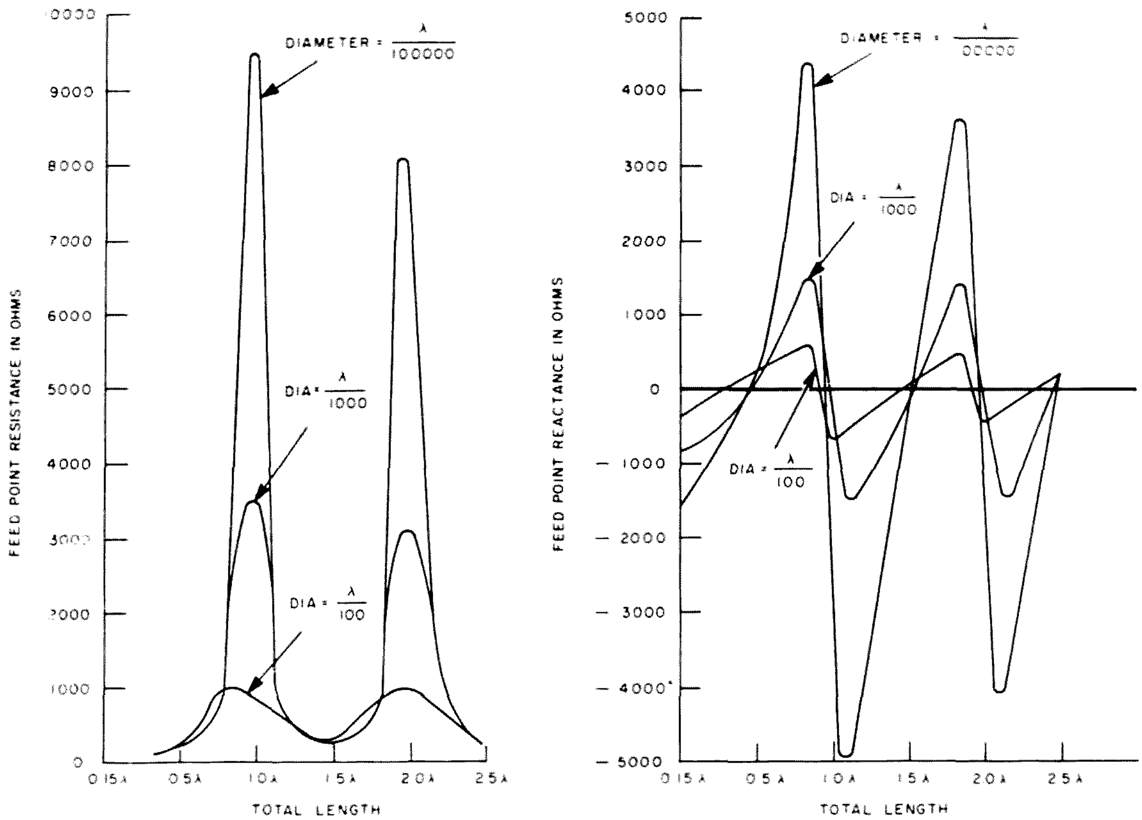

Fig. 3. Graphs of the feed-point resistive and reactive components of a symmetrical, center feed antenna. As explained in the text, these graphs can be used to calculate the feed-point impedance of an asymmetrical antenna.

pattern and use the closest "short" and "long" lengths which provide a convenient feed-point impedance.

Summary

So many factors affect antenna directivity, both in the horizontal and vertical planes, in a given actual installation, that only using the antenna can disclose its true performance. If, however, a long-wire antenna does exhibit dead spots in a particular direction or if it is desired to reduce the level of interference from a certain direction, asymmetrical feeding of the antenna offers a possible solution with extremely little effort and cost.

For those who would like to experiment and know something of transmission line stub switching, it is possible to develop, using the principles presented, a dual feedline antenna with a selectable pattern. When not used as the power transmission line to the antenna, the alternate feedline would be shorted to reflect a direct continuity of the antenna flat-top. To accomplish this, of course, the feederline length would be a multiple of ½λ.

With some imagination, the long-wire antenna can be turned into a versatile radiator. The operator who has room enough to erect one or, indeed, can only erect such a radiator should not discount its possibilities too quickly.

...W2EEY/1

Growing Beams In The Basement

It is a sad fact that most antenna "theory" is really empirical observation. Any ham who has tried to concoct his own antennas can vouch for the fact that no matter how good a design works on paper, the tinsnip and hacksaw test is the only one that really counts. So why not build them all? Before you start buying stock in an aluminum parts factory, consider this idea to minimize your cost and maximize your gain.

For years the aviation industry has used model planes to guess what might get off the ground and not fall apart. Similarly, model antennas can be used to find out cheaply which designs are likely to give good results and which should be slated for the trash. First select the highest frequency for which you can build a small oscillator. You don't need to get too wild, something between 500 and 1000 mc will give you a halfwave length that will be workably small. To keep peace with the local populace it would be a good idea to find one that doesn't interfere with TV.

The transmitter is a simple oscillator of whatever type is easiest to build. It is coupled to a simple halfwave folded dipole by a piece of 300 ohm TV ribbon. For greater effective power a shaped screen or dish can be placed behind it. The receiver is just a diode, a capacitor, a sensitive microammeter, and a variable resistor. At K9BDO we used a lab interferometer and obtained several promising designs for driven arrays.

Generally, this test system works well for determining the radiation patterns, front-to-back ratio, and gain of antenna designs. It can be used to find both the vertical and horizontal patterns, which is hard to do on full size antennas. It would be a good idea to make a dipole and a three element beam to serve as standards of measure. One thing that cannot be measured accurately is impedance, due to the effects of random capacitance and inductance. A lower frequency, such as six meters, must be used to make these measurements.

Materials for your donation to the world of invention can be almost anything, but I recommend aluminum clothesline and some pieces of soft wood. With this equipment almost anyone can embark on a career as an amateur antenna designer; and if you fail at that, you can always try writing articles.

David B. Cameron, WA4VQR

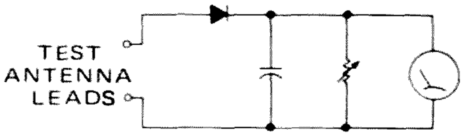

Fig. 1. The test system consists of a simple receiver with a diode, a capacitor, a microammeter, and a variable resistor.

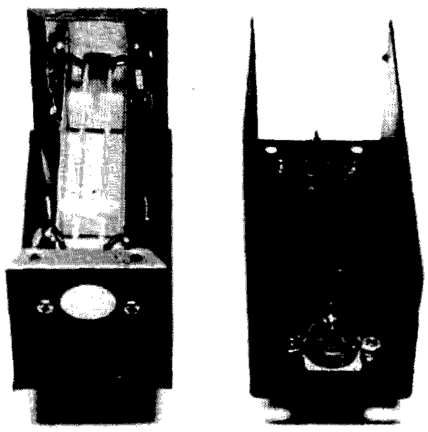
Rear Connectors for That Imported SWR Bridge

One of the best all-around values on today's ham market is the $10 imported SWR bridge. But a shortcoming of these units is that the connectors are obtrusively placed on the ends of the unit rather than on the rear. In use the unit is not nearly as compact as it looks. Fortunately, it is a simple matter to move the connectors to the rear.

Begin the modification by removing the back. Note the pieces of insulating plastic and cut vertical slits as indicated in the photograph. Unsolder the middle rod at each end and lift it straight out. Carefully remove the PL-259 connectors. Now cut two pieces of scrap aluminum 1"x1½". Drill the appropriate holes and mount the pieces to take the place of the two removed connectors.



The modified SWR Bridge with connectors on the rear.

Mount the PL-259s on the rear cover, centering them 11/16" from the end. Place the center rod atop the terminals and solder. The center rod should now occupy the same position as before, but soldered to terminals on the rear. Replace the cover, and the modification is complete.

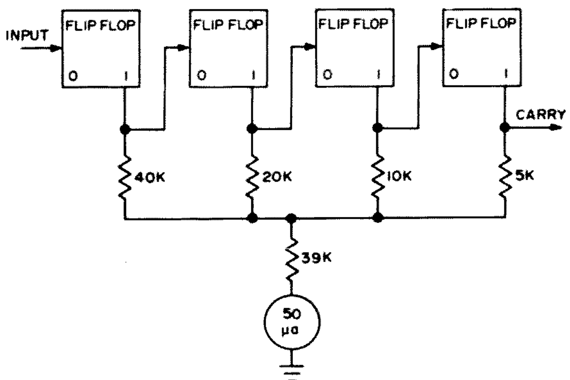
While accuracy on 6 and 2 meters and sensitivity in general may suffer slightly with the rear connector arrangement, few would deny the obvious advantages of the modification.

James C. Miller, III, WA4IQD

Add This Simple Decimal Readout to Your IC Counter

An integrated circuit counter is a pretty satisfying project and I can find no primrose paths in Wes Votipka's article in November '68 "73" magazine. One somewhat "un-American" (whatever *that* means) aspect of the counter described is that binary readout – you must sum the values of the lights on in each decade to translate. There is a fine excuse for this approach if illuminated readouts are required – in each decade four lamps and drivers do the job of ten lamps (nine, if zero is understood), drivers and a binary to decimal translator. If a diode matrix is used to translate, forty *good*, high back-resistance diodes are needed for each decade!

Now, my counter is not finished but perhaps my readout system will be of interest to others still in the building stage. This low cost approach gives a true decimal readout. I use a separate meter to indicate the output of each decade – 50 microampere meters function very well when connected directly to the outputs of 923 type flip flops. The trick is to properly weight the current passed to the meter by each flip flop of the decade. The circuit I've used is shown in the figure.



Note the binary relationships among the resistors – the least significant binary digit can only introduce one half the current supplied by the next more significant digit and so on. Logic levels of individual flip flops will be different, so equal increments of meter deflection will probably not be observed. However, the meter will assume very distinct positions for each count stored in the decade. Purists can trim resistance values to equalize deflection increments – I'm satisfied to let the chips fall where they will and mark the meter scales accordingly.

If there are some misgivings about cost – 50 microampere meters are seldom the cheapest on the list – imports go for about $3. Being pure Scotch I managed to cut that by picking up a batch of brand new photographic light meters from Olson Electronics in Akron, Ohio, at two for a dollar! These are 54 microampere movements and, though not cased, are beautifully made. I haven't tackled the mounting problem but it doesn't appear too difficult. Earl Bryant WA7EYR

San Francisco, Here I Come!

In connection with the hearing on the Miller suit, I will be in San Francisco from May 26th through the 30th. If any clubs in the area are interested in having a guest speaker with a lot to say, please drop a note to me at 73 telling me which night you like. Questions answered on anything and everything, if you really want to know what's going on.

Wayne, W2NSD/1

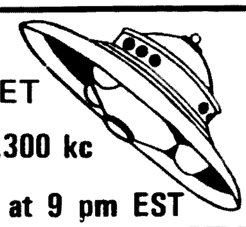
For Your Next Converter

Good old Sears & Roebuck has done it again. How many times have you battled with copper flashing material–trying to get it to take solder, attempting to form it into some reasonable facsimile of a box or VHF cavity? If you're tired of burned fingers and torch-soldering, take heart. Rush down to your nearest Sears & Roebuck store and invest about $2.50 in a roll of their Zinc-Copper alloy flashing. It comes 1 foot wide, and the rolls are 10 feet long. That's a lot of converters!

It takes solder beautifully. You can lay a bead with only a gun–no more torches. It forms easily, and cuts with standard scissors, or with a paper-cutter. In VHF and UHF applications, it performs at least as well as copper flashing–and it silver plates easily, to boot.

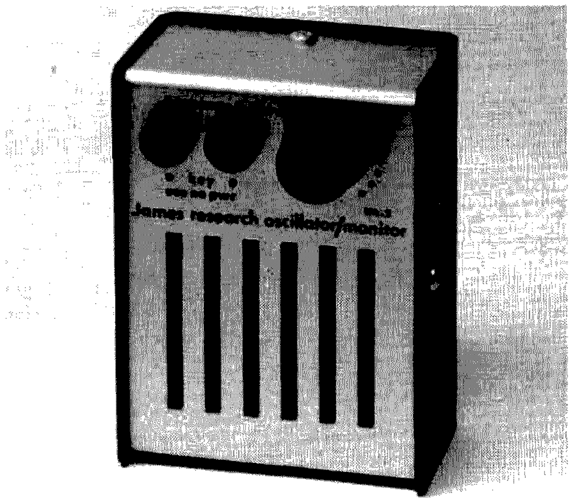
Thanks to Jay, K8CJY, for tipping me off to this great stuff!

Bob Grenell, W8RHR



73 Tests

The James Research Oscillator/Monitor, Mark 2 and Permaflex Key



Oscillator/Monitor is a very modest description of this extremely versatile piece of equipment. Housed in an anodized aluminum case about the size of a pack of cigarettes, this little unit does just about everything except stand up and sing "The Star Spangled Banner."

The Mark 2 will serve as a CW monitor, a code practice oscillator, an *rf* detector, an *rf* test device, and a test instrument to check diodes and semi-conductor devices of all types.

CW monitoring

The Mark 2 provides a reliable CW sidetone from any amateur transmitter regardless of power or frequency. It requires no connection to either the transmitter or key. An 8" stiff wire antenna picks up stray *rf* and triggers the monitor. A strong magnet is attached to the back of the case to allow it to be placed on the transmitter in the spot where the *rf* pickup will be best.

Code practice

The monitor can be connected to any keying device to produce a loud, click free audio tone. A tone control knob allows for adjustment to a comfortable listening tone.

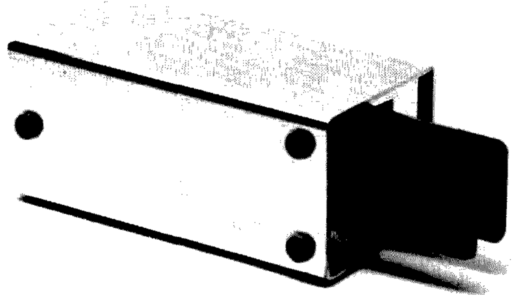
RF detection and testing

The high sensitivity and broadband characteristics of the monitor make it a valuable *rf* test instrument. It will detect the presence of *rf* by producing an audible tone and indicates relative power of the *rf* source by changing tone. No direct connection is required for *rf* in excess of 10 milliwatts. The monitor may be used as an effective tuning aid for transmitters or power oscillators. As the *rf* power increases, the tone becomes lower in pitch.

Component continuity and semi-conductor testing

For the testing of circuit or component continuity, the monitor has many advantages. Tests with the monitor are completely nondestructive since the power required can never exceed .0025 microwatts and the open circuit voltage is not over 1.5 volts. The maximum current that can pass through any component will not exceed 50 microamps. The monitor will test component resistances from zero to 100,000 ohms. Various resistance values will cause the tone of the monitor to change. It is possible to test for open or shorted conditions as well as partial continuity. Since the monitor is a polarized device, it will test such polarity sensitive components as semi-conductors and meters.

Available by direct mail only at the Miniprice of $14.95.



Permaflex key

The James Permaflex key is a manually operated single pole double throw switch

mechanism. It has two independent insulated contact paddles mounted to a contacting center support arm. The key is operated by light finger pressure against either of the two paddles. The key can be used with any electronic keyer or may be connected directly to a transmitter. The contacts are rated 8 amps at 28V dc which is far in excess of most transmitter requirements and are the heart of the key design since they eliminate the usual corrosion and cleaning problem associated with traditional silver contacts.

The silver contacts have a gold diffused coating.

The key is housed in a polished chrome-plated steel cabinet 1 9/16" square by 3 3/4" long and total weight is 10 oz. There are two independent sets of rubber feet. When one set is used, the key operates as a side-swiper type of key. When turned to the other set of feet, it can be used as a straight hand key. Selling for $19.95, it is hard to find a more versatile key.

All James Research products are designed and manufactured in the USA and are available by direct mail order only. They carry a one-year guarantee. James Research Co., Dept. AR-M, 11 Schermerhorn Street, Brooklyn, N.Y. 11201.

A "Compressed" Vertical for 160

This antenna requires only half the height of a true quarter wave vertical.

F. J. Bauer, Jr., W6FPO
P. O. Box 870
Felton, California 95018

It is not the purpose of this article to go into the relative merits of horizontal and vertical antennas for 160, but rather to present an interesting and practical design for those amateurs who would like to try a vertical without going to excessive heights or resorting to critical loading gimmicks. As is well known, a true quarter wave vertical for this band would require a height of at least 120 feet or so, which is usually out of the question for most amateurs. The antenna described here requires only half this height and as far as I can tell by experiment, the radiation efficiency is about as good as that of the full length antenna.

The basic design of the antenna is shown in Fig. 1. About the same conductor length is used as would be needed for a full length vertical. Also most of the horizontal radiation is cancelled by the adjacent horizontal sections of the radiator as shown in the figure. Complete cancellation will, of course, not be obtained since the antenna currents in the adjacent horizontal sections are not quite equal and opposite. However, on-the-air tests at night have consistently shown less QSB than that obtained from horizontal antennas, which seems to indicate that the antenna does behave like a true vertical.

The antenna is built most simply by stapling insulated wire to a wooden mast. Do not use a metal tower or mast. The antenna support I used is shown in Fig. 2. The mast is pivoted at the roof level with the lower third extending towards the ground as shown. Six bricks in a pail are used as a temporary counterweight whenever it is necessary to raise or lower the antenna. Two guy wires as shown were found adequate since no high winds are experienced at this QTH.

The first experimental antenna built used no. 12 weatherproof outdoor wire arranged

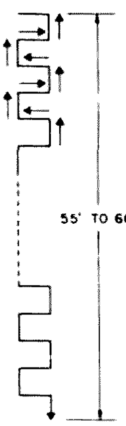


Fig. 1. Basic antenna wire layout. (Arrows indicate instantaneous current flow and cancellation of horizontal radiation.

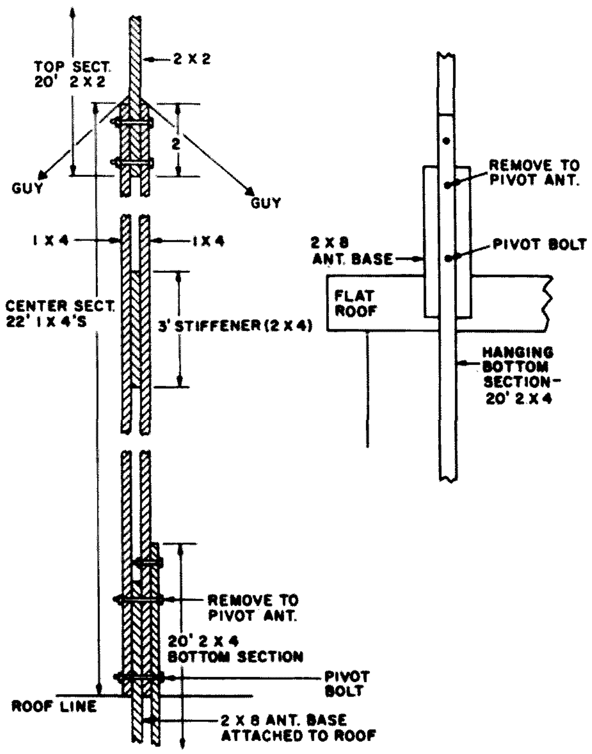

Fig. 2. Antenna support.

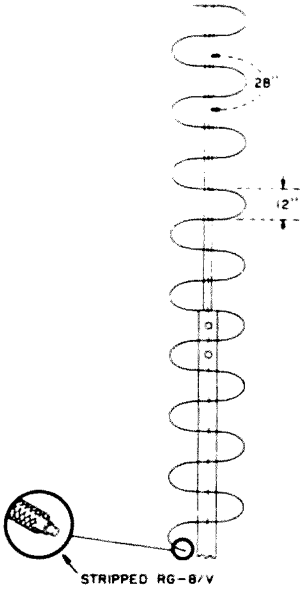

Fig. 3. Antenna configuration using stripped RG-8/U.

in 6-inch squares as shown in Fig. 1. It was about 32 feet high and proved quite effective on 75 when worked against ground as a quarter wave vertical. The second and final antenna was made from old RG8/U coaxial cable with the outer braid removed. Since the stripped RG-8/U did not lend itself to a square configuration, the antenna was made in a series of loops as shown in Fig. 3. With the dimensions shown, the antenna resonated at 2150 kHz against ground.

This was a little high for the frequency of interest (1990 kHz) and would have required making the antenna about four feet longer. Since I was out of lumber as well as energy, I decided to use a simple series tuned antenna coupler as shown in Fig. 4. The coupler was also satisfactory for tuning to the 1900-1925 kHz segment of the band. The simplest way to adjust the antenna system is to "grid dip" the tuner to the operating frequency and then use the transmitter pi network to load the transmitter in the normal manner.

I had no luck loading the transmitter "pi" network directly into the antenna because the antenna impedance was too low for the "pi" network–about 30 ohms as measured on an antennascope. No attempt was made to feed the antenna with a transmission line, since the antenna base and ground were both located right outside the shack window.

This antenna, like all quarter wave antennas requires a good ground system. Radials, of

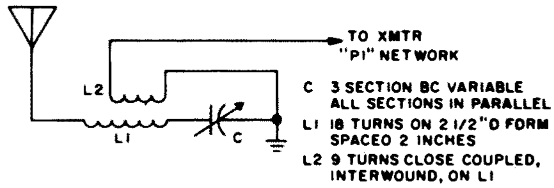

Fig. 4. Antenna Coupler.

course, would be best if you have the space and the energy to install them. I used three eight-foot ground rods in conjunction with three water pipe ground connections, all tied together. The antenna current was the same whether a half wave or quarter wave antenna was used, so I assumed that the ground system was fairly efficient.

As for results obtained with this antenna, I have had neither the desire nor the ambition to operate odd hours and check the antenna on some real DX. However, tests run with stations 250 miles or so out indicate a two S-unit gain at times over a low horizontal antenna. Strangely enough, stations closer in (40 miles or less) favor the horizontal

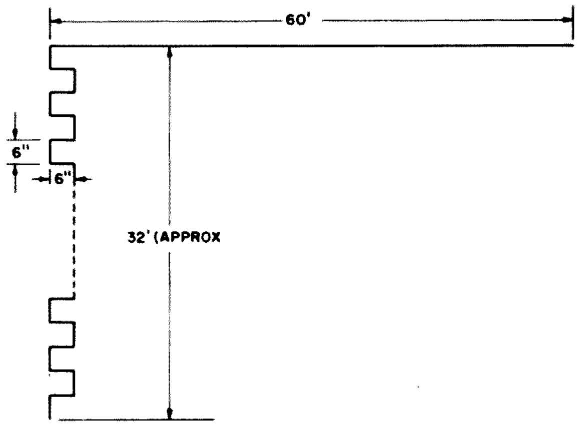

Fig. 5. Inverted "L" configuration.

antenna by two S-units or so. Excellent reports have also been received when working Idaho and Wyoming stations from this QTH with 50 watts input.

For those amateurs who think 60 feet or so is still too high for an antenna, I suggest an inverted "L" configuration as shown in Fig. 5. The antenna is, in effect, a 1/8 wave vertical with a 1/8 wave horizontal wire added. It has given a good account of itself as an all around 160 meter antenna both for DX and local work and is only 32 feet high.

No matter which antenna type you decide to build, you will be sure to have a conversation piece–on the roof, that is.

...W6FPO

Seven-Step Class A Transistor Amplifier Design

Edward A. Lawrence, WA5SWD/6
218 Haloid
Ridgecrest, California 93555

Designing a Class A transistor amplifier is not so hard if you are willing to make a few reasonable assumptions. As a matter of fact, it is just an exercise in Ohm's Law. The biggest assumption is that the transistor has a reasonably high gain, and a reasonably low leakage. This procedure works for NPN, PNP, Silicon and Germanium. You don't care if it is Ge or Si until the 4th step, and if it is NPN or PNP until the last.

If you need a particular gain (voltage gain), you can determine the proper values to get it, or if you want all the gain you can get, take the same procedure, but bypass the emitter resistor. Refer to **Fig. 1** for the seven steps and an example to show how they are used.

Once you have designed the amplifier and assembled it, check Vc. It should be about one-half the supply voltage. If it isn't, change RB2. Increase it if Vc is too low, or vice versa. If you build for a set gain, remember to allow for the loading of the next stage by figuring the load in parallel with RL in step 2. If you decided to go all out for gain, pick CE to have a reactance of about one-tenth the value of RE at the lowest frequency you plan to pass through the amplifier.

This procedure will allow you to design a workable amplifier for almost all applications for Class A RC coupled amplifiers. You may come upon a special case, but I have developed this procedure while working in various Engineering Departments during the last three years, so I sincerely doubt it.

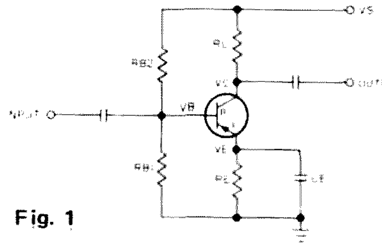

Fig. 1

1. Pick RL (.6-20K) IC=.5VS/RL
2. Calculate RE (Gain 1-25) RE=RL/Gain
3. Calculate VE (IE about equal to IC) VE=IC(RE)
4. Add VBE to VE to get VB. VBE=.3v for Ge, .6 for Si VB=VE + VBE
5. Pick RB1 (3.3-27K)
6. Calculate RB2 RB2=RB1(VS-VB/VB)
7. If NPN, VS is Positive If PNP, VS is Negative

Example: NPN Si, 12VDC, Gain of 10

1. RL=10K, IC=6/10K=.6 ma
2. RE=10K/10=1K
3. VE=$.6\times10^{-3}\times1\times10^{3}$=.6VDC
4. VB=.6+.6=1.2VDC
5. RB1=12K
6. RB2 in K ohms RB2=12(12-1.2/1.2)=12(9)=108, use 110 K
7. VS is Positive

Additional Remarks

Step 1: To be able to get the maximum voltage swing out before clipping, the collector needs to be set one-half the effective supply voltage below supply voltage. To find effective supply voltage, subtract VE from VS. Then drop half of that across RL.

Step 2: This step presumes that the gain of the transistor is higher than the gain the circuit asks for. Normally this will be the case. If you want all the gain you can get, bypass the emitter resistor. This will increase the distortion somewhat. Usually the distortion will still be low enough for amateur purposes, but not low enough for "Hi-Fi".

Step 3: Since the base current is small compared to the collector current, this is a good approximation. It is not advisable to ground the emitter directly, as this reduces the dc stability greatly. It also makes this procedure almost useless, since some of the assumptions no longer hold. And one resistor and a capacitor are a very small price to pay for the advantages gained. Also, as a rule, the more voltage you drop across the emitter resistor, the more stable the circuit will be with temperature changes.

Step 4: In actual practice, VBE will not be exactly .2 or .6 vdc, but these values will be very close. The emitter follows the base voltage, and not the reverse, as this procedure might seem to indicate. But this is the simpler way to design the amplifier.

Step 5: No correction has been made for base current, so VB may be slightly lower than this step indicates. The lower RB 1 and RB 2 are, the less base current will affect the result. But this also lowers the input impedance, which makes the amplifier harder to drive.

... WA5SWD/6

Even Better Gamma

In the Sept. '66 *73*, the improved gamma match can be further improved by using the printed circuit board in one piece as in Fig. 1. This makes for a neater job and less chance of wire breakage. K6ZHO's idea is a fine one.

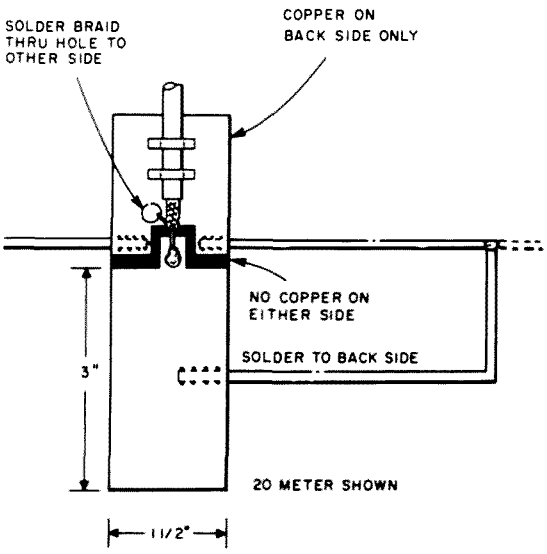

Fig. 1. Details of the improved gamma-match.

The boards should be of either epoxy or polyester. These will absorb less moisture and stand up better in the weather. Newark lists both of these items in their catalog. The epoxy 3x6 is $1.14, # 19F3213. The polyester 3x6 is $ .73, # 19F3228. Kepro is the vender.

Paul A. White, W6BKX

A Cheap and Dirty 15-Meter Antenna for the Longhaul DX

Paul Cook III, WA7CSK
2943 N.E. 178th Street
Seattle, Washington 98155

The $4.98 Novice Special

Parts List:
200 ft. of wire
2–2x4 boards, about 12 ft. long
25 ft. of RG59/U coaxial cable
50 ft. of RG58/U coaxial cable
Electrical tape
Solder
4–egg type insulators

There's no doubt about it, with the sunspot cycle where it is now, 15 meters is the best band for the Novice who wants to work the world. Openings to all continents occur daily, and flea powered Novice stations are picking off the rare DX like shooting fish in a barrel. The word seems to be getting out, and now more and more WN callsigns are heard on 15. When the choice DX moves in on frequency, there are even a few pileups – an occurence formerly reserved for 20 meters. If you want to work *ALL* of the DX with good consistency, you're going to have to have a good signal.

Most Novices today run 75 watts into a simple dipole antenna, but if you want to be "top dog" in the pileups, you'll just have to do one better than the next guy. One way of doing this is to increase your transmitter power beyond the Novice limit of 75 watts. However, that just means big trouble with the FCC, so a better thing to do is to put in a better antenna. In this article I'm going to show you how to build a beam antenna that will beef up your signal so that you can really "sock-it-to-'em" on 15.

The antenna that I am going to describe is called a phased vertical array. It consists basically to two 1/4 wave vertical antennas with 1/4 wave radials placed 3/8 wavelength apart. The antenna is fed with appropriate matching and phasing sections and has a gain of about 6 db. This 6 db of signal improvement is the same as if you changed your transmitter power from 75 watts to 300 watts! The antenna is very cheap and easy to build, and you might have all of the parts, so then it may cost you nothing.

Theory

Basically, the antenna consists of two vertical ground plane antennas placed in "phase" with each other. This means that the two ground planes are placed at a certain distance apart so that the signals from both antennas complement each other and produce higher radiation in one direction. This works the same for receiving. In this way we (1) reduce QRM to stations in other directions because they don't hear us, (2) reduce QRM from stations in other directions because we don't hear them, (3) increase our signal strength in the desired direction, and (4) increase the received signal strength from stations in the desired direction. This all adds up to higher station flexibility and efficiency.

Construction

To build the antenna you will need the materials that are listed in the parts list. The two boards can be mounted on the side of a roof, like my own installation, or mounted on the ground. Before you erect the boards, pound a nail in each end of both. Then measure out 11 feet of wire and connect it to two egg insulators. Do this for both boards, and be sure to solder. Next, take fishline, rope, or what have you, and string up the wires vertically on the boards, tying the insulators to the nails. Then erect the boards. When you do this, be sure that both boards are vertical and 16-1/2 feet apart.

Feedline and Matching Section

Now you have constructed the antenna, and it's time to piece together the matching section and feedline.

Take one 11 foot piece of RG59/U 75 ohm coax and splice it to an 11 foot piece of RG58/U 52 ohm coax, as shown in **Fig. 1a.** Do a neat, careful job and wrap the connection well with electrical tape. If you have some Krylon spray, use it on the connection to do a completely weatherproof job.

Get 11 feet of RG59/U and the RG58/U

Fig. 1A

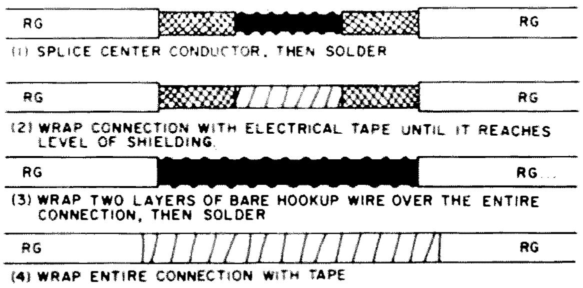

Fig. 1B

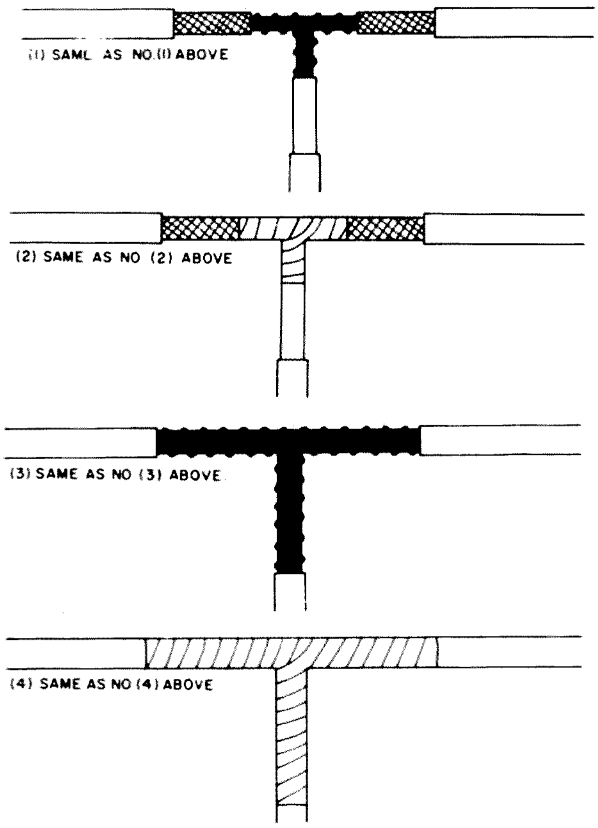

that goes to the shack (as shown in Fig. 2) and make the three way splice as shown in Fig. 1b. Here again, if you have Krylon, use it.

Now lay out the matching section on the ground or the roof. Don't coil up the coax or let any kinks get in it. Instead, lay it out so that it lies in a gentle curve with no sharp turns as shown in Fig. 2. Solder the center conductors from the two ends of the matching section to the antenna wires at the base of the boards as shown in Fig. 3. Then solder the outer conductor and eight or more 11 foot ground radials to the nail on each base. Run each radial out from the base fairly perpendicular to the vertical boards and lay

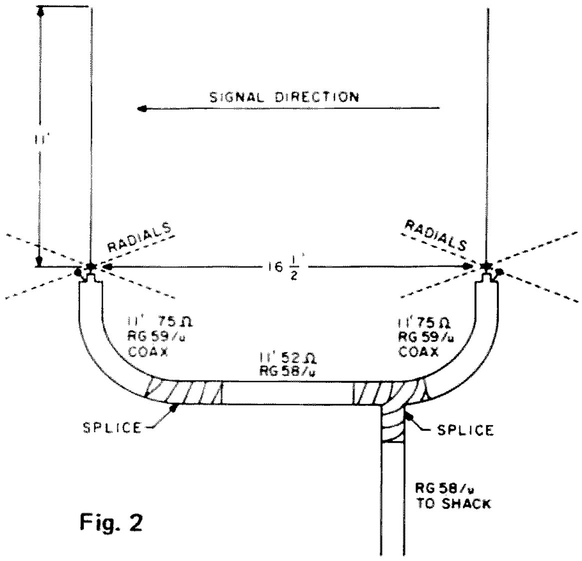

Fig. 2

them on the roof or ground in a fashion similar to the spokes of a wheel. The radials improve the low angle of radiation which brings in the long distance signals better.

Operation

Now that you have completed the antenna, try it out on the air! When I tried mine out with the antenna aimed toward Europe the first time on the air, I knocked off two SM's, a G3, and I1, and a DL with only 75 watts. This little antenna is a real bomb! If you wish to change the directivity of the antenna, then substitute PL-259

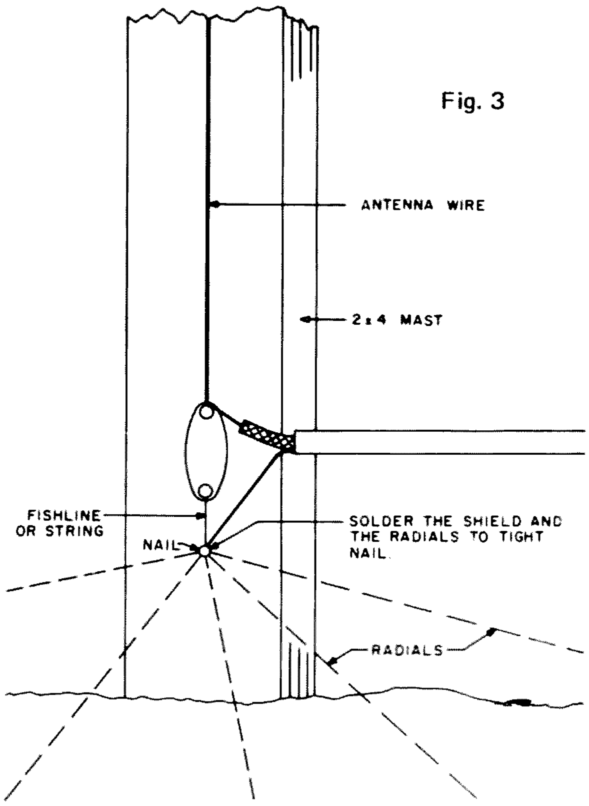

Fig. 3

coaxial plugs, a double female connector, and a Tee connector for the splices. If you connect these as shown in **Fig. 2**, you will have your signal aimed in the direction shown. But if you take the RG58/U matching section out, and connect it exactly the same way, only on the other side of the Tee connector, you will reverse the direction of your signal. If you leave out the RG58/U matching section altogether, you will end up with a figure eight type bidirectional pattern that is perpendicular to the two previous patterns.

In conclusion, if you try this antenna, I'm sure that you'll work a lot of DX. The antenna is efficient and works well, and will help you to get the edge on the other stations. If anyone has any problems with this antenna, please write to me and I'll be happy to advise. If you build this antenna, write to me anyway and tell me how it works!

. . . WA7CSK

FCC ACTS TO REVOKE AMATEUR LICENSES ON OBSCENITY CHARGES

The Federal Communications Communications Commission took action today to revoke the operator licenses of three Amateur Radio Service operators on charges of obscene, indecent or profane radio communications. The Commission ordered Steven P. Bowman, of Sikeston, Mo.; Kenneth C. Henry of Anderson, Inc., and Gary Overman, of New Castle, Ind., to show cause why their licenses should not be revoked. The three operator licenses were also ordered to be suspended.

In addition to the obscenity charges, other violations included transmission of false or deceptive signals or communications, failure to identify stations properly, transmission of unidentified communications or signals and willful or malicious interference to radio communications of other amateur stations.

The Commission said that the three amateur licensees had repeatedly and willfully violated the Rules. The enforcement actions followed investigations carried out by the FCC Field Engineering Bureau and the FBI after complaints were received from other amateur radio operators.

Actions by the Commission March 14, 1969, by its Chief, Safety and Special Radio Services Bureau. By Orders, and Orders to Show Cause.

How to Fly Your Kite

M. B. Crowley, EI4R
78 Church Street
Listowel, Co., Kerry
Ireland

(Or a vertical long wire on last year's EIØRF Expedition)

The location of the expedition "BEAR" island (rechristened "BEER" island) was good, but the shack QTH was surrounded on three sides by mountains. The problem was to put out sufficient wire for our 1.7 MHz bands; and 260 feet of wire can present quite a problem on such a location. A vertical aerial would be fine, but 260 feet of support pole was out of the question on an island expedition. Gas-filled balloons are not easily come by where we were located. The solution—yes—a kite.

Having in mind from my boyhood days the dimensions of a small kite without frills or tails that, once aloft, in a light breeze could be tied to a convenient peg and forgotten about, it seemed to me that this was the ideal solution.

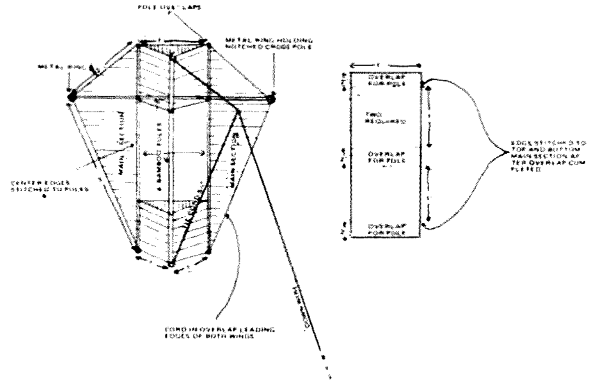
One of our boys gave me some 260 feet of braided copper wire from the old emergency TX "The Gibson Girl" used by aviators in the Second World War. This wire seemed ideal to fly the kite with and weighed only one pound.

Having some half-inch (average) diameter bamboo, garden variety poles on hand, and having persuaded the XYL to let me have some old bed sheets from her junk box, the next undertaking was to scale up the original version of the kiddie kite.

From the diagrams it can be seen that the dimensions and shape are straight forward and present no mathematical problems to scale up to the required size. In my case, this amounted to bamboo poles of 5 feet in length.

The materials required are four bamboo poles, one large section of sheeting and two smaller sections of sheeting. Three lengths of tough light cording are also required. The illustrations give the dimensions of these pieces. When cutting the cloth, do not forget to include that extra width of cloth on the leading edges of the wings, which, when folded back on itself and stitched, will hold the two pieces of cord that strengthen the wing edges.

It would at this stage be advisable to secure the services of the XYL or YL to machine stitch the edging. Go careful here, for this sort of favor could cost you later; why else



do I write this article for 73 Magazine?

The center pieces are stitched with a larger overlap to hold the bamboo poles, which should slip into place with a reasonably tight fit, the ends being then stitched over by hand needle to hold the poles permanently in place.

The overall weight of the kite and poles was 3 pounds. The down wire should be tied approximately a quarter way down the tie cord. Unwind about 50 feet of the downwire and have a helper push the kite up into the wind with the downwire held tight. In a modest steady breeze the kite will lift gently and the remainder of the wire can be paid out. If the kite pulls too hard and slips sideways, tie the downlead further up the tie cord until balance is achieved and the downwire is near vertical. In a light breeze and from the pull on the downwire, it seems to me that this size kite could support about 3 pounds of downwire.

One word of warning. If the breeze is strong, do not allow the junior operator to play around with this size kite. There are easier ways of flying nowadays. Once the kite is aloft, with the required length of wire, tie the downlead to a convenient tie point, through an insulator. A lead to the shack from the tie point will give you a vertical antenna without match, provided the wind remains. Force 9 winds should be avoided as your favorite rig may disappear out the shack window. Happy flying hours, fair winds and tight wires.

In Search of a Better Angle

Observations and Suggestions Involving HF Radiation Angle Manipulation

When HF DX-getting tactics are discussed, sooner or later the subject will center around antennas, for the antenna, coupled with its geographic positioning, will ultimately make or break a DXer. A status is eventually achieved, however, when the serious DXer has put up the largest and tallest antenna he cared or dared to, or a point of "signal strength stagnation" is reached. For most of us this is a frustrating level, for it probably still means an S-unit or three gap between us and the big guns. Even if you feel you're near the top, however, there were undoubtedly times when these extra db would have come in handy. This article is no magic panacea for combatting a W3CRA or W5VA in the pileups, but knowing a little about radiation angle manipulation may give you something to think about along those lines.

Low angle advantages

I think many of us have operated enough to realize the importance placed upon an antenna with a very long boom perched upon a very high tower. The fellows with the biggest combinations of these two, possibly coupled with an elegant location, constitute the big guns, or the big DXers and contest winners.

A major reason for their seeming invulnerability is the very low vertical radiation angles associated with such an antenna combination. For normal F2 propagation paths, the best situation is for your signal to reach a distant point in the least number of "hops" or reflections. Up to about 2500 miles or so, one hop propagation is possible, but after that, an earth reflection is necessary. Now the signal is being decreased by a number of losses; most pertinent here are distance losses due to spacial spreading, and ground losses at each earthly hop. Distance loss is of course a function of distance; a lower reflection angle means less distance travelled and therefore less loss than a higher angle, although the difference may only amount to a db or two. Much more important are the ground losses. While sea reflections are less critical of incident angle, ground reflections may result in four or five db differences per hop between low and high angles, depending upon frequency (1). Here is one place where the big guns clean up! One or two less of these lossy earth hops experienced by signals approaching from a high angle and we're talking about S-units of difference. Fortunately, all is not this rosy for the people with the low take-off angles.

NBS observations – good news?

The good news is that in most cases, these things I just talked about occur only for "storybook" propagation under ideal conditions. What about the real world? W. F. Utlaut presented an interesting report along those lines in our National Bureau of Standards research journal *Radio Propagation* where he made a detailed study of radiation angle importance. The results were slightly astounding (2).

Using a VOA transmitter in Munich, Germany, and receiving antennas in Boulder, Colorado (a receiver was also located in Slough, England, but results were consistent with those in Boulder), all with carefully calculated radiation patterns, Utlaut attempted to find out if low angles were that

Boulder Antenna	Height ft	Radiation Angle deg
1B	50	15.6
2B	135	5.2
3B	310	2.3
4B	485	1.4
5B	985	0.7

Table 1

good. From March to June, 1959, on 20 MHz, the Munich station transmitted while the receivers in Boulder carefully recorded daily signal variations. Five receiving antennas were used, varying in vertical radiation angle from .7 to 15.6 degrees. Table 1 lists the various antennas, heights, and associated radiation angles, while Figs. **1A**, **1B**, **1C**, and **1D** are graphs of hourly median signal strength for the Munich to Boulder path from March to June. Transmitting antennas at the Munich end were rhombics and vertical main lobes between 12 and 16 degrees (two antennas used).

While receiving data extended through times when the predicted MUF (Maximum Usable Frequencies) were below the operating frequencies, this may be slightly impractical from the amateur standpoint where relatively low power is usually employed. Close inspection of Figs. **1A-D** will bring out a number of interesting points:

1. No one radiation angle dominated for an entire average day during the time the band was open. (MUF greater than 20 MHz.)
2. Low angles seemed more of an asset during a summer month (June) than during a spring month (March). In addition, the spread of signal strength between one angle and another was greater during the summer months than during the spring.
3. Lower angles were characteristically "band openers" with dominance here noted in excess of three S-units over the highest angle.
4. Higher angles seemed valuable during the midday hours, with some advantages over the lowest angle in excess of two S-units at these times. (Remember, these were monthly averages; there were undoubtedly times when these differences were greater.)

The basic observation by Utlaut in this report was that statistically, and over an average 24-hour period, best results could be gained by using the lowest radiation angle possible. This involved times when the predicted MUF was much below 20 MHz; which

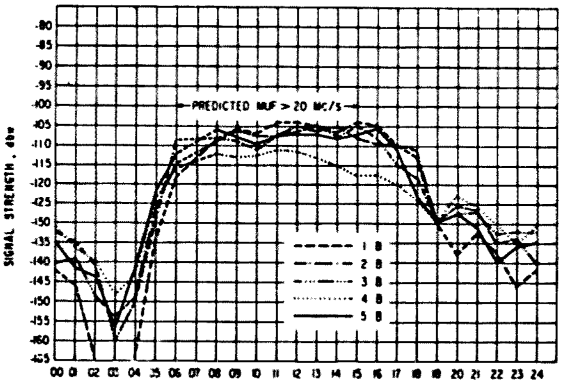

Fig. 1A. Hourly median signal strength for Munich to Boulder path, March, 1959.

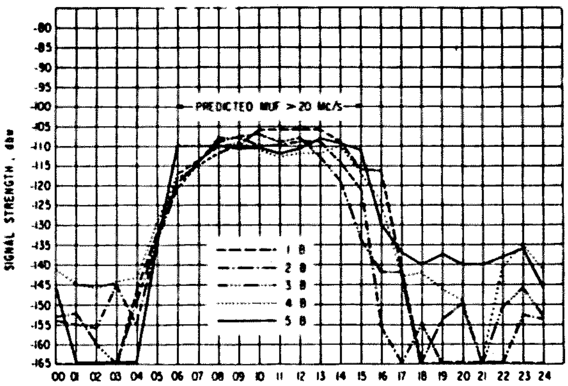

Fig. 1B. Hourly median signal strength for Munich to Boulder path, April 1959.

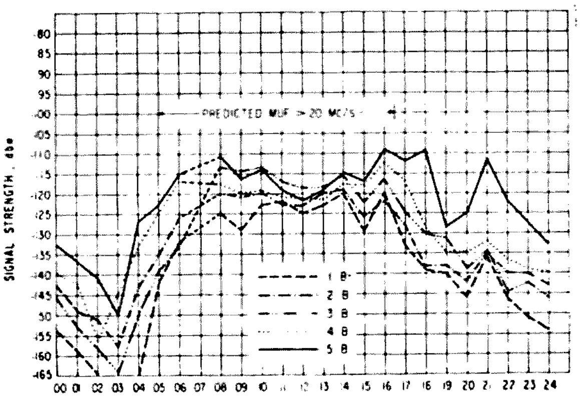

Fig. 1C. Hourly median signal strength for Munich to Boulder path, May 1959.

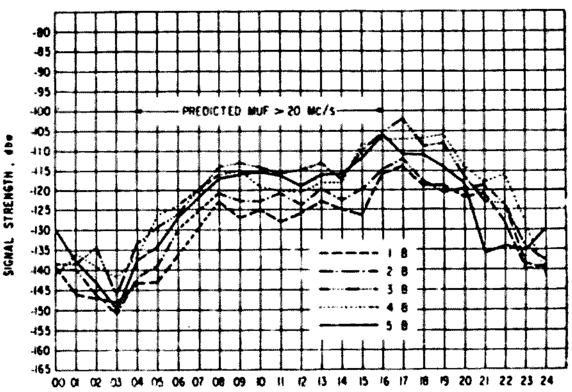

Fig. 1D. Hourly median signal strength for Munich to Boulder path, June, 1959. Transmitter in all cases was off the air from 0600 to 0800 MST. (1)

would probably mean communication below amateur capabilities. Looking at times when the MUF was 20 MHz or above, or when the band was open for possible amateur contacts, seems a slightly different story, with the "best" angle rapidly changing with time. The two most practical antennas, with realistically achievable angles, were 1B and 2B, representing the small time DXer (height 50 feet, angle 15.6 degrees) and the big gun (height 135 feet, angle 5.2 degrees) respectively. Although most differences between these two antennas were in the range of 5 db, special note should be taken of the April graph at about 1600 MST when antenna 1B (small time DXer) had the astronomical edge of 40 db over antenna 2B (the big gun)!

Possible explanations – ray paths and angles

Reasons for such phenomona are varied but usually of a complicated nature; the important point is that they do exist. A possible "easy" answer seems to lie in another recent finding by our Bureau of Standards; while a low radiation angle nets great skip distances, in most cases the absolute longest skip is achieved by a very high angled ray. Fig. 2 illustrates. Ray paths 1, 2, and 3 follow the generally accepted propagation theories – the lower the take-off angle, the greater the distance. Ray 5, however, the highest angled ray before ionospheric penetration takes place, actually out-distances the lowest angled ray! This is apparently the case for most propagation paths, as shown in another NBS graph, Fig. 3. This shows in a general case, that for any skip distance D, two ray paths are possible at any frequency below the exact MUF – either a high or low angled ray. Note, however, that the high angled ray is critically dependent upon the correct angle. Note also, in Fig. 2 again, that the high angle signal is spending much more time in the lossy ionosphere than the lower angles.

Fig. 4 depicts even a more frightening possibility. This is a government ionogram, or graphical picture showing path time ver-

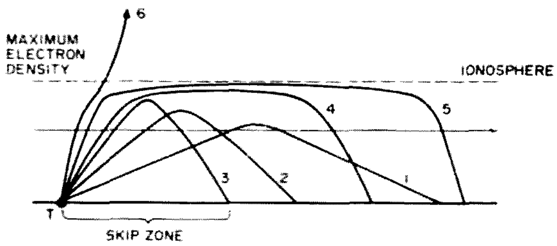

Fig. 2. Possible ray paths at a fixed frequency with varying vertical radiation angle. Note that the highest angled ray, #5, outdistances even the lowest angled ray, #3. (2)

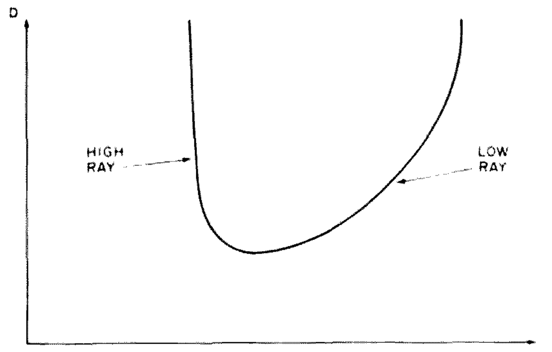

Fig. 3. Variation in skip distance D with vertical radiation angle Ø. Note how critically dependent the skip distance is upon small changes in angle for the high ray. (2)

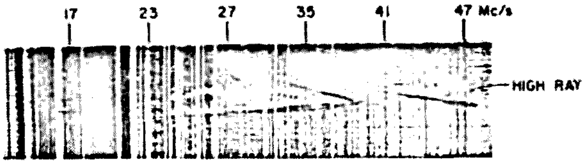

Fig. 4. Ottawa, Slough ionogram for November 14, 1957 at 1556 UT. Note that above 39 MHz only reflection of the high angle ray occurs. (2) (By permission of the Chief Superintendent DRTE.)

sus frequency, for, in this case, an Ottawa to Slough, England path. The horizontal lines show the high and low rays as reflected by a pulsed signal. The "omigosh" data here is that above 39 MHz, reflection occurred *only* with the high angle ray; low angle reflection was simply nonexistant!

A few more easily talked about reasons for the "best" angle to vary involve the great number of possible paths that a ray may "use" when skip distances are great. Fig. 5 illustrates two cases that could prevail along a DX path, although any combination of these hops are possible. Sporadic E clouds enjoy floating around, particularly during the summer months, and may enhance or belittle a band opening if one is hit. Since they are relatively small, a difference in take-off angle may result in a miss by one station, a hit by another, constituting different paths travelled, and ultimately differing signal strengths at the DX end. A similar situation may exist for the more stable E and F1 layers as well. Also, as suggested in Fig. 3, the number of possible paths decreases as the operating frequency approaches the MUF. The NBS tests were started in the spring, with the daytime MUF much above the operating frequency at that phase of the sunspot cycle, so many combinations of paths were possible. Many were apparently high angled paths. As summer approached, the daytime MUF was nearer 20

MHz, and consequently less paths available; the last path to go (at the exact MUF) apparently is characteristically low angled, hence the better results with low angles in the summer. Finally, the ionosphere is full of simple flaws, such as "thin" and "thick" spots, holes, and tilts, all of which play important roles in determining which path a signal may take, and all of which in some way are connected with the incident signal's vertical takeoff angle. What I'm trying to say is that there apparently is no year-round "best" angle, and for consistent results, it would be nice to be able to change the antenna's radiation angle quickly and accurately.

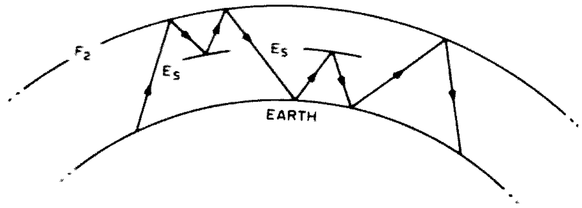

Fig. 5. Possible ray paths for typical F_2 propagation. Any combination of these F and E-layer bounces may occur.

Three methods and results

Accomplishing this accurate radiation angle change is not as hard or expensive as might be guessed; many DXers have undoubtedly tried the suggestions I'm about to present and have, hopefully, met with some degree of success. I'll concern myself with horizontally polarized antennas only, since they are not as greatly subject to ground losses that vary from place to place, and since they are more highly regarded in DX circles.

The vertical radiation pattern of anyone's antenna is, of course, a point by point multiplication of antenna's free space pattern and the ground reflection pattern. The free space pattern is dependent upon the antenna's ability to focus the signal; the lobes or plots of transmitted intensity from such an antenna will lie at an angle of zero degrees with the horizontal. Ground reflection patterns of any horizontal antenna are basically a function of antenna height above a perfect ground. These two patterns, plus a small compensation factor for those of us without a perfect ground, as well as considerations for trees, buildings, wires, or other obstructions, make up the real radiation pattern. Fig. 6 shows a simple example of this three step process.

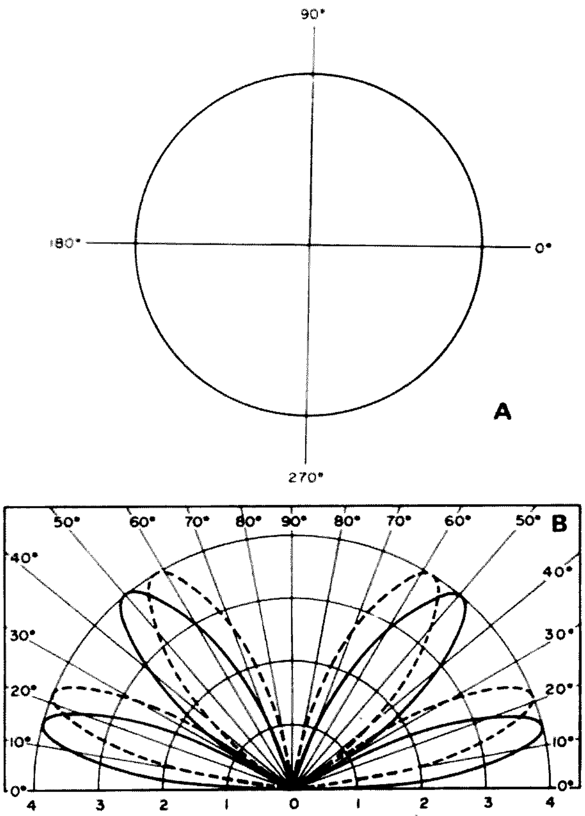

Fig. 6. Example of real radiation pattern determination. Fig. 6A is the vertical pattern of a half-wave dipole in free space for a plane perpendicular to the wire axis. Fig. 6B is the vertical ground reflection pattern in all directions for such an antenna at a height λ above a perfect ground. At the same time, 6B is the ideal resultant when A and the ground reflection pattern are multiplied together point by point for a plane perpendicular to the wire. The dotted line represents a possible final result taking into account obstructions and a less than perfect ground. (3)

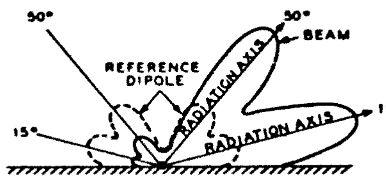

Fig. 7. Overlayed patterns of a reference dipole and a three element parasitic array, both at a height of one wavelength. Vertical lobes of both remain at same angle of elevation and depend only upon height above ground. (4)

The Armstrong method

Antennas with parasitic elements are little different in these respects, as shown in **Fig. 7**. Probably the simplest method of radiation manipulation, then, would involve changing the multiplicative ground reflection pattern. Since for horizontally polarized antennas, the ground reflection pattern is a function only of height above ground, this is easily accomplished by varying the antenna's height. **Fig. 8** shows graphically this relationship for antennas over flat terrain. Note how

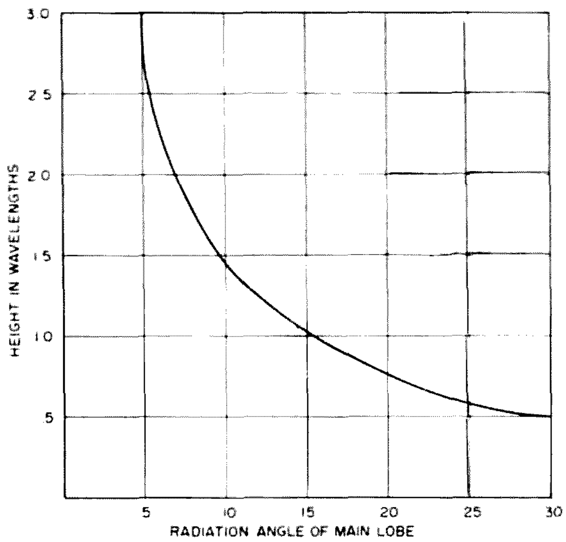

Fig. 8. Relationship between main radiation lobe elevation and height above ground for horizontal antennas above flat terrain. Note how difficult takeoff angles of less than 5 degrees are to achieve in such a situation.

difficult it is to achieve take-off angles of less than 5°. Fortunately, the severe requirements of this graph can be lessened if the antenna foreground is sloping. The math becomes a little embarrassing, but your actual radiation angle can be calculated in such a situation. A more complete analysis is given in "Radio Transmission in the Lower Atmosphere" by Bailey, Bateman, and Kirby, *PIRE*, October, 1955.

Lowering or raising the antenna is then a distinct possibility and although frequently practiced, it's usually agonizingly slow, and hard on arms and winches. It can be helpful, however, for short operating periods, such as contests or DXpedition chasing, when the lowering or raising need only be done once or twice per day.

Stacking

A much better method involves vertical stacking. While not going into the rigors of stacking dimensions, (A very good analysis can be found in "Optimum Stacking Spacings in Antenna Arrays" by H. W. Kasper, K2GAL, *QST*, April, 1958.) I will say that for best results, the antennas should be stacked for maximum gain, with the bottom bay at least $\lambda/2$ off the ground, more if there are numerous obstructions. For three element yagis, this involves spacing of at least 3/4 λ, a troublesome distance for 14 MHz, but a distinct possibility on 21 and 28 MHz. Aside from the three db maximum attainable gain if done correctly, this stacking sharpens the vertical lobes, although the antenna's actual height is now at the midpoint between antennas.

Interesting results can be achieved if an antenna switch is employed to change between any of the three possible antennas which are now present – top bay, bottom bay, and both bays, each with differing radiation angles. This type of arrangement is employed at a local station, K9CSW. Here two three element duoband quads are stacked vertically, with the top bay at 77 feet, and bottom bay at 37 feet, slightly less than optimum for 20 meters, but decent on fifteen. Results have been somewhat encouraging, and appear to bear out the critical dependency on radiation angle that was hoped for. The bottom bay has no doubt made such a poor showing due to its close proximity to ground, surrounding it by the usual city clutter of wires and buildings. In addition, differences in excess of two S-units were noted between antennas during short skip (Sporadic E) conditions. This difference was in favor of a high angle over a low.

Sneaky stacking

A final method involves feeding the stacked antennas slightly out of phase with each other, thus raising the main radiation lobe. The advantage here is that the 3 db that may have been gained by stacking is always present, as was not the case in switching the antennas themselves. Fig. 9 is a theoretical example. For two stacked arrays, A and B, 3/4 λ or 270 electrical degrees apart, best results are achieved when both antennas "look" electrically identical and are fed exactly in phase, with precisely cut equal feedlines. This gives a low main vertical lobe; for simplicity's sake, we'll call it zero degrees to the horizontal. To raise this main lobe, the signal must reach antenna B before antenna A. For a rise of 10°, as illustrated, this required the feedline to antenna A to be longer than that to B by a distance D. Using simple trigonometry, dis-

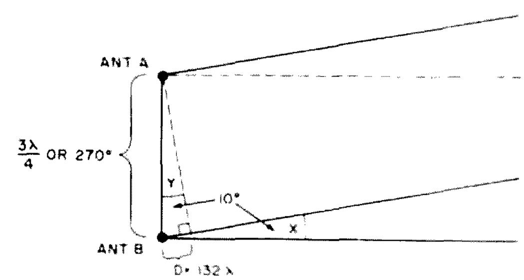

Fig. 9. To raise the main vertical radiation lobe in a vertical stacking situation, antenna A must differ in feedline from antenna B by a length D. Length D depends upon the desired angle x: here we used **10 degrees.** Angle y is also 10 degrees; therefore D is equal to tangent 10 degrees times the stacking spacing, or .132λ. (See Fig. 10)

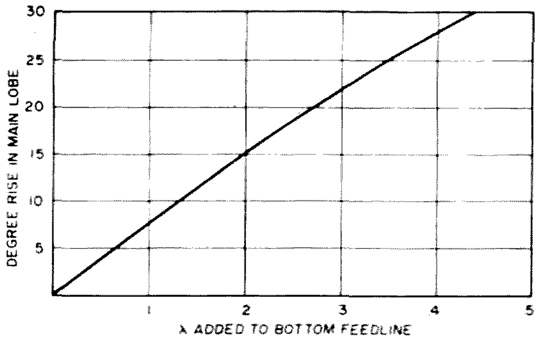

Fig. 10. Graph of wavelengths of feedline to be added to the top antenna in a stacking situation (Fig. 9) for raising the main vertical radiation lobe up to 30 degrees. This will only work for 3λ/4 stacking spacing.

tance D is found to be .132λ. To simplify things, this feedline difference has been plotted in **Fig. 10**. Note that this is only for a stacking spacing of 3/4λ.

A similar arrangement is being tried at K9CSW, with calculated switch positions of 10, 15, and 20 degrees, but results are a little hazy. Possibly the lobes are simply too broad to make a noticeable difference when shifted only a few degrees. Quads are partially stacked antennas themselves, so elevating the main vertical lobe any appreciable amount adds importance to usually insignificant side lobes. It's also quite difficult to keep two quads looking electrically identical for very long. One distinct advantage was noted here, however, over simply switching antennas. Some types of "city noise" apparently arrive at very distinct angles; manipulating the lobes in this manner often resulted in noise reduction on the order of two S-units. In some locations, this may be more valuable than any outgoing signal strength additions.

Conclusion – suggestions and more problems

The question I've still left partially unanswered is exactly what are the best angles? Bill Orr's *Beam Antenna Book* lists the range of optimum angle of radiation as in Table III. This is apparently inconsistent with those findings by Utlaut, (see **Fig. 1**) who found the very best angle to be the lowest tried, .7 degrees, much lower than the supposed 7 degree minimum. This was in light of the fact that the transmitting antennas in this case utilized realitively high angles (12 or 16 degrees) for main lobes. Although only listed for four months, Utlaut's signal strength versus time averages do show definite seasonal variations; low angles did seem valuable during a summer month (June or July) when the rule seemed the lower the better for the time the band was open. The spring months, however, pointed out the advantages in ability to vary the radiation angle, since higher angles dominated for much of the "band open" time. Results at K9CSW have varied, but seem to agree with this trend. Certainly an accurate yearly pattern could be worked out for a particular DX path, but the effects of other phenomena (sunspot number change, ionospheric storms, north-south tilts, etc.) that may be encountered along the variety of paths a DXer is interested in would make the game quite involved.

Band	Range of Optimum Angle of Radiation	"Optimum" Antenna Height
7 mc	12° – 40°	Above 45'
14 mc	10° – 25°	Above 40'
21 mc	7° – 20°	Above 38'
28 mc	5° – 14°	Above 34'

Table III. Geometrically determined "optimum" radiation angles for the ham bands. (4)

Another problem was encountered at K9CSW. Although signal strength differences were sometimes reported in excess of two S-units for one angle over another, it was rare when a same difference was noted on received signal strength. Apparently many DX paths are not completely reciprocal. This is a good thing or we might have to worry about accurately matching the DX station's vertical radiation pattern, but adds to the confusion when trying to decide which angle to use to be heard the best. Even in cases when signals received on both ends were enhanced, the difference was usually not detectible unless two-way key down S-meter tests were run. In contests or chasing a DXpedition, these key down tests are a little hard to come by; the need for some sort of system is apparent. Since accurate angle of arrival measurements are expensively complicated, perhaps only trial and error can devise such a system. It's hoped, however, that such a system actually exists, for it could pay off in great dividends for the serious operator, greatly adding to the effectiveness of even a modest antenna.

FSK Exciter

A couple of years of chasing out of tolerance ARC-5's used as vfo's ruled out that approach. And anyone who has tried building a vfo in the 3 to 7 MHz range will testify that obtaining a stability of 20 to 50 Hz is not the easiest of chores.

Some thought was given to shifting a vfo off frequency during standby, and this approach is very workable.

A better idea, however, was to borrow the basic concept from the Northern FSK keyer, which uses a 200 kHz oscillator beating against a crystal in a balanced modulator.

One item (available on surplus) which seemed ideally suited to the job at hand was the sub-assembly O-17-ART-13A.

This is a low frequency pto covering the range of 200 kHz to 600 kHz in three bands and is used in the AN-ART-13. The unit uses a 1625 tube, has a very fine, slow tuning dial, and is extremely stable.

(Note: If this pto cannot be obtained, don't throw out the idea. A 400 to 600 kHz vfo is not difficult to construct around a standard 455 kHz bfo coil, and stability relatively easy to obtain at this frequency.)

Since the pto would be the "variable" portion of the frequency control it seemed desirable to use it without modification. This could be done by shifting the crystal. It would minimize the unwanted frequencies if the exciter output were one half the transmitter output frequency.

Actual construction is straightforward and nothing is critical. Most parts may be freely substituted within a reasonably wide tolerance. The work and testing may be divided into four stages.

1. The power supply may be any 200 – 400 v source. 12 v is necessary for the heater of the 1625. The other tubes may be either 6 or 12 v types, depending on the supply. A VR150 and a VR105 or equiva-

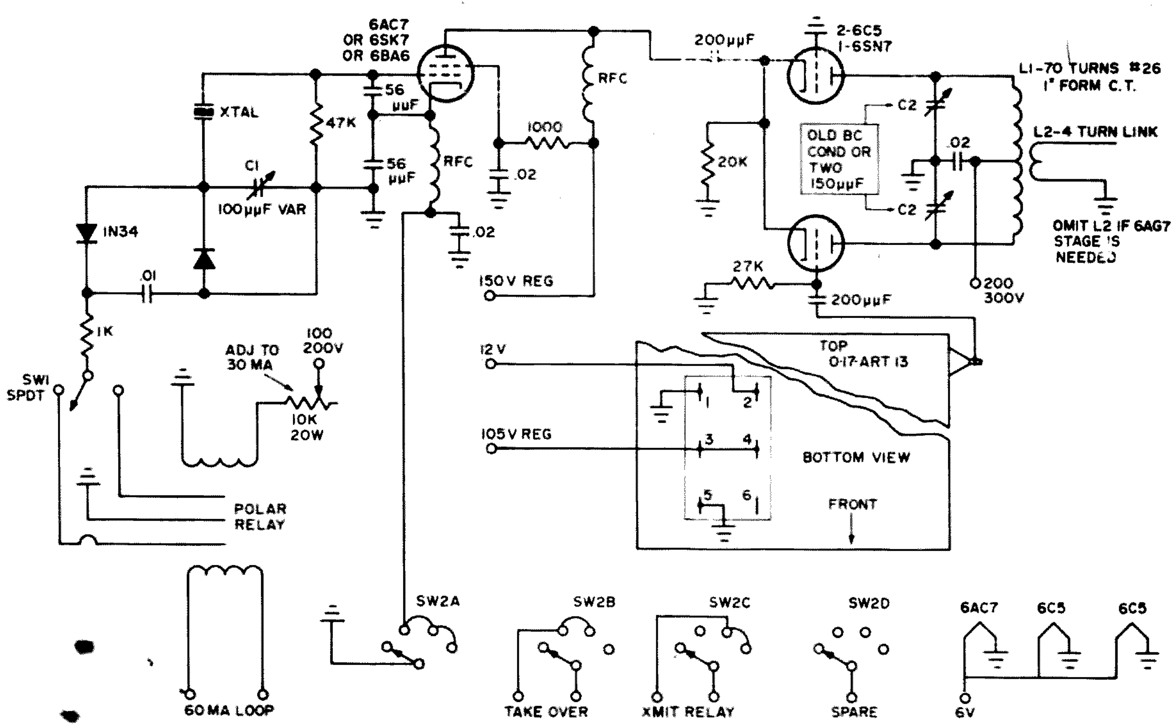

Fig. 1. FSK Exciter Schematic.

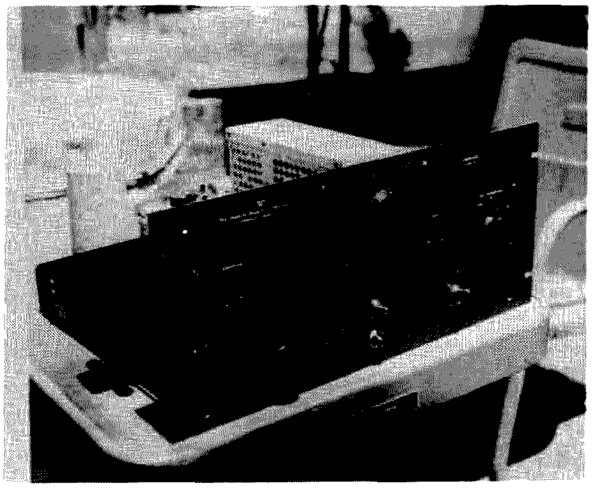


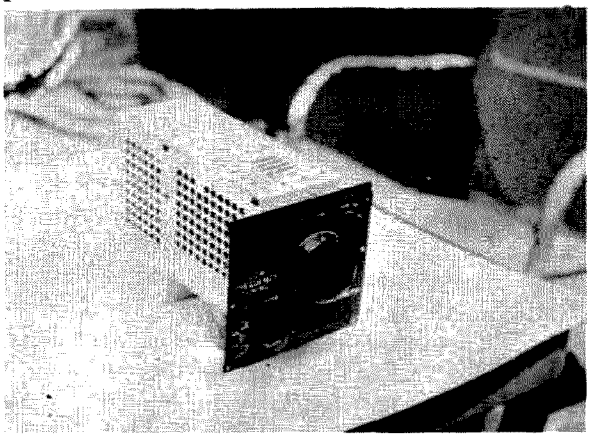
Complete exciter with pto.

lent regulator tubes should be used with the required dropping resistor (value depending on voltage). The O17-ART13 pto should not be used with more than 105 volts to minimize harmonic output. Once the power supply is assembled, the pto should be connected and checked by listening for its signal on the low end of the BC band.

2. Next the crystal oscillator should be completed. The only critical parts are the feed back capacitors from cathode to ground and from cathode to grid. The operation of the shift control may be checked by shorting across capacitor C1 with a screwdriver.

3. The two-triode balanced modulator requires no push pull input of any kind. The tuned circuit L1-C2 tunes the output range desired. Two separate condensers can be used for the sections of C2 if frequent frequency changes are not anticipated.

4. A polar relay is included in the keying circuit. With 30 mA bias current supplied from the exciter power supply, all that is necessary for operation is to plug into the local loop circuit. A turn over switch is provided.



The 0-17-ART-13 pto, available from Fair Radio for $4.00.

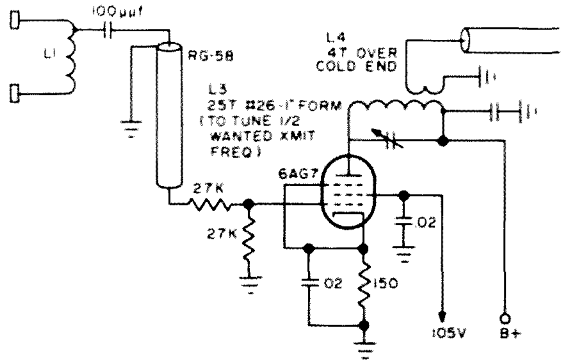


Fig. 2. 6AG7 Amplifier.

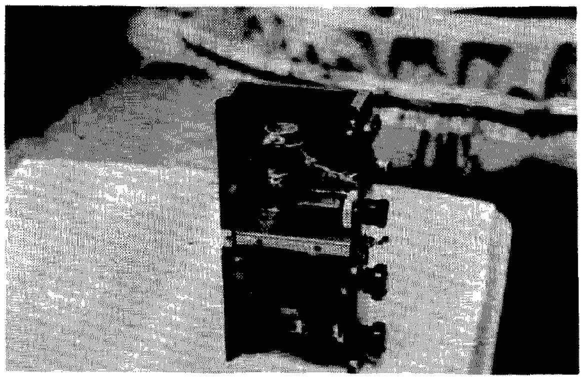

Fig. 2. 6AG7 Amplifier.

The function switch allows complete station control with one knob. In standby position the cathode of the crystal oscillator is lifted from the ground. In the take-over, spot, position the exciter is switched on by SW2-A while SW2-B shorts out the loop across the TU output. This prevents the receiver from keying the transmitter (if printer and keyboard are in series), and also allows a quick return of the printer to lower case by flipping the take over switch and punching the letters key. In the third position the "C" section of SW2 is used to control a transmit relay. In position No. 4 the short across the converter output is removed and the transmitter may be keyed by an incoming signal.

As with any hetrodyne circuit, care must be exercised not to tune up on a harmonic or wrong beat. The unit should be set up initially with a grid dip meter or absorption wave meter. The crystal used must be chosen so that the fourth or fifth harmonic of the pto does not fall on or near the wanted frequency.

By doubling in the transmitter any unwanted is further removed from the tuned output of the transmitter.

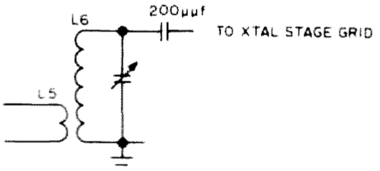

Fig. 3. Coupling coil to transmitter.

The average RTTY enthusist will devote long hours and careful planning to come up with the best possible TU. Then in a rush to get the rig on the air will, all too often, slap a diode shifter on any existing VFO – with less than the desired result.

Or, should he decide to shift a crystal he may spend hours grinding the rock to a net frequency only to find his shift shy of the 850 Hz. Not to mention the fact that the net frequency may change about the time he finally gets within tolerance.

In fact it was grinding my fifth crystal for Air Force Mars net operation in a little over one year that made me decide to do something, even if it were wrong.

Some Transmitters may require more drive than that obtainable from the balanced modulator. An amplifier stage becomes necessary. A 6AG7 is a logical choice. The grid of this tube is capacitively coupled to one side of coil L-1 through a short length of RG-58. Two or three turns should be removed from this side of L-1 to maintain balance. (If individual condensers are used for C-1, this may be maintained by tuning.)

The layout of the 6AG7 stage must be made with care. Some physical separation is desirable between the coil L-1, and the 6AG7 tube socket. The output coil, L-2, must be placed above chassis, (If L-1 is below) with the plate lead going directly topside from the tube pin. The 27,000 ohm resistor insures complete stability.

Low impedance output, either from the balanced modulator, or the 6AG7 stage, if necessary, allows the exciter to be located a convenient distance from the transmitter.

A tuned link coupled input coil should be used at the crystal stage of the transmitter.

Of the three FSK keyer units I have built, all have proved a pleasure to use. It has been found unnecessary to let the pto run all the time, as it will be well within tolerance from a cold start. And a five minute warm up will put you right on the button. The shifters have been used days at a time without touching the dial on Air Force Mars circuits.

So if you are having problems with drift, setting up and maintaining proper shift, or if you are simply tired of grinding rocks, the O-17-ART 13 pto shifter may be your answer. . . . W4LLR

The First QSL

Probably it was reading the ARRL quotation, "A QSL is the final courtesy of a QSO," which prompted me to dig into several hundred old QSL's in order to find out when and who started the "bloody mess." Unlike the story of the "Chicken and the Egg," there is no doubt that ham radio came first and that the art of QSL'ing was not far behind.

Apparently it started around the middle or the end of 1921. I was operating 1IV at Bridgeport, Connecticut, at that time and my first card came from E. Laufer, 2AQP, who reports hearing my signals on October 9, 1921, using a one tube regenerative receiver. This was followed by a QSL from J. E. Hodge, 4BY, dated November 10, 1921, and a report from Gerald H. Edison, 1BMY, December 30, 1921, asks, "What is your radiation current?" These QSL's are all written on penny postcards with the call letters put on with a rubber stamp or crayon. The first professional print job came to me from 2BRB (now W2BRB) and included a picture of the station. It is dated December 28, 1921, and most certainly Ed should be considered to be among the first of the QSL'ers.

By 1922 and 1923 the QSL business was booming. Fancy printed cards were replacing the home-made ones with everyone trying to outdo the other in splendor.

1923 brought the first of the DX cards. My first is from W. R. Burne, British 2KW, who received my signals on two valves, September 5, 1923, at 04.10 GMT; so to the British go the credit for being the first to use GMT on their QSL's, but no doubt their geographical location had something to do with this.

Just in case you think the "big boys" of that era were too sophisticated to QSL, you are wrong. I have a QSL from 1AW, signed by Hiram Percy Maxim; one from S. Kruse, 10A and 9ZN, R.H.G. Mathews. Others include John Reinhartz, 1QP; Irving Vermilya, 1ZE; Dr. Cyriax, 2DI; and, Leon Deloy, French 8AB. Even the famous 1BCG confirmed a QSO with me on July 29, 1923. 2BO—still going strong as W2BO sent me a card dated May 10, 1923, and says he is running 20 watts and using a paragon receiver.

I suppose we will never know who sent the first QSL card but we can pin-point the year as 1921 and what a lot of QSL's have been exchanged in those forty-seven years.

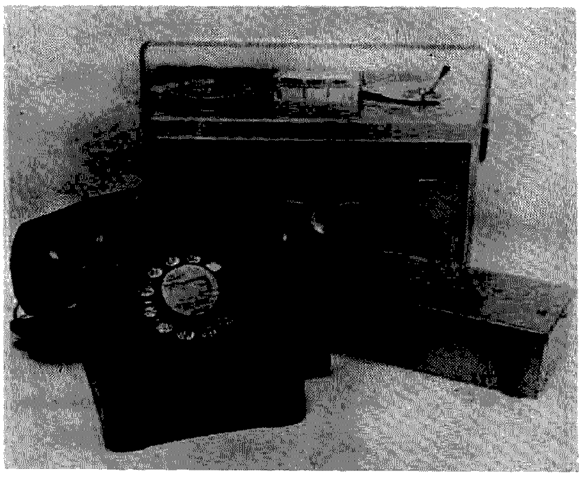
Telephone Beeper

Ed Marriner, W6BLZ
528 Colima Street
LaJolla, California 9203

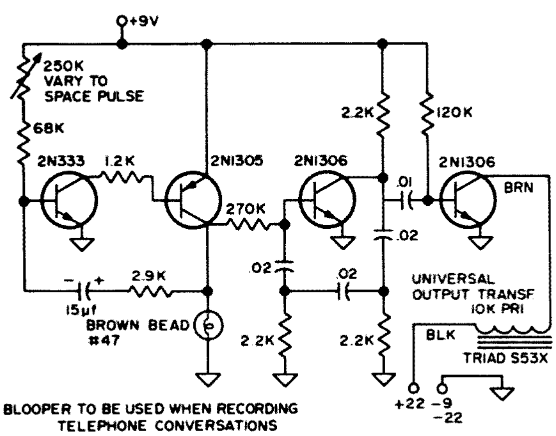


The following is a description of a telephone "beeper" to be used when recording telephone conversations. The "beep" can be adjusted to beep every nine seconds as required by the Public Utilities Commission.

Without going into the legality of the device, let's say it can be used to insert a beep into the telephone conversation that is being recorded, by inductively coupling into the telephone coil. The use of the device is visualized when recording phone patch traffic or recording a telephone message to be transmitted at some later time.

Theory

A 2N333 and 2N1305 transistor forms a multivibrator whose time of beep between pulses can be adjusted by a 250K potentiometer. The pulse stays on for one half second, allowing it to drive a 1 kHz oscillator much better than a saw tooth or unijunction type will drive it. When the pulse is too narrow the tone is not clear, thus experimentally the multivibrator was used.



Beeper to be used when recording telephone conversations.

A brown bead No. 47 lamp bulb acts as the pilot light and also as a non-linear element which helps to sustain reliable pulsing periods. The multivibrator drives a feedback type oscillator using a 2N1306 as the oscillator. This oscillator signal is amplified by a 2N1306 to create enough current through a coil to generate enough of a field to couple into the telephone instrument coil.

Construction

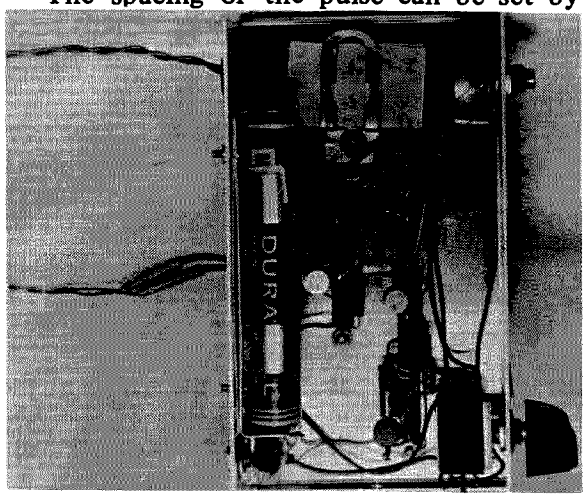
The "beeper" is built into an LMB type box, 3-1/2" wide, 2" high and 6" long. For simplicity the parts are mounted on terminal strips rather than on a printed circuit board.

Power is supplied from a 9 volt mercury type battery for long life, although, any 9 volt battery should last a very long time. The amplifier's source is 22 volts, which creates more current through the coupling coil.

Many types of coupling coils were tried, but an S53X output transformer seemed to work the best. The case was pried off and then the keeper or end of the core was driven off, using a hammer and screw driver. It was thought a stronger field could be obtained by sawing off one of the sides of the transformer to concentrate the field between the center and one outside core, but there was no difference in the coupled signal and it was not worth the effort.

There are no special precautions in wiring the unit except to get the polarity of the 15 mF condenser in the multivibrator circuit correct. If it is backwards, the oscillator will not work. An indication that the circuit is functioning can be determined by watching the lamp blink.

The spacing of the pulse can be set by



Note the battery mounting and parts installed on terminals.

turning the 250K poteniometer and timing it with a watch. A pair of crystal earphones can be clipped across the coil if it is desired to hear the tone, or the tone by induction into the telephone is another way to listen. The telephone coil is generally on the right side of the telephone as shown in the photograph. The transformer can be moved back and forth over the side of the phone until a maximum coupling is noticed and the transformer taped into place.

The circuit probably has other uses and comments might be suggested, but for our purpose it has served for inserting a beep into the telephone for recording. ...W6BLZ

(Continued from page 2)
of the bulging counters full of 19¢ pots, 5¢ tubes (guaranteed to light, play), and 29¢ tuning condensers.

Sideband came next and finished off the old surplus gear that was still working and most of the active amateurs made the move up to a transceiver...commercially made. Lordy, it would take a lab of test equipment to get one of those things working if you *could* build it. Even the servicing problems were getting beyond most of us by this time. How many fellows are going to go out and buy an oscilloscope and the other choice test gear needed to keep the modern transceiver working smoothly if they are going to use it only for an occasional service job? Virtually none, that's who.

This leaves us in the lousy position of not building our own equipment and not even being able to service it. Ham radio has come a long way. The old timers lament for the good old days, but no matter how loud their laments, they are buying just like the rest of us. Can anything be done about it? I don't know! Does anything have to be done? Has amateur radio changed so much that it is no longer worth keeping going?

What *are* the requirements for keeping amateur radio alive in our country? Let's take a look at the FCC regulations and see how we stack up these days as far as the purposes of the amateur radio "service" are concerned.

SUBPART A—GENERAL

97.1 Basis and purpose.

The rules and regulations in this part are designed to provide an amateur radio service having a fundamental purpose as expressed in the following principles:

(a) Recognition and enhancement of the value of the amateur service to the public as a voluntary non-commercial communication service, particularly with respect to providing emergency communications.

(b) Continuation and extension of the amateur's proven ability to contribute to the advancement of the radio art.

(c) Encouragement and improvement of the amateur radio service through rules which provide for advancing skills in both the communication and technical phases of the art.

(d) Expansion of the existing reservoir within the amateur radio service of trained operators, technicians, and electronics experts.

(e) Continuation and extension of the amateur's unique ability to enhance international good will.

The first, and presumably most important, function is (a) to provide emergency communications. I think we can do this all okay. There's nothing about building there.. For that matter, our commercial transceivers are vastly superior to home made equipment on several counts...easier to use...less down time ...anyone can use it...compact, etc. Old timers will tell you stories about the olden Field Days when fellows tried to tune and use someone else's rig and the troubles they had. My six-foot rack has been replaced by two small desk top boxes. And with about one amateur for every 800 people in the country we can provide emergency communications just about anywhere anytime. I think we should get a good high mark on (a).

Considering (b), it is difficult, of course, for even the above average amateur to try to compete with the well financed research laboratory for most development work. We can still compete with them when it comes to major break-throughs. Labs cannot possibly afford to spend a lot of money on something that does not have virtually a 100% chance of succeeding. We can. Fellows like Frank Jones, Bill Hoisington, Sam Harris, Bill Ashby and many others are doing work that is invaluable to our society...work that few labs would ever support. It is too bad that there are so few really outstanding men like this, but then, even in the past, there were only a small handful that made real contributions. I suspect that amateur radio is as valuable as it ever was in this respect.

(c) is very interesting. Verrry. Obviously, our incentive licensing rule changes reflect this aspect of the purposes of amateur radio. But have our rules really kept up with the technical end of things? Let us take another look back into our past at this time.

The first amateurs used the Morse Code for communications. It was considered difficult, at best, to modulate a spark transmitter, so code was the answer. Then came CW and the invention of the modulator, giving us AM. In

the 20's and 30's the phone transmitters were considerably more expensive than CW rigs and a lot more difficult to tune, with the result that most amateur operation was via CW. But, as soon as phone was available the hams started using it and the percentage of phone ops grew steadily. Most operators preferred to talk rather than whistle and they changed to phone as soon as they could afford it.

Sideband completely broke the back of the CW holdouts. Their complaints that CW could get through better than phone or that a CW rig was much less expensive than a phone rig fell apart. Sideband, they found, could get through just about any time that CW could! And the Heath $99 SSB transceiver forever stilled complaints about cost.

There are still a sizable number of ops that use CW because they enjoy using it, but few, except Novices, use CW out of necessity. With the percentage of CW operation dropping year by year, many have wondered just why the FCC added the 20 wpm requirement to the Extra Class license.

Modern communications techniques would seem to put emphasis on things like RTTY, facsimile, slow scan television, narrow band television, time sharing of channels, and other developments rather than harking back to our early days and our most primative mode. The FCC, to the contrary, has been decidedly backwards in handing down favorable rules for RTTY, facsimile, television, etc. Amateur development of these modes has been harassed and impeded by the FCC rather than helped, as per (c).

Part (d) calls for trained operators, technicians and electronic experts. We are concentrating more on trained operators these days than technicians. But, with some 10,000 of us active on the VHF's and a similar number working with RTTY and other advanced modes of communications, we are not doing too badly in the expert department.

Good will? With phone contacts as simple as they are today tens of thousands of DX operators can talk and make friends with fellows all over the world. A few simpletons yelling break-break, or calling doggedly on a DX frequency can create ill will, but for the most part, ham radio is a friendly world community. A recent report of the Stanford Research organization showed that, dollar for dollar, radio amateurs achieve more good will than short wave broadcasting...by a large margin.

We might try to curb our penchant for donating money to DXpeditions too. These often bring terrible ill will for us from abroad. The big problem is this: since the DXer is doing the job for money, he is very apt to by-pass a lot of formalities and tread heavily on toes in order to get on the air. One DXer went into Jordan a few years back and went on the air without a proper license. The result was that ham radio was finished there from then on.

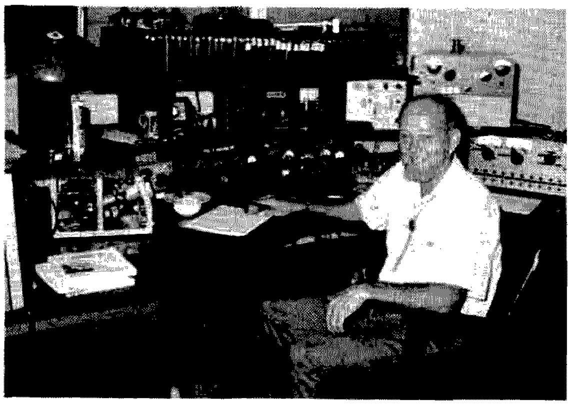
All in all, when you look over the FCC basis and purpose for amateur radio, we seem to still, in spite of all the changes that have come about, be well worth our salt. Perhaps those that are calling for a return to building should take a look at the balance sheet.

My own feeling is that building equipment is a lot of fun and I intend to run every construction project in 73 that I can get my hands on. Of course, I will tend towards pushing the newer modes such as TV, RTTY, SSTV, FAX, FM, and the like. We have a thousand or so hams that spend their hobby hours building equipment. Few of them ever get on the air for more than a short test of a new unit...then the parts go back into the junk box and the next project is underway. These are the fellows who provide us with most of the original constructions articles... this is why you keep seeing the same calls over and over in 73.

It is important for us to do everything we can to see that we constantly have new amateurs entering the hobby. A certain percentage of these newcomers will turn out to be builders...others will go for new modes...and a very few will get some sort of weird idea for a radical change and spend years working on it...and they just might succeed. I am reasonably sure that it won't be long until someone makes a gigantic breakthrough into another form of communications which will make radio obsolete. It could well be one of the Novices who will get his ticket this fall.

What do *you* think? ...Wayne

Recent Visits



Sam Harris, W1FZJ/KP4 runs the receivers down at the world's largest dish in Arecibo. Sam is active on 75M in particular, working DX along the low end of the band. He is also working on a miniature Arecibo dish at home, a few miles from the Big One. His 75M and 40M antennas are hanging from the three "haystack" mountains that surround his QTH.

Helen Harris, W1HOY/KP4 keeps her ear fastened to the receiver on six meters all day every day. She doesn't miss an opening if she can help it. If you're on six you've probably worked her by now. Helen has an incredible card index file of the thousands of stations she has worked on six meters so far. Note the 50 or so notebooks over the operating position!

Dick Spenceley, KV4AA is alive and well on St. Thomas. Dick is another who got off the DXCC treadmill when crossed up by Miller. He still keeps at it, but for fun now instead of blood. Does Dick have the world's best fist? Many think so.

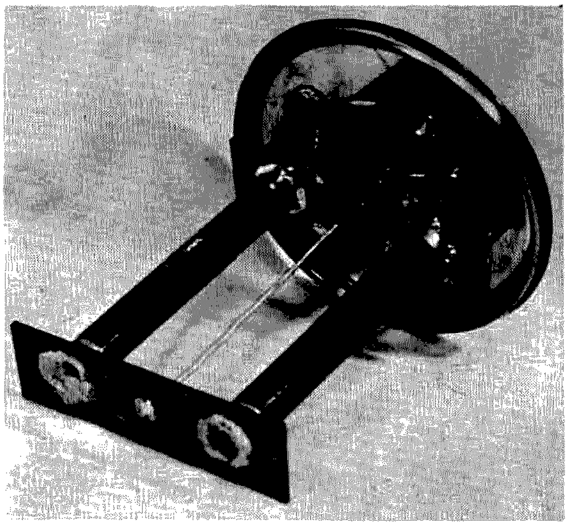
A Kilowatt Dummy Antenna . . . Cheap!

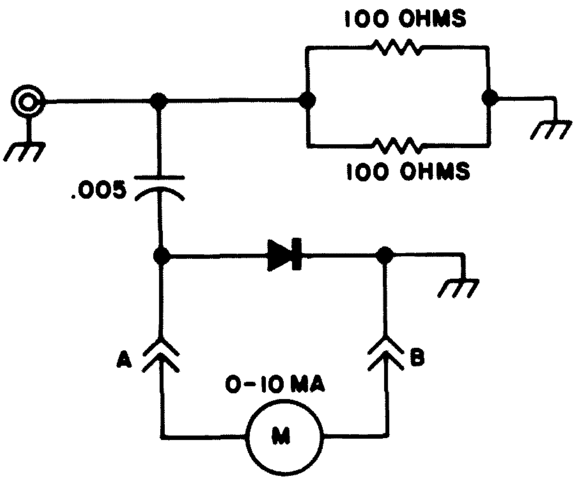


Allan H. Matthews, WB2PTU
R. D. #1
Waverly, New York 14892

This article describes a dummy antenna capable of handling one kilowatt, to be built at a cost of under \$4.00. In my case it cost \$1.53, but that was with a junkbox.

In a back issue of 73 (where else?), there were some 100 ohm, non-inductive resistors advertised by Mendelson Electronics, 516 Linden Ave., Dayton, Ohio. I ordered two of these at 50¢ each for my dummy load. When they arrived, they were 3/4 inch in diameter and 6 inches long, with both ends tin plated. I do not know the power rating of these resistors but they are more than adequate for our use. This unit will handle over 100 watts PEP with *no oil.*

The photograph tells the story. The top and bottom plates were cut to dimension, punched and drilled first. Next the resistors are fitted into the outside holes of these plates and soldered into place. I used 1/8th" double copper clad glass epoxy board and soldered the resistors to both sides of the board. Next run a heavy wire down through the center hole of the top plate and into the small hole of the bottom plate. Solder it on both sides of the plate. Center this wire in the top plates center 3/4" hole.



The next step involves a gallon paint can which can be purchased empty and clean at many paint stores for about 50¢. Punch the top of the can for a coax fitting, drill the holes to mount the unit inside the can and if you want a relative power output attachment, drill holes for the feed-thru terminals you will use. Also, drill 1 extra 1/16" hole in the top of the can.

Mount the top plate hanging down from the top of the can on 3/4" metal stand-offs. The resistors will clear the bottom of the can nicely at this height. Now mount your coax connector, your feed-through terminals and the other components in place and solder them. Run a couple of copper braids, (coax shield) from the top plate to the top of the can and solder them well on both ends. They will help to provide a low impedance ground path. The diode I used was of doubtful ancestry, but a 1N34A should do the trick. This relative output meter circuit allows use of a fairly heavy meter, dependent upon the power of the transmitter and the frequency of operation. A variable resistor across the meter will be an aid.

Now go to the power company and scrounge a gallon of transformer oil or fill the can with mineral oil, leaving about 1 and 1/2" of space at the top of the can. *Do not use motor oil!!* The extra 1/16" hole? Oh, that is to relieve pressure as the oil heats up. When not in use, plug it with a match stick or small bolt. Well, there it is, a kilowatt dummy antenna at a price everybody can afford.

...WB2PTU

One that Didn't Work Out

Don't misunderstand me. The home-brew coax switch I'm about to describe works fine. It just cost more than it should have, and it doesn't do quite all that a commercial unit does. If the purpose of home-brewing is to save money while producing gear equal or superior to commercial products, this project qualifies as a failure. Still, it may be of interest.

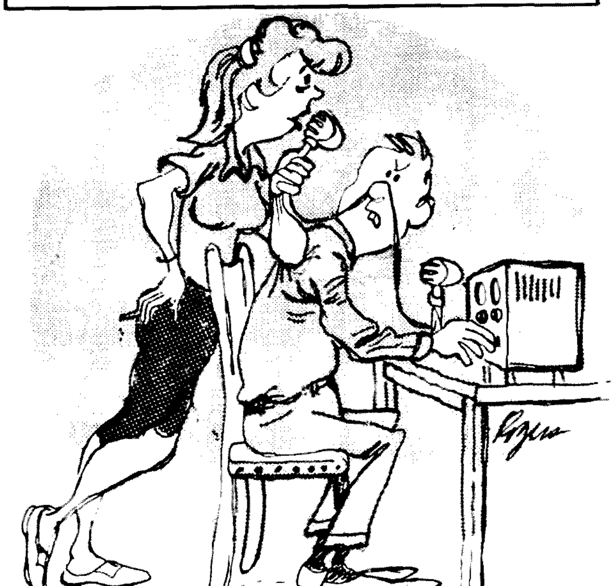
First, you take a cat food can—one of the little ones that contains the so-called "gourmet" cat foods. Open it and feed your cat the contents. (You *do* have a cat, don't you?) Then wash it—wash it *very* well. If you don't you'll have a very smelly coax switch!

Now, mount six SO-239 connectors equally spaced around the outer wall of the can. (Use the single hole mounting type if you can.) Drill a hole exactly in the center of the bottom, mount a six position ceramic switch with 60 degree indexing, and line up the contacts with the sockets. Note that in one position, there will be no connection, since one of the sockets serves as the input to the switch. Wire it up using short lengths of #12 wire. Cut a disc of flashing a little larger than the diameter of the can, and seal up the back by laying a bead of solder between the rim of the can and the flashing.

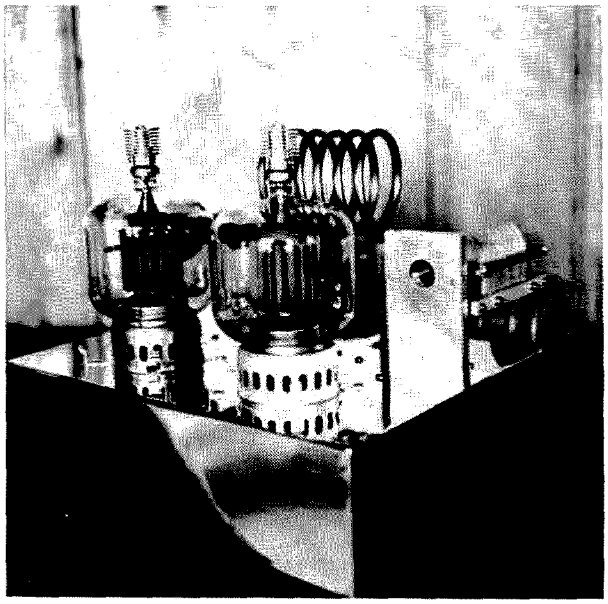
If you buy everything new, the switch will cost you five or six dollars. It doesn't ground the system in the "off" position, and it won't handle a kilowatt. For about five dollars more, you can buy a switch that does. However, crosstalk is low in the home-brew switch, and if you have enough coax connectors and a suitable switch in the junkbox, it may be up your alley. Works fine for switching between antennas, dummy loads, transverters, etc. If your junk box doesn't contain the necessary parts, take my advice—go buy a commercial unit.

There's a moral in this somewhere...something about the point of diminishing returns?

Bob Grenell, W8RHR



"OK, so tomorrow you get your own transceiver!"



Mini—Bomb

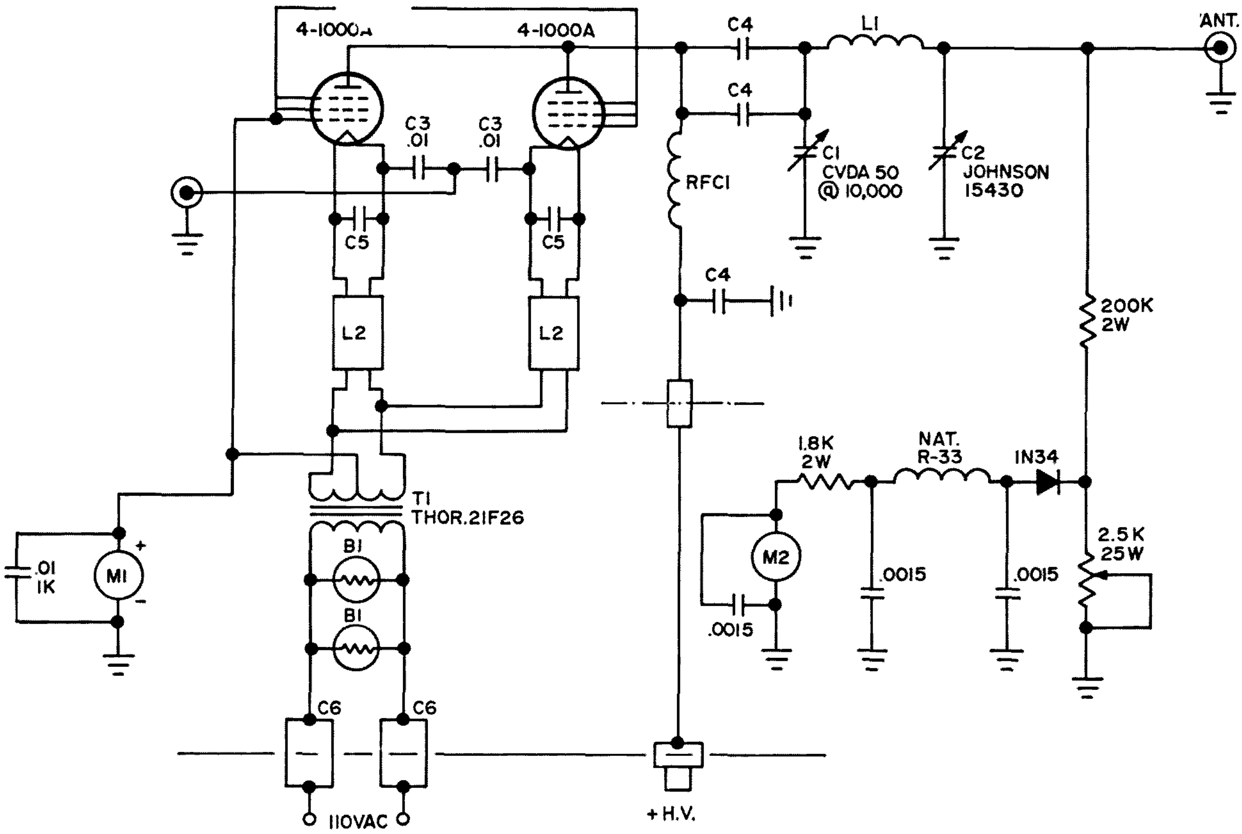
Bill Brown WφSYK
28 Marine Lane
Hazelwood, Mo.

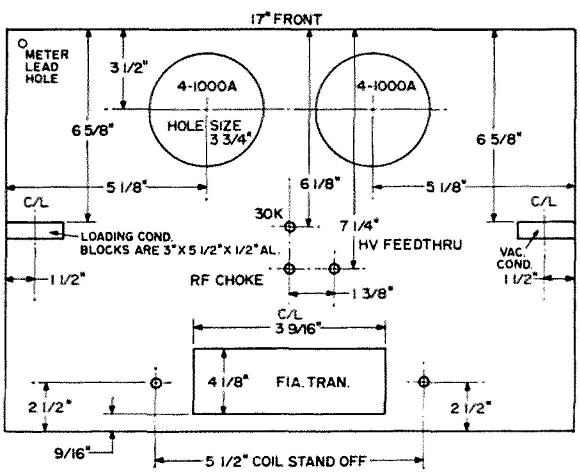
After many attempts to design a two tuber (4-1000A or 8166) on a standard chassis (13 x 17), I gave up in despair and went to a larger chassis which was 15" x 26" x 6" deep. An article was published in the May issue, 1965 called the "Big Bomb". I know of more than 30 Hams that are using this design.

The smaller rig got started one afternoon after finding a very small ceramic vacuum capacitor. After two days on the drawing board I finally got all the parts laid out without overlapping. Some features that might be of interest are as follow: Both plate and loading capacitors were mounted on 3" x 5½" x ½" Machine aluminum blocks, which will prevent current losses and will add to the high efficiency. Checks proved efficiency as high as 72%. I would like to call your attention to the high voltage feed-thru. These are home-made out of 1" round teflon extending 1" on each side of chassis. Breakdown was better than 30 K. Plate coil for 20 meters was formed on quart bottle of TANQUERAY gin (dia. 3⅝"), length was 5½". (Tubing ⅜" used). The design of the "Mini Bomb" is such that parasitic chokes are not necessary, and this final was checked for this with voltage better than 7.5 K. Chassis was chrome plated to prevent rusting and for appearance.

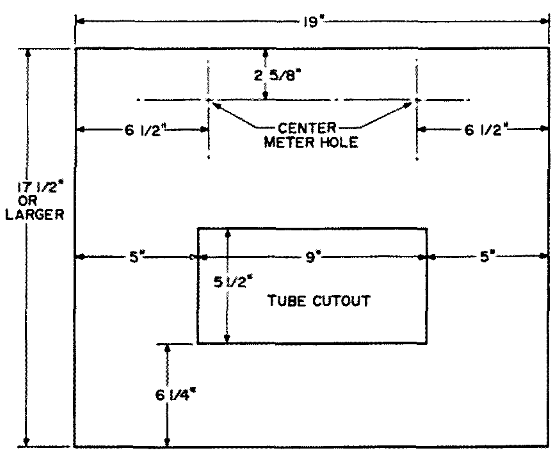
Since the tubes are in the front and centered on the chassis; a 6" x 9" cutout was made to view tubes. This cutout is 6½" from the bottom of the panel, which is steel, and 17½" high. Two meters (3½") were placed above the cutout. The plate meter is 0-1.5 amp. and the output meter is 0-1 mA with a 0-10 *rf* amp. scale being used. The large 3" Groth counter Dials rounds out the Panel.

This final is housed in a 61¼" cabinet with 24" depth, in order to make room for





MINI-BOMB CHASSIS LAYOUT



PANEL LAYOUT, MINI-BOMB

the blowers. The panel below is used for the *"wheel"* which is a Superior 28 amp. powerstat. The bottom panel is used for power supply, ac switches and pilot lights.

Power Supply

A real heavy duty power supply can be built for less than one hundred dollars. The plate transformer was purchased from the local power company for less than 20.00. The rating is 5 KVA @ 7200 volts ac. This will give around 6500 volts dc under load for the highest voltage. I like to operate with a voltage of 3700 using 100 watts drive from a Collins 32S-1. Two 550 mA UTC chokes are used in the negative lead. These chokes are in series with the swinging choke, followed by the smoothing choke. Solid state silicon rectifier were built up by using 48 (1 amp @ 1 K. Diodes) Oil capacitors were purchased from the power company also, at the rating of 2500 AC @ 7.5 mfd. Four units are being used giving a total of 30 mfd better than 7000 VDC at a price $5.00 per unit. A bleeder consisting of seven 10 K @ 200 watts resistors in series finishes the power supply. In closing, I have been using this heavy type of construction for the past 11 years without a single break-down of any part in this rig, Good DX-ing.

DX'ing from DL Land

Joseph D. Burnett, Jr., DL4BR
26 AEMS, CMR Box 4086
APO New York 09009

This is an American's view of what it's like to operate an Amateur Radio station in Europe. This is by no means a unique achievement–many hams who are in the Armed Forces are transferred to Europe each year, but I have never seen an account of their experiences in print. For those who are coming to Europe in the near future, this may serve as a guide of what to expect. For others who will never have the opportunity to sign a "DX" call, I hope this will be interesting.

I received notification of my assignment to Germany in January 1967, with instructions to report during the month of April. Along with finding out all I could about the base to which I would be assigned, I set about trying to determine what would have to be done to set up a ham station. Since all I had read concerning reciprocal licensing stressed contacting the agency responsible for the issuing of licenses in the country to be visited prior to arrival, I wrote to the Bundesministerium in Bonn, requesting information and instructions. I received a reply very quickly (via Air Mail), and the gist of the letter was that I would have to go through the Military Affiliate Radio System, since they serve as a liaison with the German licensing officials (the Deutsche Bundespost). After I arrived in Germany, things were a bit hectic, as in any move, but I managed to get to the MARS station on the base and fill out the necessary forms, and then a helpful clerk made the necessary photocopy of my Stateside license (for proof of license class), and the paperwork was set in motion. Red tape being what it is, it was about a month before I got my license. This cost $9.75 for one year–we get off cheap in the States!

Now to get on the air. I had been busy with moving into an apartment and getting settled, and so far had not erected any antennas. so I strung a twenty meter dipole across the apartment. My first contact was with UW1AC, 5-7-9, both ways. Not too bad for my haywire set-up, but I definitely needed something a bit better. After examining the situation I decided that to keep on good terms with the landlord (who lived immediately below us) and still radiate a signal, I'd have to hang something up in the attic. There are quite a few people in Germany who have large yards with lots of nice trees, but the majority of the people build their houses close to the street and turn the back yard into a garden. The housewives spend a lot of time keeping their houses and yards spotless and beautiful, and the gardens are right out of a picture. Our landlord and his wife were of the majority, and I wasn't sure how they'd react to an ugly pole sticking up out of that picture-book garden, with wires and cables hanging all over the place. So, what with the language barrier and a shortage of apartments I took the easy way out. Looking at it in retrospect, I think that if I'd brought a beam and tower here with me the landlord would have been more than happy to let me put it up, and perhaps even helped me with the installation. I have yet to find anyone who has had problems with a landlord here in Germany, except those who have made a nuisance of themselves with loud parties, etc.

Now, I had antennas for ten, fifteen and twenty meters (or indoor, air-cooled dummy loads, if you prefer), and I started operating. I was a little worried about the language barrier on the ham bands, but I needn't have been. English seems to be an almost universal language among hams. Naturally there are some mistakes in pronunciation or word usage, but the thought gets across, and that's what counts. I stayed in the DX bands at first, since that's where I expected to find hams who spoke English, but after taking a German conversation course I braved 3.5 MHz CW, using a matchbox and a hunk of wire; lo and behold, the same old abbreviations were in use there, and I felt at home almost at once. Unfortunately, too many of the QSO's I've had were of the "Hello, goodbye" type, but there were a number of ragchews both on CW and phone–something you don't have a chance to do very often when you work a DX station from the States.

The regulations governing amateur operation here in Germany are much the same as in the States, except for a reduced maximum power input and some of the frequency allocations. We are allowed only 500 watts dc input to the final: but that's not too bad, because there isn't the QRM level here that there is in the States. However, on eighty and forty the popular Heath single band transceivers are useless without modification (as

are some of the other transceivers). The DX bands are the same as in the States, but forty is only one hundred kilohertz wide, and eighty is three hundred kilohertz wide (7.0-7.1 MHz and 3.5-3.8 MHz). There is no official CW/phone separation of the ham bands here, but by gentlemen's agreement the lower one hundred kilohertz of each band is set aside for CW use; the exception being on forty, where the lower fifty kilohertz is usually CW only, but sometimes this varies with band occupancy.

TVI is not an overwhelming problem here as it occasionally is in the States. For one thing, the TV stations are controlled very closely, and have been set up for optimum coverage, thereby reducing or eliminating "fringe" areas. In my area the channels in use are 12, 14, and 40; and to get a harmonic into one of these, you'd really have to work at it. Fundamental overload is still a problem, but one that can be fairly easily corrected with a little cooperation. Even quiet hours are no great hardship, as the TV doesn't come on until early afternoon, and usually signs off before midnight.

Our AC power is 220 vac, 50 Hz, and it's fairly well regulated. There are transformers available commercially to step this down to 110 vac, and with few exceptions any gear designed for 60 Hz will work all right on 50 Hz without excessive transformer heating. Most of the better American manufacturers are providing export models of all their gear now, so if you're concerned about possible equipment damage this might be something to look into. I work in a test equipment repair and calibration facility, and to date the only problem we've had with transformer burn-out (due to line frequency) has been with some poor quality imitations of Tektronix equipment.

My pet peeve about my tour here has been (and is) QSL's, and the lack of them in my mailbox. I get a card out to each station worked, with one or two exceptions due to lack of address information, but to date, my return rate from W/K stations is just above fifty percent. I'm sorry to say that the return rate from DX stations is somewhat lower, but perhaps they have postal problems I'm not aware of.

This is not a complete picture of the American ham in Europe by any stretch of the imagination, but I hope you found it entertaining. If there are any questions, drop me an SASE, or look for me when the skip is good.

On the Use of Phonetics in Pileups

If you are among these fortunate enough to have a call sign like W6AA, you won't be interested in the rest of this article, but if you have one like WD2BJB, you may be interested to know what the DX'er on the other end of a DX contest pileup thinks of you if you say "Whiskey, David, the number two, 'D' as in Denmark, 'J' as in Japan, and 'B' as in Boston."

Some time in the nostalgic past when all call signs began with a "W" or with no prefix at all, it was an easy matter to decipher call signs. Today, with so many prefixes to choose from, we seem to have gone overboard in our phonetic frenzy to get call signs across.

Phonetics are to clarify, not to confuse, yet frequently we are apt to accomplish the opposite by employing certain techniques. In a hot contest or pileup, the object is to get as much information across in a short time as possible. Frequently in a contest, the contact is over while a slow caller is blissfully repeating his phonetics.

There are two things wrong with "Whiskey David, the Number two, Denmark, Japan, Boston." For one thing there are too many bits of information to remember, and secondly, remembering the proper order puts one more burden on the DX station.

Let's put yourself on the receiving end of a pileup. The important part is "DJB," the rest can be filled in at leisure after the contact has been established. What would you do if you were a WB2 and you heard the DX station announce, "The WB2 what was your call?" Immediately all WB2's are compelled to answer. However, "The station with call like DJB" immediately identifies you unless there happens to be a BJD, BGD, BJB, or some other phonetically similar call, a rare coincidence. If you go back in the face of such positive identification, you would be ostracized.

The important thing is to get at least two letters of your suffix across. If the DX station has any savvy at all, he will pry the rest of the information from you at his leisure. When the DX asks for a fill, give him only the information he wants. He asks for a fill because of QRM and not much else.

How effective is "Denmark, Japan, Boston?" After about 3000 contacts, the DX'er is a pretty weary fellow. After hearing "Denmark, Japan, Boston" he is liable to mutter to himself, "Now was that Japan, Boston, Denmark or Boston, Denmark, Japan?" By using phonetics you give him the extra task of trying to remember which word came before which. The order may be trivial to you, since you have practiced it many times, but the DX operator has heard that combination for the first time and he has to remember the order.

Just plain "WD2BJD" is apt to be more effective because it is easier to remember for the DX'er. He might have gotten it as "WB2BGB" but what does it matter? You've nailed him and can now correct him at your leisure. Better still you should say "WD2BJD, Baker John Dog" and *not* the reverse order, WD2 Baker John, Dog, WD2BJD. The worst of course is "William Dog, the number two, Baker, John, Dog." The DX'er now has to remember a Baker, two dogs, a John, a William and a two floating around some place and must place them in proper sequence. No wonder he mutters to himself.

Stick to plain WD2BJD, no phonetics until asked for. If the DX'er goes back to only those who give phonetics, he probably won't be a winner for his country because he is taking too much time per contact.

Going to the other extreme, I have heard something like "DJB, DJB, DJB" given with no prefix – "no nothing." This is especially pathetic to hear when he is the only one left calling after everybody has gone to the listening cycle. Giving the phonetics of the DX station is downright insulting. It is tantamount to telling the DX he doesn't know his own call.

"What's your number again?" may not be correct grammatically, but it is more effective than "I would like to have you repeat your number." Note "what is" (he wants

something so get set), "number" (it's my number he wants), "again," (he means repeat). The sequence is "get set" "for the query" "reinforce." This technique also works for copying high speed CW.* Note that in "I would like to have you repeat my number," the only part that carries information is "repeated number."

"William David Two Dog John and a Baker" is just as bad as "Kay Nine Dog and a King" (K9DK). The DX is apt to call you K9DNK. As my friend K4II says "If I send K4II "k" meaning "ar" on CW, I'm done for because they will insist on calling me K4IIK." This is just as bad as calling KH6IJ, K5BIJ, or KS6IJ on CW. I just can't shake them loose once the imprint is fixed, but on phone thanks to phonetics, corrections can be made.

Getting attention in a pileup calls for the skill of a seer. One must be able to place himself in the framework of the DX'er and be able to outguess the competition, and still not arouse the ire of the DX'er.

If you want to put these ideas to a test, come to Hawaii and operate in a DX contest. As for me, I don't care about fancy footwork, I just go back to the first caller I can make out who signs early.

Getting Your Extra Class License

Part IV — Radio Waves

The whole purpose of radio is to communicate, and to do so requires that information be transmitted from one place to be received elsewhere. The difference between radio and other forms of communication is that, in radio, we transmit this information over "radio waves" rather than by means of wires or the printed page.

To use radio for communication we must have some knowledge of the way in which radio waves work, and so the Extra Class license examination includes a number of questions to test your knowledge of radio wave propagation.

In fact, it includes too many such questions to cover adequately in a single installment of this series. This month we'll look at the general principles involved, and some of the more unusual aspects of VHF propagation. We'll handle the following questions from the FCC study list:

48. How do the directivity of an unterminated "V" antenna and a parasitic beam antenna compare?
58. What are aurora-reflected VHF signals? If such a signal is heard, what does it sound like?
67. What constitutes a parasitic antenna element?
71. List some different types of beam antennas.
76. What determines the skip distance of radio waves?

As usual, we'll extend the scope of these questions to cover the subjects more fully. For a start, we'll examine the whole problem by asking "What Is Radio Communication?" We will find, while exploring that subject, that signals are both radiated and reflected in the process of being used to communicate.

Our second and third questions will look in more detail at reflection, by asking first "How Does Signal Reflection Occur?" and then "How Does Reflection Affect the Signal?". The answers to these two questions will include the unusual VHF effects, and will also help us meet the final two questions.

Our final two questions will bring us into the area of signal radiation: "How Is a Signal Radiated?" will introduce the subject of antennas in general; "How Can a Signal Be Concentrated?" will focus our attention on directive antennas.

While we'll get no farther in this month's instalment, future discussions will extend our study of antennas in the same direction.

All set? Let's dive in.

What Is Radio Communication? It may seem an overstatement of the obvious to proclaim that the whole purpose of radio is to communicate – yet many of us are so involved with the purely technical aspects of radio and electronics that we tend to lose sight of this basic fact. For this reason it's worth while to stand back at this point and try to find out just what is involved in communication by radio – or "radio communication".

Let's try to find out what is involved by doing some "word substitution". What we want to know is simply "What Is Radio Communication?" If we can substitute other words or phrases for the words "radio" and "communication", we may have a meaningful answer.

We'll tackle the hard one first – what can we put in the place of "communication"?

This is hard because the question of what constitutes communication has been stumping the experts for years, and promises to continue doing so for some years to come. About all that they agree on is that communication involves a "transfer of information" – so let's try that on for size.

"Radio transfer of information" still seems to make sense although it doesn't tell

us much more. Let's use that and try to keep going along this route. What can we put in the place of "information"?

Some 20 years ago, fortunately, Claude Shannon found a good answer for that one. He defined information as "a selection from a set of possible choices", and went on to define it more precisely as a reduction in the uncertainty of the selection. However when we plug in Shannon's definition of information the result looks more like a government directive than like any meaningful explanation. Let's try again, using Shannon's idea but not his words.

The simplest possible amount of information about anything is the mere fact that it exists, or does not exist. This is an all-or-nothing choice with no alternatives – and we make use of it any time we send a message using CW. The carrier is either there or it is not, and we interpret the pattern formed by its presence or absence over a period of time into characters of the alphabet which spell out the message.

Following this line of reasoning, the carrier is a radio wave and a radio wave is a form of energy. It's not unreasonable to say, then, that information *can* consist of a sequence of energy patterns. It's not even unreasonable to assume that it always consists of such a sequence of energy patterns, because an AM signal or even TV is also a sequence of energy patterns – just much more complex than the simple on-or-off of a CW signal.

And plugging this in gives us the phrase "radio transfer of a sequence of energy patterns", which doesn't seem to be too far out although it does tend to sound more like engineeringese than like English. Let's see what we can do about that.

The word "transfer" always implies a "from-to" relation; that is, it means a movement of something *from* a source or transmitter *to* a target or receiver. Let's use this fact to modify our phrase even more: "radio movement of a sequence of energy patterns from a transmitter to a receiver" is the result, and it sounds more like English if we turn words around a little to say "movement of a sequence of energy patterns from a transmitter to a receiver by means of radio".

What's more, this expansion of the simple phrase "radio communication" is beginning to look almost like a definition, which is what we set out to find!

About all we have left to do to it is to expand the word "radio" and we may have our answer.

The physicists tell us that any energy can be moved by two routes – conduction and radiation. Conducted energy moves along some physical "conductor"; direct current flowing in a copper wire is an example of conducted energy, and so is light flowing through a polished plastic rod. For that matter, the heat reaching the handle of a skillet gets there by conduction too.

Radiated energy, on the other hand, moves directly through space without benefit of a conductor. The light and heat from the sun are good examples of radiated energy. So is the *rf* output of any transmitter once it leaves the antenna. The word "radio" is, in fact, simply an abbreviation of the word "radiate"!

So we can define "radio communication" as being "movement of a sequence of energy patterns from a transmitter to a receiver by means of radiated energy". This gets us the answer to our first question, but there are a few points to clear up before we move on to the second.

For instance, the "transmitter" in the definition we have just developed is not what we generally mean when we use the word. In this definition, a "transmitter" includes the entire setup from operator and mike or key, through the transmitting equipment, to the antenna. Similarly, the word "receiver" in the definition includes the receiving antenna, receiving equipment, and finally the receiving operator. After all, communication is established only when something gets from one human brain to another – you can't do much communicating with a beacon or code wheel!

And the use of the words "radiated energy" in the definition doesn't mean that some conductors aren't involved too; the point here is that the major part of the transfer is done by radiation. We all know that any radio equipment is full of wires. The story is told of a British dowager in the early days who, upon being shown a "wireless" station, asked "Why do you call it wireless? I've never seen so many wires before in my life!

In fact, communication by radio involves the use of both conducted and radiated energy. The transmitting equipment originates the *rf* energy and puts the sequence of energy patterns into it, and all during this phase the energy is conducted by our wires and feedlines. If any of it *does* radiate at this

stage of the game, it's a major problem! That's what shielding is all about.

The antenna is the bridge between conduction and radiation. At the transmitter, the energy is conducted to the antenna, and radiated from it. At the receiver, the antenna picks up the radiated energy, and the energy it receives is conducted into the receiving equipment.

So long as our *rf* energy is being conducted, it follows most of the normal rules which apply to dc and low-frequency *ac* (with a few exceptions such as skin effects). When it is radiated, the special rules which apply to radiated energy get into the act.

It might appear most logical to move from here directly into our examination of the bridge between conduction and radiation, the antenna. However, action of many types of antennas involves the rules of radiated energy rather than those of conduction, and so is easier to comprehend with a knowledge of these rules. For that reason we'll examine the rules of radiated energy next. Then we'll move on to look at the antenna situation.

How Does Signal Reflection Occur? Reflection of a signal is just one of two effects which occur when radiated energy meets anything. To find out how a signal is reflected, we must examine the way in which radiated energy interacts with anything it meets.

It's easiest to understand by keeping in mind that *light* is also radiated energy; any rule followed by an *rf* wave must also be followed by light, and any rule obeyed by a light beam must also be obeyed by *rf.*

It's also important to keep in mind that the rules which determine action of waves, while simple enough in themselves, are at the very heart of all modern physics. Most engineering textbooks make no effort to explain the rules – they merely state that the rules are followed.

One volume which does attempt to explain them in detail (Fields and Waves in Modern Radio, by Ramo and Whinnery) makes generous use of matrix algebra and differential equations derived from Maxwell's Equations to present the explanation.

But we're not afraid to take a chance on oversimplifying a complex subject in the interests of getting the main part of the idea across; we may make a few minor errors along the way but in general the following explanation is how it works.

And you won't find the slightest trace of mathematics in it, either.

A word of warning is in order, however. While the main idea is presented accurately, don't get into any arguments with physicists and cite this material as your reference. It may not be all that accurate; in case of conflict, believe the physicist!

If you're still with us, then, let's dive right into just how "wave mechanics" and "quantum theory" describe the interaction of radiated energy and matter.

While nobody yet knows exactly what a "wave" of radiated energy amounts to or just how it manages to get from here to there, a number of ideas and concepts (the big brains call the "models") have been developed – and most of them seem to fit at least parts of the needs pretty accurately.

One of these ideas, which is the basis of quantum theory, is that a wave consists of minute packets of energy called "photons" and that the amount of energy per packet is related to the frequency of the wave. The higher the frequency, the more energy per packet.

In this scheme of things, a light wave packs more punch than does a radio wave, and an X-ray has more punch than either.

The effects which we observe in waves, such as those of reflection, refraction, diffusion, or scattering, occur only at the boundaries where the wave moves from one substance to another. So long as a wave is travelling in a single medium, whether that medium is air, a sheet of plastic, glass, or the unknown substance today's scientists call merely "space" and the learned men of an earlier era knew as the "aether", it can produce no observable effect!

At the boundary which separates one medium from another, though, one major effect occurs. This effect shows up as two distinct phenomena – and it's only because of them that we can tell that waves exist.

The effect which occurs is an interaction between the wave's energy and the particles which make up the medium; normally these particles are atoms, but sometimes they are molecules and in a very special case they include electrons as well.

The particular type of interaction which occurs depends upon the relationship between the frequency of the wave and the self-resonant frequency of the particles involved. Each of the particles of atomic or molecular size *does* have a self-resonant frequency, and it's most convenient to think of them as being tiny tank circuits exposed

to an excitation from the incoming wave.

If the incoming wave is at a frequency far below that of the particle's resonance, the particle will vibrate weakly in phase with the incoming wave.

If the incoming wave is at a frequency far *above* that of the particle's resonance, the particle will still vibrate weakly at the frequency of the incoming wave, but its vibration will be 180° out of phase with the incoming excitation.

If the incoming wave's frequency matches that at which the particle is resonant, the particle will vibrate strongly, 90° out of phase with the incoming wave.

In most materials the particle resonances are at frequencies higher than that of visible light; a few substances have resonances as low as the infrared region, but almost none have resonance in the common *rf* range.

For this reason, for most *rf* energy and almost all materials the first case will hold true. Each particle at the boundary of the material will vibrate weakly and in phase with the incoming wave.

There's a very special exception which we will meet a little later, in which both in-phase and out-of-phase vibrations occur. Before we look at that, though, let's stay with the first case and see what happens most of the time.

Now as it happens, a vibrating particle will itself emit new radiation just because it's vibrating. It's the same basic idea as that of the tuning fork, which you hit to make vibrate, and which then emits an audio wave because it is vibrating.

This means that when an *rf* wave hits the surface of any substance, each particle at the surface of that substance will re-radiate new waves which are in phase with the original *rf*

Each of these new waves will, in turn, hit adjacent atoms or particles within the material and cause additional vibrations and more re-radiation.

If the particles are scattered about the substance more or less at random, as they are for instance in a gas, the total effect of all this secondary vibration will be a "scattering" or "diffusion" of the original wave. The higher-frequency waves in the original energy (if a mixture of frequencies were present at the start) will predominate in the scattered new radiation, because they had more energy per photon to begin with.

We see such an effect any time we look at a blue sky. The blue skylight is the scattered

re-radiation produced by the molecules of the air when they are hit by sunlight; the red of the sunlight is dissipated in the scattering process.

If the particles are held in a reasonably rigid structure, though, as they are in most solids, the effect of the new radiations is rather different.

All of the individual re-radiations from the individual particles tend to cancel each other out, because the particles are regularly spaced. The only re-radiations that are not at least partially cancelled by this effect are those which happen to add up in "coherent phase" travelling in just one direction inside the material, and those from the surface layers of particles which have no other particles above them to produce cancelling re-radiation.

The new wave inside the substance is known as the "refracted" wave. It may move at a different speed than did the original, and in a different direction as well, depending entirely upon just how the particles of the substance are arranged in their rigid structure.

The particles at the surface (a layer about half a wavelength deep) are producing re-radiation in all directions. These re-radiations all interfere with each other, just as do the cancelling ones inside the substance, but just what happens when they interfere depends upon the structure at the surface.

If the surface of the material is smooth (using the wavelength of the incoming radiation as the yardstick to determine smoothness; anything with irregularities no more than 1/10 wavelength apart is considered "smooth"), then the radiations from the particles at the surface will interfere with each other just as do those inside the material to produce a single wave travelling in a single direction.

The interference is normally such that the new wave from the surface particles – known as the "reflected" wave – leaves the surface at the same angle with which the original wave arrived, but in the opposite direction. This is the classic law of optical reflection as shown in Fig. 1.

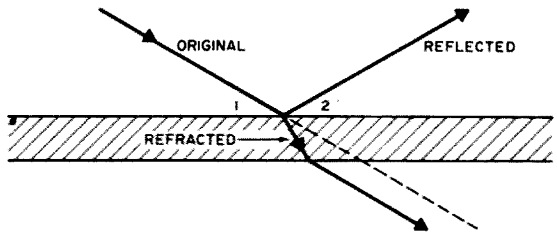

Fig. 1 — Classic optical example of reflection and refraction shows that reflected ray always leaves surface at same angle it arrives. Refracted ray changes direction at boundary. If refracted ray passes through another boundary, as shown here, its direction changes again; if two boundaries are parallel to each other final ray will be parallel to original ray (dotted) but offset from its path. If boundaries are not parallel, as in a lens, rays may be either spread apart or focussed to a point. Same effects are present in radio waves but because wavelength is much larger the effects show up somewhat differently.

If the surface is rough (irregularities more than 1/10 wavelength apart), then the reflected waves from each surface particle will not add up to a single wave since each will have travelled a different distance at any given point away from the surface. Reflection still occurs, but it is diffuse rather than sharp. A white cloud offers an optical example of this. So, for that matter, does the white surface of the paper on this page; the paper particles are much larger than the wavelength of light, and so the light falling on the page is reflected diffusely. Where the ink is heavy, it forms a coating with a surface structure smaller than 1/10 wavelength of light, and so appears glossy with sharp reflections.

Since both light and *rf* waves are the same type of electromagnetic radiation, differing only in frequency, *rf* acts just the same way light does. The apparent differences are due to the vast difference in frequency; a structure which is quite smooth to an *rf* wave may consist of such widely scattered particles that it appears totally transparent to light. A screen-wire reflector is a good example of what we mean here. Another example is the ionosphere, although its relative smoothness differs for *rf* of different frequency.

Because of this, when a radio wave hits almost anything both reflection and refraction will occur. The reflection is the basis for radar, and the refraction makes skip propagation possible (as well as possibly providing the mechanism for radio to exist in the first place, if you consider the "radiated" wave as being refracted through space).

But before we go any further we must examine the very special case of materials which are electrical conductors, because they behave rather differently than the ordinary solid substances we have been examining.

an insulator lies in the atomic makeup of the

material. A conductor contains numbers of "free" electrons which are bound only loosely to their parent atoms and which are free to wander about the interior of the material under the influence of electric forces. A perfect insulator has no such electrons, and actual insulators have very few.

The free electrons in a conductor provide the means by which an electric current is conducted, and also make a large difference in the action of the material when a wave hits it, because both the free electrons *and* the particles which make up the substance's structure at the atomic level vibrate.

The particles vibrate weakly, in phase with the incoming wave, just as do those of insulators. The free electrons, on the other hand, vibrate *out* of phase with the incoming wave by 180°, also weakly.

The vibrations of the free electrons cancel out the vibrations of the particles, and make it impossible for the wave to penetrate the boundary of the substance. Refraction cannot occur, because the energy can't get inside the material.

But the energy is still striking the surface, and the surface layer of particles is still vibrating. This permits reflection to occur. What's more, the law of conservation of energy requires that all energy going into something must come out again – and since no refraction can occur, *all* the energy taken from the incoming wave is reflected from the surface.

Thus a conducting surface will reflect all the *rf* which hits it, while an insulating surface will reflect only a part and will refract the rest through itself.

Conducting reflectors play a large part in antenna design; the principles of reflection (particularly that of re-radiation) are also important in understanding action of parasitic antennas.

The effect normally known as "signal reflection", though, is more often actually due to refraction than to reflection. Such things as skip transmission, meteor trail communication, and aurora-reflected signals are actually effects of refraction. Moonbounce and scatter work, however, are true reflection phenomena.

The reason why refraction can masquerade as reflection is illustrated in **Fig. 2**, which shows refraction at work in one of the ionized layers responsible for skip transmission.

When a wave is refracted, both its speed

and direction usually undergo change. Speed may either increase or decrease; the change of direction usually depends upon what happens to the speed.

If the refracting medium has characteristics which change gradually within the material, the speed and direction of the refracted wave will also change gradually as the wave proceeds in the material.

The ionized layer is such a medium; its makeup changes – both from minute to minute (and other periodic changes) and at various points within the layer at the same time.

Thus a wave transmitted from the earth will be bent or refracted only slightly as it enters the ionized layer, but the deeper it penetrates into the layer the more its direction is changed. When the original direction has been changed enough to turn it around a corner, the wave is moving out of the material rather than in, and then the change in direction becomes less the farther it travels.

Eventually the wave will come back out of the layer, provided that the refraction doesn't just happen to trap it completely within the layer and bend it only enough to keep it trapped. Even if this should happen at some spot, there are enough irregularities in the layers that the energy would escape elswhere – and such an action may be at least partially responsible for some types of fading.

As Fig. 2 shows, when the wave emerges from the layer there is no way at all you can

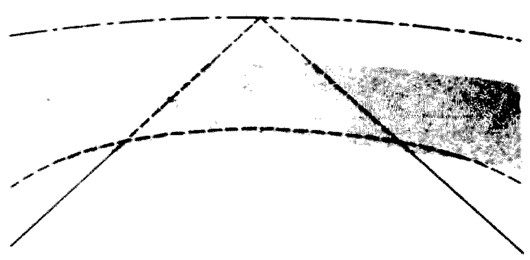

Fig. 2 – Refraction of radio wave in ionosphere is cause of apparent "reflection" of skip signals as shown here. Since ionization level changes gradually within an ionized layer, angle of refraction is continually changing. This bends wave back in new direction, making it appear to have been reflected from a surface at somewhat greater height (dashed line). Wave reaching layer at shallow angle (dotted) does not penetrate so deeply as one hitting at sharp angle (solid); therefore it is bent less and so returns to earth at greater range than difference of angles alone would indicate.

determine that it wasn't simply reflected from a sharp surface at a somewhat greater height. This fictional reflecting surface's height is what is referred to as the "virtual height" of the skip layers.

The reason we know it works by refraction rather than reflection is that the virtual height of a layer appears to change with the angle at which energy hits it. The shallower the angle, the lower the virtual height. You can see from the dotted-line example in **Fig. 2** that this would be expected with refraction, but not with reflection.

This mechanism in the ionisphere indicates that the angle at which the signal will be "reflected" depends critically upon the angle at which the signal arrives, and also upon the condition of the ionized layer at that particular time. High-frequency signals packing more punch per photon, bore right on through much more readily than do those of lower frequency – so that as you keep going up in frequency, you find a point at which the signal simply doesn't come back down. Instead, it bores on out headed toward outer space.

The angle at which the signal hits the layer depends, in turn, upon the actual angle at which the wave leaves the transmitting antenna. This depends upon the antenna design, its height above electrical ground, and the nature of the ground surface within several wavelengths of the antenna site. The lower the angle at which the signal leaves, the more shallow will be the angle at which it hits the refracting layer, and the greater will be the distance covered before it returns to earth.

Any substance which is capable of refracting the wave can cause "reflection" by refraction in this same manner. In addition to the horizontal ionized layers which make up the ionisphere, *rf* signals are frequently "reflected" from the aurora borealis and from the trails of ionization left behind by meteors. At VHF, similar effects are caused at the boundary between different layers of air in the atmosphere.

How Does Reflection Affect the Signal? True reflection has virtually no effect upon the signal, except that its phase changes 180° during the process of reflection. "Reflection" by means of the refraction effect, though, can affect a signal in many ways.

Reflection of VHF signals from the shimmering veils of ionization which are known to science as the aurora and to the general public as "the Northern lights" offers several examples of such effects.

The aurora is a rapidly moving affair. Its

exact cause and composition is still not accurately known, but it is believed to be especially intense ionization of the upper atmosphere under influence of solar radiation trapped by the earth's magnetic field. It is visible as curtains, columns, and sometimes horizontal sheets, and moves in both the horizontal and vertical planes at relatively high speeds.

Often, the aurora appears to shimmer with a to-and-fro motion.

Any radiation reflected (that is, refracted back toward the source) from these clouds has a frequency shift imposed upon it by the motion of the clouds, by Doppler effect.

This frequency shift is, effectively, FM of the original signal, in which the modulating signal is the oscillating movement of the aurora itself.

The frequency of the aurora's oscillation is often so great that the resulting FM completely wipes out any intelligibility of audio upon the signal, and makes a CW signal appear to occupy a wide band rather than the normal near-zero bandwidth.

If aurora-reflected signals are received by the normal CW method, using a product detector or BFO, the FM causes the received signal to appear to warble. But since the reflection is coming to the receiver from a wide source – the entire aurora cloud – and part of it is moving toward the receiver while other parts are moving away, it isn't just a single warbling note. Instead, it's a mixture of frequencies covering the entire audio range. The resulting sound has been compared to the whine of a buzz saw going through a pine knot . . .

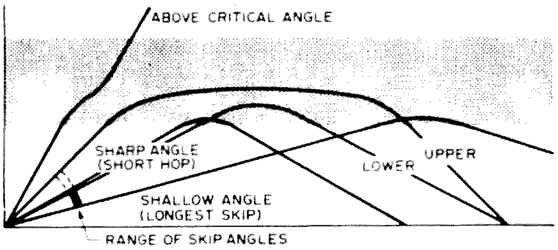

Fig. 3 – Various effects of transmission angle (angle at which wave leaves transmitter) are shown in this sketch. The longest skip distance is achieved by the wave with the lowest transmission angle, and the shortest by that with a moderately high angle. As angle increases, wave is held in ionized layer longer and skip distance increases again. Such waves are called "Pedersen waves" and may interfere with lower waves from same transmitter as shown. Still greater angles permit wave to pass on through ionized layers if ionization is sufficiently weak.

Just to complicate things, most aurora-reflected signals are very weak; very little of the original signal is reflected to any one receiver. The signal-to-noise ratio is often as low as zero db.

Somewhat the same situation prevails when the trail left by a falling meteor provides the refracting ionization. In this case, though, the warble is absent. Any Doppler shift is usually constant. Signal levels, however, are much lower because the refracting volume is much lower.

Scatter techniques depend more upon true reflection, of the same type that makes an oncoming automobile's headlights visible over the rim of a hill on a foggy night. The original signal is reflected in all directions by tiny discontinuities in the atmosphere (tropo scatter) and ionosphere (ionospheric scatter). Scatter transmission provides the most reliable and consistent form of long-distance *rf* communication, but requires power levels greater than those allowed the ham by law to attain reasonable distances with high reliability. At amateur power levels, distances are so short that most scatter signals are thought to be "ground wave" instead.

All of these effects are present with all radio frequencies, but their effectiveness varies with frequency. At moderate frequencies (15 meters and below) they are usually overpowered by "normal" skip transmission. In the VHF range they are most observable, and many VHF operators specialized in using one or more of these techniques. As the frequency goes on up, the amount of refraction becomes too small to return a usable signal level and the effect again appears to disappear.

How Is A Signal Radiated? The subject of just how an *rf* signal can be propagated is a most profound one, and virtually all the first installment of our previous Advanced class study course (March, 1968, issue) was devoted to it.

A few minor modifications to the propagation model we put together in answer to our question "How Does Signal Reflection Occur?" can, however, offer some additional insight into the subject.

As we explored reflection and refraction, we discovered that a conductor cannot refract a wave but must reflect it. At that point, we declared that the energy had no place else to go and so all the incident wave went back out as a reflection.

If, however, the conductor happens to be serving as an antenna, that statement was not fully correct. The energy *does* have some place else to go – down the feedline.

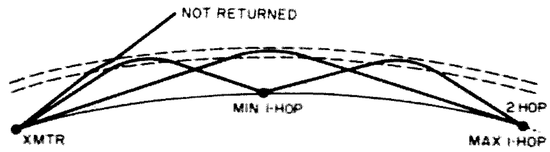

Fig. 4 – Both single and multiple-hop propagation are shown here. Wave launched at original angle for shortest skip range hits earth at moderately steep angle and is reflected back toward ionosphere. There it is refracted again and comes back down at double the original distance. "Skip distance" is distance from transmitter to the minimum 1-hop point; this region is sometimes called the "dead zone". Waves launched at higher angles fail to return (except for Pedersen waves, see Fig. 3). Those launched at intermediate angles fall between minimum and maximum 1-hop ranges.

In the case of a transmitting antenna, energy is coming up the feedline instead. In either case, the system is no longer in perfect balance.

When the frequency of the wave which is exciting the antenna is such that a standing wave can develop on the antenna structure itself, it does so. This standing wave can be thought of as the re-radiated wave from all the surface particles. However, since the standing wave maintains a perfect phase relationship with the radiated energy, it will couple with the radiation field and permit a much more efficient transfer of the energy itself.

What's more, the fields of the standing wave will induce a current *inside* the conductor – where the radiated wave itself cannot get because of reflection at the surface. This action is what moves the energy through the totally-reflecting boundary of the conductor.

If we're trying to radiate a signal rather than receive one, we begin by pumping energy into the antenna conductor at a frequency at which the antenna has electricl resonance. This produces a standing wave upon the antenna, and this standing wave is accompanied by a magnetic field which is directly associated with current flow in the conductor.

The variation in the magnetic field is accompanied by a variation in the electric field established between the ends of the antenna conductor, and the phase relationships between the magnetic and electric fields which result are such that the "wave" which they define is a travelling wave rather than a standing wave.

A travelling wave is, by definition, one which is being radiated through some medium – usually "space". A standing wave, on the other hand, is confined to a physical structure such as an antenna.

While most antennas radiate by means of a standing wave created upon their structure, this is *not* an absolute requirement. Any resonant antenna has a standing wave, and so do such "non-resonant" antenna types as the long wire.

The terminated V, the rhombic, and the Beverage antenna designs, however, all make use of travelling waves without requiring a standing wave as well.

Travelling-wave antennas are inherently less efficient in the transfer of energy for a given amount of wire; the absence of the standing wave to help couple energy from inside the conductor to the outside of it must be paid for in a much larger structure. Travelling-wave antennas are almost invariably several wavelengths long, while the most common standing-wave antenna is the half-wave dipole, and the quarter-wave whip is no rarity either.

The difference is brought about largely by the difference in current distribution in a travelling-wave antenna as compared to a standing-wave antenna. **Fig. 5A** shows the familiar standing wave of current upon a resonant antenna; **Fig. 5B** shows the current distribution on a travelling-wave antenna.

The difference is marked; in the resonant antenna, current is highest near the center and drops to virtually zero at each end, while in the travelling-wave antenna the current is essentially constant throughout the conductor, dropping only because of radiated energy.

Those portions of the conductor which carry the greatest current are simultaneously surrounded by the strongest magnetic field since the magnetic field and the current are closely associated.

As this magnetic field couples to its surroundings, each tiny portion of the antenna acts as if it were a separate source of radiation.

With the constant current in the travelling-wave antenna, all these separate sources are radiating in essentially the same phase (the only phase differences are those introduced by the physical length of the conductor) and at essentially the same strength. The result is an interference pattern which causes most of the individual fields to cancel each other out just as did the re-radiation of

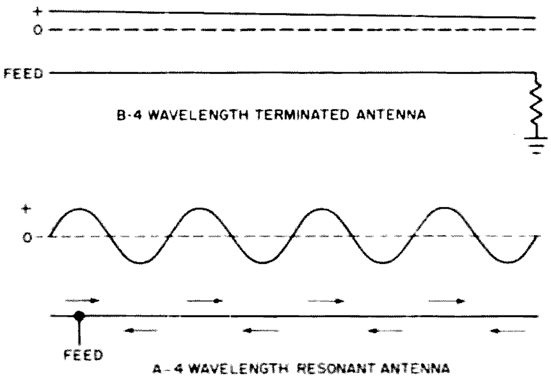

Fig. 5 — Difference in current distribution between resonant antenna (A) and terminated or travelling-wave antenna (B) creates differences in radiation patterns. On resonant antenna, current goes in different directions at different points to create standing wave. On terminated antenna, current flow is all one-way, from feedpoint to termination. Both antennas are shown as being "current-fed" at maximum current points.

individual particles in refraction. Those which add up instead of cancelling become travelling waves leaving the antenna.

In the resonant antenna, the separate portions of the conductor are not necessarily in phase with each other because the total reflection at the ends of the antenna introduces a 180° phase change, and they most certainly are not of equal strength as radiators since the current is not constant. Mutual interference still operates to cancel out most of the fields and leave a radiating travelling wave – but the pattern is different.

The most noticeable difference is that the travelling-wave antenna is unidirectional while the standing-wave antenna is not. This is because the current in the travelling-wave antenna is flowing only one way, while in the standing-wave antenna current is flowing in both directions (out and back) at the same time to create the standing wave.

Fig. 6 compares the directional patterns for a terminated long-wire antenna (a travelling-wave type) and for a resonant long-wire of the same length.

A key point to keep in mind concerning signal radiation is that each individual small part of any radiating structure, such as an antenna, radiates with equal strength in all directions. Its radiation pattern is essentially a perfect sphere.

However, any radiating conductor which has any length at all must be composed of many such small parts, and each of them is radiating in slightly different phase from all the rest since the exciting energy takes at least a little time to get from one to another, and phasing *is* time delay.

The result is that any possible (as opposed to theoretical) antenna must have some type of radiation pattern, which is the result of the interference pattern created by the individual spherical patterns of its individual parts. That's why we looked at refraction and reflection first; the exact same principle is involved in the creation of the radiation pattern for any antenna, and as we shall discover shortly is also involved in our efforts to concentrate a signal in a desired direction.

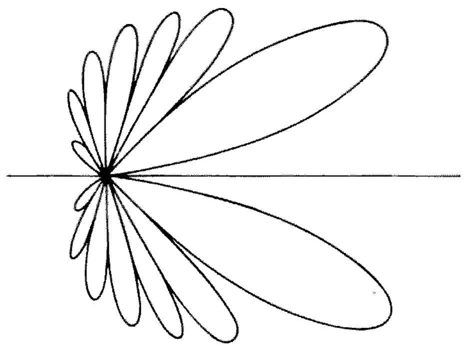

Fig. 6 — A — Radiation pattern of terminated antenna four wavelengths long is unidirectional in general direction of the wire, but has a null directly off the wire's end. The pattern's main lobes make 26° angle with wire. Pattern is symmetrical in three dimensions; consider this a cross-section view of it looking down from top.

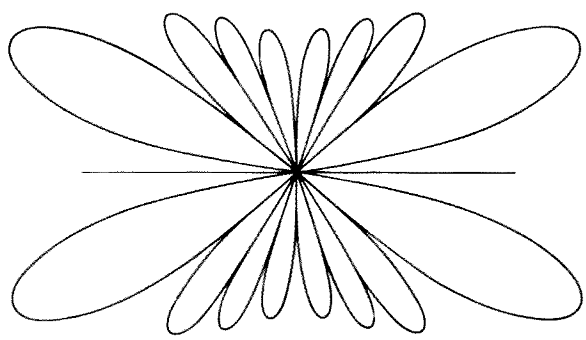

Fig. 6 — B — Resonant antenna of same 4-wavelength length has this type of pattern; it's like the terminated antenna's pattern with a mirror image superimposed on it. Result has main lobes in both directions, still with 26° angle and symmetrical shape. Bidirectional current flow (Fig. 5) is directly responsible for this bidirectional pattern.

How Can a Signal Be Concentrated? The "isotropic" antenna, which doesn't exist in practice but is the basis of antenna theory, radiates any power applied to it with equal strength in all directions. Its radiation pattern is a perfect sphere.

As we just saw, any possible physical antenna must be made up of several different atoms and so cannot be a perfect isotropic antenna – but even if we could get one, nobody would want it. *rf* power is too difficult to generate to waste by beaming as much signal straight up into space and straight back down into the ground as we send in the desired directions!

Any practical antenna performs at least some concentration of its signal, then, by putting it all into its radiation pattern. What we're really concerned with here is how we can concentrate the signal even more. It would be nice, for instance, to be able to put all our power in just the direction we wanted to transmit, without wasting any of it in undesired directions.

Such antenna designs exist, of course, and are known by the general name of "beam antennas" since their purpose is to concentrate as much of their power as possible into a single beam.

At least four major types of beam antennas have been developed, and many different designs within each type bear individual names. The types are (1) driven arrays, (2) parasitic arrays, (3) reflective systems, and (4) travelling-wave antennas.

Driven arrays include broadside arrays, endfire arrays, and combinations of the two. The Lazy H, ZL Special, 8JK beam, and Franlkin Collinear array are examples of driven arrays, as are most directive BC-station installations.

Almost all parasitic arrays are of the endfire type; the most common such design is the Yagi antenna.

Reflective systems are used primarily in the UHF and higher-frequency regions, and include the "big dishes" and the corner reflector.

Travelling-wave antennas include the terminated V, the rhombic, and their variations; these are most usually used only at low frequencies where the other types of beams are not practical. One type of travelling-wave antenna in wide commercial use at high frequencies is the helical beam.

Any single beam antenna installation may mix or match these types. Especially popular among VHF workers is a combination of driven and parasitic arrays in which several separate parasitic arrays are driven at the same time to form a driven array of parasitic arrays. Fig. 7 shows the idea. At UHF, a

corner reflector is sometimes incorporated into a parasitic array to increase the beam concentration and reduce unwanted back-lobes.

Since most beam antennas in ham use are either driven arrays, parasitic arrays, or combinations of the two types such as that shown in **Fig. 7**, we'll concentrate on only these two types for now.

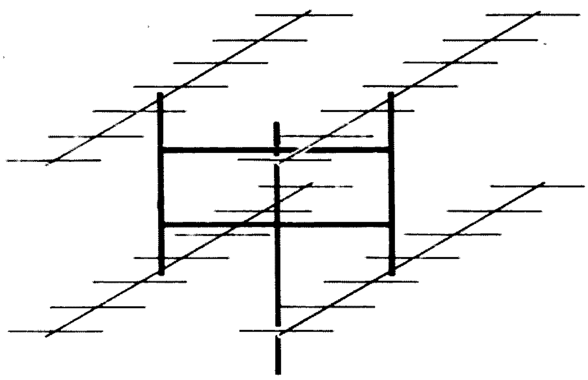

Fig. 7 – Quad Yagi antenna installation popular with serious VHF enthusiasts is typical example of an array of arrays. Each of the four Yagis is itself a parasitic array, and the four are arranged and fed as a two-by-two broadside driven array. Result is highly directional pattern and maximum gain; as much as 18 db power gain can be achieved in practical amount of space with careful design and adjustment.

The driven array consists of a number of individual antennas arranged in some regular pattern, all of which are driven at the same time from the same source. It's exactly the same principle as the radiation from separate atoms in refraction, except that it's at a much larger scale.

Fig. 8 shows the essential portions of any driven array; each individual antenna is shown here only as a dot rather than as a wire, because it's easiest to see what's happening if we think of each individual antenna as an "isotropic" one for the moment.

If each of the individual antennas is fed with current of exactly the same phase, then the array is a "broadside array" because it will concentrate the pattern to be strongest in the directions broadside to the line of the antennas. That is, the pattern shown in solid lines will result.

This is caused by interference between the patterns of the individual antennas. Only at point P (and other points along the line between P and the center of the array) will a receiver get equal amounts of in-phase energy from all the individual radiators. At other angles, the waves from one antenna must travel further (and so take longer en route) than those from another, and so will arrive out of phase. This causes a partial cancellation. The pattern is the result of all these partial cancellation effects.

If, however, the antennas are fed differently, the pattern will change. For instance, if the feedline is connected directly to the leftmost antenna and goes to the adjacent one through an additional length of cable which introduces a phase delay, and so forth down the line, and if that phase delay is chosen just right so that the energy *feeding* each array is in phase with the energy arriving from its neighbor to the left, then the only point at which all antennas contribute equally is that marked Q. The resulting radiation pattern is shown in dotted lines in **Fig. 8**, and the array is now an "endfire

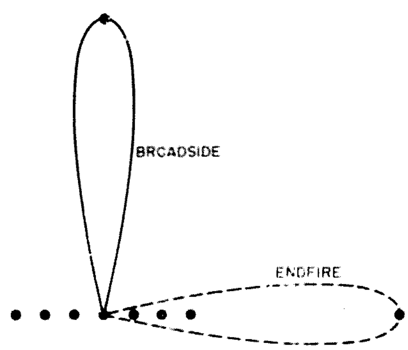

Fig. 8 – Basic patterns of driven arrays are broadside and endfire as shown here. For simplicity, each element of this array is shown as an isotropic (point-source) radiator and all minor lobes have been omitted. Both patterns repeat themselves in opposite direction; that is, they are bidirectional. Difference in direction between broadside and endfire patterns is due to feedline phasing within array; main lobes can be tilted to any in-between angle by proper phasing but this is not usually done with ham antennas.

array" since it fires its strongest beam off the end of the line of antennas. The only change necessary to obtain this 90-degree change in direction was to change the phasing of the feedlines.

By appropriate choice of phase relationships between the various antennas in a driven array, the beam can be tilted to any point between the broadside position and the endfire pattern. This is done in BC-station design, but in ham work it's much easier to simply rotate the array.

If, instead of the imaginary isotropic antennas we used in **Fig. 8**, the individual elements of the array are dipoles (as they

usually are) then the radiation pattern of the dipole gets into the act. Broadside arrays made up of dipoles are usually set up either parallel to each other, or end to end, as in the "colinear" antenna. Endfire arrays of dipoles on the other hand usually have the antenna conductors arranged at right angles to the line of radiation, like the Yagi parasitic array (which has an endfire radiation pattern).

A parasitic array is essentially a driven array in which only one of the antennas is actually driven, and the rest pick up their energy by radiation from that one. Most parasitic arrays are endfire designs, since it's simple to get the necessary coupling and phase relationships from parallel dipoles.

The phase of the energy actually radiated from an antenna depends, in part, upon the relationship of the exciting energy's frequency to the frequency at which the antenna is self-resonant. The phasing adjustment which, in the endfire driven array, was made by adjusting feedline length, is made in a parasitic array by tuning the parastic (non-driven) elements to frequencies slightly different from that at which the antenna is to operate.

If an element is tuned to a frequency slightly lower than that at which operation is desired, the phase of its reflected or re-radiated energy will be such as to cut down the radiation pattern in its direction, and build it up in the opposite direction. Such an element is called a "reflector".

If an element is tuned to a frequency slightly higher than that at which the beam is to operate, it will build up the radiation pattern in its direction and cut it down in the opposite direction. Such an element, since it directs the pattern in its own direction, is called a "director".

The spacing between the driven element and the parasitic elements is just as critical, in a parasitic array, as is the tuning of the parasitic elements, since the array's performance is determined, by relative phase over the entiré structure. Distance determines phasing also. For any specific tuning of a parasitic element, there is a critical distance as well.

Before the principles of the parasitic array were understood as well as they now are, this led to many conflicting rules for design of parasitic beams and their tuning. About 10 years ago, however, it was discovered that the critical factor actually is the combination of tuning and spacing. It is now

known that almost any spacing (within reason) can be used, or alternatively almost any tuning of element lengths. Once a spacing is chosen, then the tuning of the elements must be matched to it; if element tuning is chosen first, then the spacing must be adjusted to obtain maximum performance.

In comparison to the other three types of beam antennas, parasitic arrays offer the highest performance per unit size. On paper at least, you can get any desired gain from a physically small parasitic array if you just use enough elements and tune and space them properly. In practice, the gain really is limited – but you can get a 10-time increase in effective radiated power from an antenna only a half wavelength wide and a wavelength long, which is much more than any of the other types of beam can provide. For this reason many engineers call such designs "super-gain" antennas.

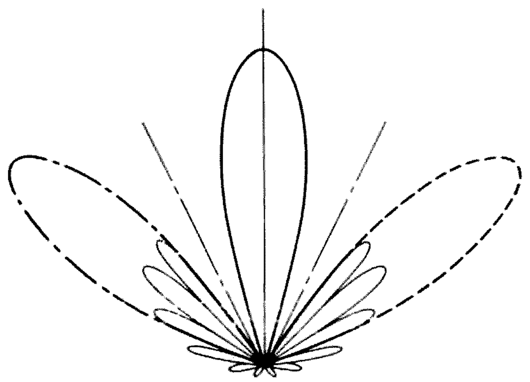

Fig. 9 – Buildup of radiation pattern for terminated V antenna with each leg 4 wavelengths long is shown. Each leg of V by itself has pattern of terminated long-wire (Fig. 6); legs are placed at proper angle to make main lobes coincide in one direction, and cancel out to at least some degree in all others.

The travelling-wave antenna, such as the rhombic or the terminated V, gets its gain by a cancellation effect also. As **Fig. 6** showed, a travelling-wave antenna is inherently unidirectional – but puts its power into a cone rather than a beam. If two such antennas are erected side by side to form a V as shown in **Fig. 9**, their patterns can be made to cancel each other out in most directions while they add together in just one and form a single beam of radiation. This is the terminated V. If the terminations at the wide end of the V are removed and another pair of antennas is put in their place, with terminations at the narrow end **(Fig. 10)**, you have the rhombic. Gain of such an antenna is moderately high,

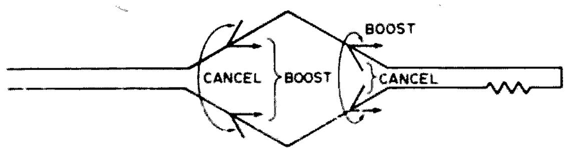

Fig. 10 – Simplified buildup of pattern for rhombic antenna is similar to that for terminated V; lobes aimed in same direction boost each other and all the rest cancel. Cancellation is more complete in rhombic.

but is nowhere near that to be expected from either a driven array or a parasitic of similar size – because each leg of the rhombic needs to be at least four wavelengths long to get the directive effect.

You can also get some directivity from an *un*terminated V. This is essentially two long-wires side by side. The cancellation effect still works to take out part of each long-wire's pattern, but the resulting beam is bidirectional with its major lobe splitting the V angle as shown in **Fig. 11**.

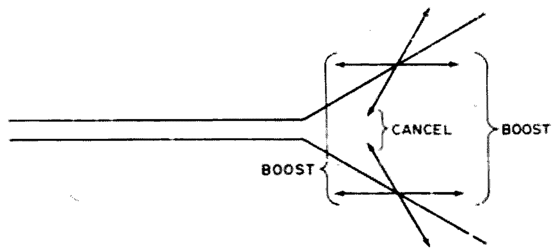

Fig. 11 – In unterminated V antenna, lobes in both directions boost each other but side lobes cancel out. Result is bidirectional beam, similar to that of broadside or endfire pattern from driven array.

The resulting pattern is similar to that you get from a simple driven array **(Fig. 8)**. A parasitic array, on the other hand, concentrates its power essentially in a single direction, as does the terminated V or the rhombic.

The subject of antennas and how they work is one of the most important in ham radio, because nowhere else can you get such an improvement in your station's performance for a comparable amount of effort. We'll be going into it more in our next few installments, but even then we will not be able to cover it completely – the subject is just too large.

A number of books are available at various levels of technical knowledge. The traditional authority on the subject is "Antennas", by John Kraus, W8JK, inventor of the 8JK beam, the corner reflector, and the helical beam. Terman's "Electronic and

Radio Engineering" contains much valuable data at a slightly less exotic level, being intended as an undergraduate text for engineering students at the college junior/senior level. "Fields and Waves in Modern Radio" by Ramo and Whinnery handles the basic principles of radiation excellently but requires at least an acquaintance with higher math (matrix algebra and partial differential equations) to read comfortably. Jasik's "Antenna Engineering Handbook" is intended for the antenna design engineer but avoids much of the deeper theory and concentrates on practical applications instead. Any or all of these are recommended for additional study, if you're really interested in adding to your knowledge of how and why antennas work as they do.

Next Month. We'll continue examining antennas, looking at such factors as harmonic rejection and feedline matching.

RENEWAL CODE

The two numbers under your call on the address label are the expiration code. We have tried to make it simple. The first number is the month that we send you the last copy on your subscription and the second number is the year. 78 would be July 1968, for example.

Loosen Those Army Set Screws!

One of the big problems faced by every would be user of the Command Transmitters is the frustrating task of loosening those special set screws on the knobs and shafts of this series. Usually one ends by using brute force and damaging the part, or just laying the equipment aside.

One of the regular screwdriver blades in the SC-5 Screwdriver set which can be purchased from the radio houses, or any good screwdriver with a very small blade will just fit into this set screw and with a stout twist will loosen any of them very quickly. If this screwdriver set is not available, grind any stout screwdriver down to about 1/16th of an inch, and they will fit into these set screws cross-wise.

The knobs and shafts of this Command series suddenly become very valuable.

NEW BOOKS

Electronics for Technicians

Written by Abraham Marcus and published by Prentice-Hall, Electronics for Technicians is a sequel to Electricity for Technicians. It describes electronic phenomena in physical terms, rather than mathematical and is extremely well-written.

The book is divided into three sections. Section I deals with the electron tube. The various types of tubes are discussed in language which almost anyone with any electronic knowledge can easily understand. Section II discusses semiconductor theory and the various types of semiconductors are examined. Section III deals with how tubes and semiconductors are used in various circuits including power supplies, amplifiers, oscillators and various circuits used in the home, in industry and communications. Mr. Marcus gives an overall view of the subject and his book should serve as a basic foundation for further study in electronics.

The book is divided into 20 chapters within the three categories, and each chapter is followed by a series of questions for the student to test his comprehension of the material. Following the 20 chapters is a series of apendices showing pin identification for electron tubes, lead identification for various transistors, and a complete section on electronic symbols which is the most up-to-date I have seen so far.

In an attractive cloth-bound cover, Electronics for Technicians sells for $9.95 and certainly contains all the study material needed for anyone interested in learning basic theory.

RCA Manuals

The RCA *Solid-State Hobby Circuits Manual* contains complete construction information on 35 circuits of general interest to experimenters. Power supplies, oscillators, keyers, preamplifiers, amplifiers, and numerous other items are covered in detail. This manual also contains sections on theory and practical application of most solid state devices, and gives information on construction practices and trouble-shooting.

The revised and expanded RCA *Receiving Tube Manual* contains up-to-date information on tube types and technology; detailed descriptive data and application information for the complete line of home-entertainment types of receiving tubes for TV and Hi-Fi enthusiasts.

Seven other technical manuals are available from RCA. *RCA Transistor Manual* is a 544 page book containing text, data, and typical circuits for the complete line of transistors, silicon rectifiers, and other semiconductor diodes.

RCA Silicon Power Circuits Manual is a 416 page book providing design information for a broad range of power circuits using silicon transistors, rectifiers, and thyristors.

RCA Linear Integrated Circuits (352 pgs.) contains basic principles of design and application information for linear integrated circuits.

RCA Silicon Controlled Rectifier Experimenter's Manual is a 136 page book containing 24 interesting control circuits using semiconductor devices available in kit form.

RCA Transmitting Tubes is a 320 page book giving data on more than 180 RCA power tubes with plate input ratings up to 4 KW.

RCA Phototubes and Photocells (192 pgs.) contains design information and data for 90 photosensitive devices.

RCA Tunnel Diodes is a 160 page book containing information for RCA tunnel diodes for switching and microwave applications.

Prices range from $ .65 to $5.75. For a complete brochure and prices write Commercial Engineering, RCA Electronics Components, Harrison, N.J. 07029.

Motorola Semiconductor Handbook

The Semiconductor Power Circuits Handbook contains the latest information in power circuit design. Some 150 new circuits have been specifically designed for users of power transistors, thyristors, rectifiers and zener diodes. This 264 page manual includes many designs being published for the first time. It is divided into six chapters devoted to motor speed controls, inverters and converters, regulators, statis switches, audio and servo amplifiers, and miscellaneous thyristor switch ap-

plications. Copies may be obtained by sending $2 to Motorola Inc., Box 20924, Phoenix, Arizona 85036.

Hayden Books

This one is a beauty. The *Transistor and Diode Laboratory Course*, by Harry E. Stockman, clearly illustrates and develops the concept of transistor theory. This 117 page book is designed either for the classroom or for home study. The first half of the book is devoted to theory, providing a background in transistor technology. The remainder is experiments dealing with intricate transistor networks. Each chapter is followed by a question and answer session. For anyone who wants a more sophisticated approach to transistor theory and application, this book is a must. Available for $3.95 from Hayden Book Company, Inc., 116 West 14 Street, N. Y., N. Y. 10011.

Economy Chronometer

How would you like to have an illuminated station clock for less than $5.00?

The unit described was built at a total cost of $3.14 plus tax, but, with a well-stocked junk box, this figure could be reduced still further.

The secret of such a bargain lies in the fact that most "electric" automobile clocks are really mechanical clocks which are wound electrically every two to five minutes. Since this winding is done by a pulse through an electro magnet, the clock doesn't care whether this pulse is ac or dc, thus making it a simple matter to power the clock in the home station.

These clocks are available from your local salvage yard, and sell for 50 cents to $3.00, depending on the condition and whether or not *you* remove it from the wreck.

The major enemies of auto clocks are moisture and dust. The latter is the most common but least damaging. In selecting a clock, pick one which shows no sign of rust on the face, hands, or any other exposed surface, and your chances of restoring it to service are almost a certainty.

To remove the clock from the case pry up the edges of the bezel which holds the glass and remove these parts. Two or three small screws or nuts in the back of the case will now allow the clock to be removed.

A large eye dropper or "ear" syringe will supply a low velocity air blast for cleaning. Do not attempt to use a brush, as fragments of the bristles will catch in the gears.

The most common cause of failure is in the winding mechanism, so a complete description of this operation is in order. On the back of the "works" is a rather large winding surrounded by a rotary armature. When this armature is aligned with the winding, the clock is wound. As the clock runs down, the armature moves away from the poles of the winding, and, near the end of its travel, a pin on the armature engages a Y-shaped yoke and closes a pair of contacts. These contacts are in series with the winding and the voltage source, so when they close, the winding is energized and the armature is drawn toward the poles of the winding. This rewinds the clock. This movement of the armature also opens the contacts by the action of the pin in the yoke. This contact between pin and yoke is where trouble develops. Just before the contacts close, the mechanism is at a point of maximum friction and minimum spring tension; so, with the collection of dust and evaporation of lubrication, the clock stops just short of rewinding.

After all traces of dust have been removed, apply a *drop* of solvent/lubricant of the type used for tuners and volume controls (Quietrol, Spra Kleen, etc.) to the yoke where it contacts the pin. Wind the clock by pushing the armature, and start it by lightly pushing the balance wheel. It will probably stop just before the contacts close. Without rewinding, start it again and let it run until the contacts do close. Rewind and repeat until it runs freely from rewind to point closure. Dry the yoke and apply a minute quantity of lubriplate (a very light lubricant cream available from hobby and gun shops) to the point of contact with the pin. If desired a small amount of the solvent/lubricant can be applied to the pivots and teeth of each gear. The smallest drop you can get is slightly too much for each point, so if you wish to skip this, the clock will probably run without it for years.

The points may be cleaned with a burnishing tool, but avoid excessive filing.

While the clock is "running in" the power supply can be prepared. The transformer can be any, which gives the proper voltage. My clock used 12 volts, so a 6.3 and 5 volt winding were connected in series to give 11.3 volts. This is plenty, since the winding is designed to work on 10-14 volts. The transformer also has a 90V winding which is not used, so the leads are taped to prevent shorts and left hanging free.

To determine the required voltage, look at the bulb in the socket which sits inside the case. If the bulb is missing, apply 6.3 ac between the input terminal and frame, and observe the armature. If it moves toward the poles of the winding (not necessarily all the

way) use 6.3. If the winding buzzes and the armature doesn't move, the higher voltage will be required.

When the proper voltage is found, let the clock run until it rewinds a few times to make sure all is well, then re-install it in the case. Most of these clocks have a cable clamp on the back which will make a convenient point for the ground connection, or a self-threading screw can be installed in a spot where it will not hit the works.

These clocks come in a variety of sizes and shapes, and take naturally to panel mounting, or a small chassis or Mini-box can be used as a case. A switch may be installed to turn off the light, if desired, but the location of the bulb is such that it illuminates the clock face and little else, so it is left on in my installation.

The transformer can be mounted in the case with the clock, or up to 10 15 feet away, depending on your needs. Lamp cord is fine for this connection.

This will not bring National Bureau of Standards or even IBM into the shack, but it is a reasonably accurate timepiece, and the price is right.

4 x 150 Sockets

Larry Jack, WA3AQS
7421 Gwynndale Drive
Clinton, Maryland 20735

It was about a week after completing the small sideband rig that I realized its single watt wasn't going to be enough. After a few, "You're readable, but kind'a weak" signal reports, I returned to the junk box, this time for parts to build a linear. From among the assorted trivia were unearthed a handful of 4x150's. Two hundred watts output at least–a very good tube for the new amplifier–but I didn't have any sockets for them. Being a little impatient to get started, and adventurous at heart, I elected to build the sockets rather than wait out an order from a supply house.

A simple modification of a regular octal socket provided a new base. A ceramic type (for its low losses) was selected. Then all the metal pins were carefully removed from the collar. The pins are crimped to make firm connections with the new size pins of the 4x150, and then are replaced back into the socket.

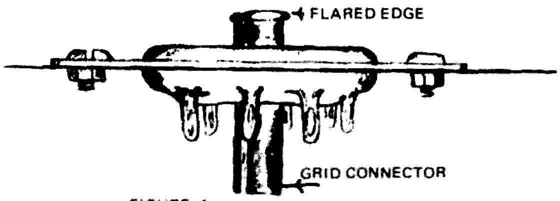

FIGURE 1

A grid connector was made by flaring the top of a semi-circle of sheet metal about 1½ inches high *(Fig. 1).* This connector was placed into the socket key so that the gap between the semi-circle lines up with the slot in the key of the base. To prevent the connector from slipping out again, solder was melted about it, on the underside of the new tube base *(Fig. 2).* For cooling, the tubes were placed almost directly in the mouth of a large squirrel cage blower.

I originally had used only a single .01 μF capacitor soldered directly at the socket pin as the screen by-pass. The rig took off, so to speak, in a very unstable fashion, so small straps on a standoff insulator with another .01 μF capacitor was put above the chassis to by-pass the tube's screen ring. This cured the trouble *(Fig. 2).*

Cooling never figured as a problem. At 50 MHz with inputs reaching 600 watts, a single 200 cfm blower has kept a pair of one-fifties running cucumber cool. Not so many "kind'a weak" reports now.

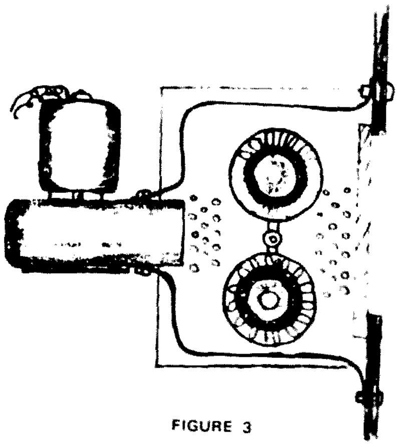

FIGURE 3

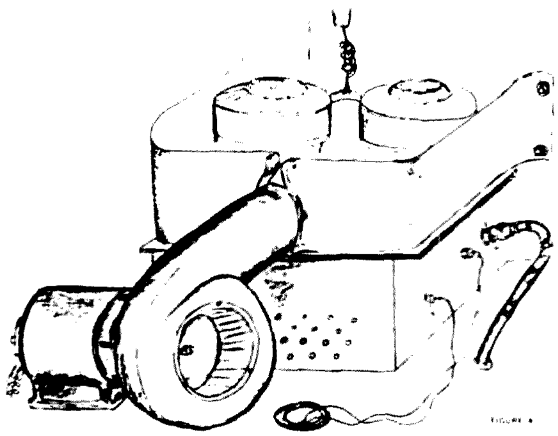

RF Sealing Tape

RF sealing is one of the strategies employed in building transmitters that do not generate TVI. The unwanted *rf* is generated but the enclosure is designed so it never gets out.

The same approach is used to build receivers that do not respond to any *rf* except that which enters the receiver through a coax connector, and in the construction of laboratory signal generators.

But did you ever try to convert a non-shielded enclosure into a shielded enclosure? It can be done, but ;ften it is a task to make strong men weep. Hinges, joints, ventilation, doors, meters, . . . and how about shielding some of the wiring that carries power through areas hot at *rf*?

Scotch Rescue

The 3M Company has developed a remarkable copper foil tape with an electrically conductive pressure sensitive adhesive. The tape adheres directly to clean metal with a good low resistance electrical connection between metal and copper foil. The tape can improve leaky shielding by up to 60 dB. It is designated "Scotch" Brand Electrical Tape No. X-1181 and comes in 54 foot rolls of assorted widths.

The tape is used alone, or with perforated or solid aluminum sheet. The sheet is available in most hardware stores. It is cut into sections, shaped to fit, and taped in place. Large shielding assemblies can be made up from smaller ones. You must wash the aluminum with detergent to get any oils off before taping.

One approach to reducing *rf* pickup by power or control wiring in transmitters is to use shielded wire. This is horrid stuff to work with, if you have ever tried it. A piece of ordinary hookup wire can be laid along the chassis and covered with a strip of shield tape, to achieve the same result.

An All Band Curtain Array

1.75 to 30 MHz

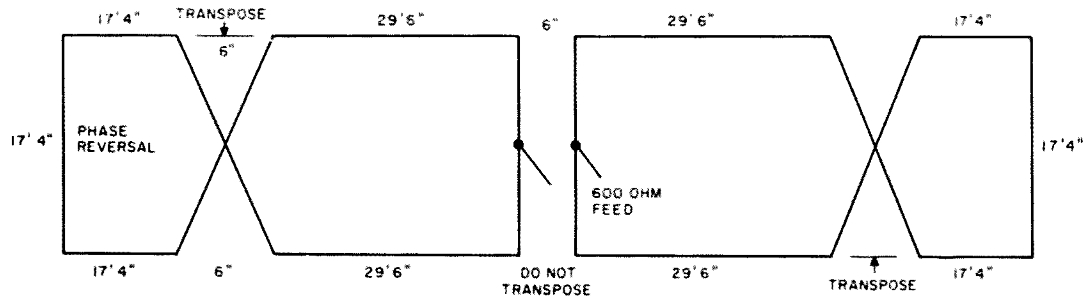

Fig. 1. Dimensions for the all band curtain array.

Looking for something better than a random length flat top for your multi-band operation? This pint sized array which puts out a big signal should more than provide the answer. After some cut and try trials, the configuration shown in **Fig. 1** was decided upon as the best all band result. It represents an attempt to get the *most* with the least outlay. All that is required over a flattop is some extra wire and insulators. It should be easily erected on any average lot, as the total length between poles is approximately 112 feet. It has superior gain over most flat-tops on 14, 21, and 28 MHz. Its low angle of radiation being one feature. If it is not possible to erect it to its full length, the 8 foot spacing at the transposed sections can be reduced somewhat with slightly less gain available.

On 1.75, and 7 MHz respectively, it really performs as a quarter, half, and 2 half waves in phase. However, the configuration at 7 MHz does add some gain and lower the angle of radiation slightly. If DX is desired on these bands, the bottom wire must be at least 30 feet above ground and preferably much more. For DX on 14 through 28 MHz the bottom wire should be a minimum of 20 feet above earth. On 28 MHz, there are some 8 wavelengths of wire up in space which adds to the signal.

Maximum radiation is mainly broadside on bands 1.75 through 21 MHz. It throws the sharpest beam with the most gain on the latter band, while on 14 MHz, the pattern is broad and something in shape like a three leaf clover on either side of the axis. No db measurements have been attempted, but its performance is far superior to a random length wire used at the same QTH and strung at a comparable height. Since it is horizontally polarized, the higher the array is strung up, the better.

Being multi-band, no attempt can be made to match the 600 ohm feedline, which can be any length, but may have to be pruned if the array is reticent to accept power on any one band. A flexible all band antenna tuner is a must for proper loading.

How To Tune A Circuit

In these days of intricate and relatively inexpensive commercial radio equipment, home building of ham gear is not so common as it used to be. However, a great deal of pleasure and satisfaction may still be had from the designing and building of simple receivers, converters, etc., even if you never intend to actually use them on the air.

One fairly critical part of most simple projects is the tuning circuit. At frequencies through the VHF region, a tuning circuit usually consists of an inductor (coil) and a variable capacitor, which is adjustable over a reasonably wide range. It is easy to find, by the trial and error method, some combination of inductance and capacitance that will tune to the desired frequency. The trouble usually begins when you try to band-spread the circuit; that is, to make the entire tuning range of the variable capacitor cover only the desired frequency range. This frequency range may be only several hundred kilohertz wide, such as an amateur band or a shortwave broadcast band.

This article will attempt to illustrate the problems involved, and how to solve them by the use of a grid-dip oscillator and some simple charts and formulas. First, however, a few words about circuit theory may be in order.

An inductor or a capacitor will oppose the flow of an alternating current. This property is called reactance, and differs from resistance in that the current through the reactance is 90 degrees (or one-quarter cycle) out of phase with the voltage. In an inductor the current lags the voltage by 90 degrees, and in a capacitor the current leads the voltage by 90 degrees. The amount of reactance is determined by the value of inductance or capacitance, and by the frequency of the alternating current. Inductive reactance increases with an increase in frequency, while capacitive reactance decreases with an increase in frequency.

When an inductor and a capacitor are connected, either in series or parallel, there will be one frequency at which their reactances are equal. Since the inductive reactance causes a current lag of 90 degrees, and the capacitive reactance causes a current lead

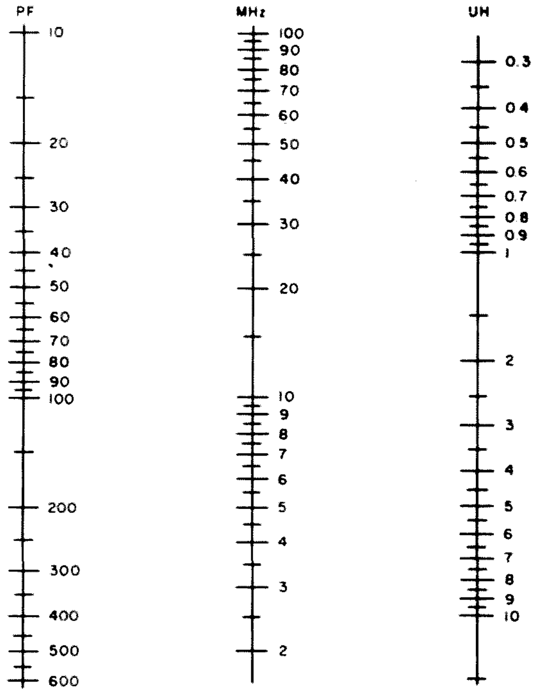

Fig. 1. Resonant frequency chart. By laying a straight edge across two known quantities, the third can be determined.

of 90 degrees, the reactances cancel each other, and the circuit is said to be in resonance. The series resonant circuit offers a very low resistance to the flow of alternating current at the resonant frequency, and the parallel resonant circuit offers a very high resistance to the flow of alternating current at the resonant frequency.

The frequency of resonance may be found by using the formula: $f = \frac{1}{2\pi\sqrt{lc}}$ with f in Hertz, L in Henrys, and C in Farads. A simpler method is to use a chart like the one in Fig. 1. By laying a straight edge across two known values, the other quantity may easily be found. Charts covering a wide frequency range may be found in Allied's Electronic Data Handbook and other similar publications. There is also a chart on page 70 of the August 1967 issue of 73 Magazine.

Let us say that you wish to build a circuit that tunes from 7.0 MHz to 7.3 MHz. You have a variable capacitor from the junk box that you wish to use, a few surplus coils with unknown inductance values, and an assortment of small fixed capacitors. You also must have a calibrated grid-dip oscillator.

In order to find the capacitance of the variable capacitor, you will first need a known value of inductance. Pick a likely-looking coil from the junk box, or wind one by guess or by using a coil winding chart. The chart found in Allied's Electronic Data

Handbook is easy to use and accurate for coil diameters from ½ inch to 5 inches. Connect a fixed capacitor with a known (marked) value across the coil and find the resonant frequency of the combination with the grid-dip oscillator. If possible, use a mica capacitor with a 5% or 10% tolerance. Let's say you use a 100 pF capacitor and the resonant frequency is 9.2 MHz. By laying a straight edge across these two values on a resonance chart (**Fig. 1**), the inductance of the coil is found to be 3 uH.

The 3 uH coil may now be used to measure the minimum and maximum capacity of the variable capacitor. Connect the coil across the variable capacitor and measure the resonant frequency at the minimum and maximum capacitance settings. If the resonant frequency is 20 MHz at the minimum setting and 5 MHz at the maximum setting, the variable capacitor has a range of about 22 pF to 350 pF.

You will note that the frequency ratio (4 to 1) is equal to the square-root of the capacity ratio (16 to 1). This is important to remember, and is true also for the inductance ratio when the capacity is held constant. Thus, in the circuit above, if it were desired to bring the lowest frequency down from 5 MHz to 2.5 MHz, a 2 to 1 frequency ratio, the capacity or inductance would have to be increased by 2 squared, or 4 times (1400 pF with 3 uH, or 12 uH with 350 pF).

Now that the variable capacitor has been measured, a coil can be chosen that will tune the desired 7.0 to 7.3 MHz range. It may be seen, by checking our resonance chart, that the 3 uH coil used in measuring the variable capacitor will tune to 7.0 MHz with about 175 pF, and to 7.3 MHz with about 160 pF. As this is well within the range of our variable capacitor, we may as well use it in our circuit.

Band-Spreading

Although our circuit will tune through the range of 7.0 to 7.3 MHz, the required capacity change of 15 pF would be covered in only a small fraction of a turn of the capacitor, and tuning would be very difficult. This problem is easy to solve, however, by the addition of two more capacitors to the circuit. Since we need a variable capacitor with a range of 160 pF to 175 pF, a capacitor may be added in series with the variable to lower the total maximum capacitance from 350 pF to 175 pF, and a capacitor may be added in parallel with these two to raise the minimum capacitance from 22 pF to 160 pF. See Fig. 2. The series capacitor is called a padder and the parallel capacitor is called a trimmer.

The value of the trimmer should be determined first. Its approximate value can be found by subtracting the minimum capacitance of the variable from the desired minimum capacitance. Thus 160 pF minus 22 pF equals 138 pF for the trimmer. The value of the series combination of the variable at maximum capacitance and the padder is equal to the total desired maximum capacitance minus the trimmer capacitance. Therefore 175 pF minus 138 pF equals 37 pF for the combination of the variable (set at 350 pF) and the padder. The value of the padder may be found by the formula: Cl=CtC2/C2-Ct, where CI is the padder, C2 is the variable, and Ct is the desired total. This works out to 41 pF for the padder.

Since the padder is only about twice the value of the minimum capacitance of the variable, it will have a noticeable affect on the total minimum capacitance, making it 152 pF instead of the desired 160 pF. This difference will be more than made up for, however, when other parts of the circuit are connected to the tuned circuit. Stray circuit capacitance and the input or output capacitance of the tube or transistor used will add from 5 to 10 pF or more to the total capacitance. At the higher frequencies this becomes increasingly important, and should be allowed for.

When building a circuit one stage at a time, remember that when the following stage is connected it will upset the output tuning of the previous stage. It may be helpful to connect a small value of capacitance temporarily across a tuned circuit that will later be connected to another stage. When the other stage is connected you can remove the capacitor. At high frequencies, where the adjustment range may be small, this may keep you from having to rewind the coil.

A good type of capacitor to use for trimmers and padders is the adjustable mica

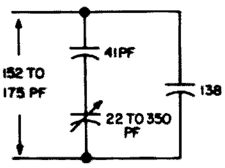

Fig. 2. The 22 to 350 pf variable capacitor is effectively changed to 152 to 175 pf by the addition of two extra capacitors.

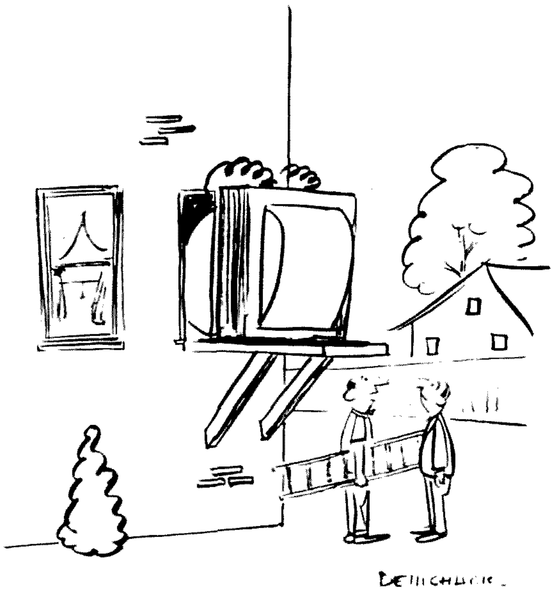


"I added a linear."

compression type. These are small and inexpensive, and come in sizes ranging from about 1 pF to over 3000 pF. The minimum to maximum capacitance ratios vary from about 10 to 1 in the small sizes to about 2 to 1 in the largest sizes. When using adjustable capacitors set the high frequency limit with the trimmer, and the low frequency limit with the padder. Since the adjustments affect one another they may have to be repeated several times. If maximum stability is important, fixed silver mica or adjustable air capacitors should be used.

I have not mentioned circuit Q. This quantity is important in the output circuit of transmitters, in circuits where maximum selectivity is important, and many other places. However, in most simple low-power circuits the Q may be safely ignored.

. . . K5LLI

SSB Escalator – Part II

Since the original article on *rf* SSB speech clipping appeared in 73 Magazine (p. 16, Dec., '66), I have received a number of inquiries relative to the construction of the clipper unit.

Resistors R3 and R4 in *Fig. 1* should be interchanged (this was a printer's error). Replace the 300Ω cathode resistor of V2 with one of 68Ω and the 47k screen resistor with one of 20k. At the grid input of V1 the 22k resistor is omitted and a 140 pF APC variable capacitor is substituted for the fixed 180 pF condenser for maximum tuning of the signal. Mount the mechanical filter topside with its midpoint baffle shield omitted—an original but later-proved unnecessary precaution.

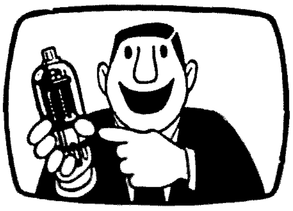
It is important that the filter employed be identical to the one in the exciter unit. If the carrier frequency is not down on the filter skirt at or very close to that in the exciter unit, one of two undesirable things will take place: either the lower voice frequencies will be out of range of the passband and the audio will sound tinny, or insufficient sideband rejection of the lower clipped voice frequencies will occur with unwanted, newly generated frequencies. It may be preferable to extract the *rf* signal at the output of the balanced modulator rather than at the output of the following *if* stage. In place of the original Millen *if* transformer, T1, try a less expensive one; T2 may be a Miller 912-C4 *if* transformer. The .01 mfd coupling condenser in the secondary lead of T2 may be left out.

The power supply can be placed on the same chassis with the clipper unit although a larger chassis, of course, will be required. Any power supply system that will deliver from 30 to 50 mA at a regulated voltage of 105 to 150V will be satisfactory.

The following simplifications may be made: Omit the sub-miniature switch, S1, and run the two RG-174/U coax input and output leads directly to the two jacks mentioned in the paper. A short coax-cabled jumper between the two jacks will restore the original exciter operation. Omit both the no-clip gain control and the DPDT switch, S2. Simply rely on the clip level control to adjust the amount of *rf* clipping.

If excessive hum is encountered when clipping, it may, unfortunately, be necessary to shield the exciter's audio input stage.

Louis Berman, K6BW



NEW PRODUCTS

HEATHKIT
2 Meter Transceiver
Model HW-17

Heath 2 Meter Transceiver

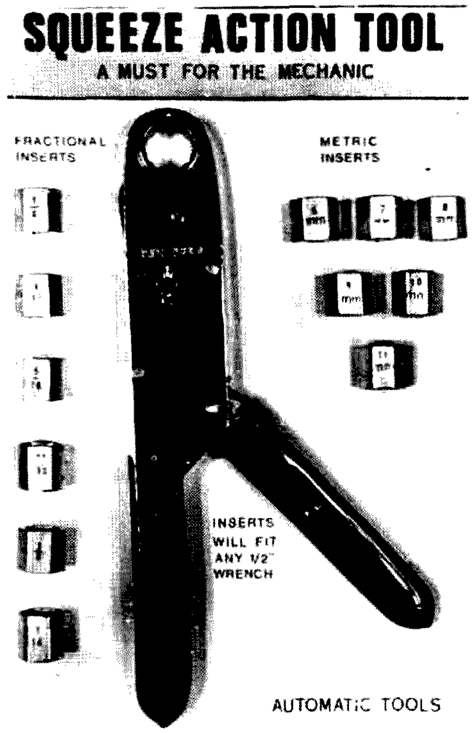
The latest in a growing line of "single banders" has come out of the Heath Company. This new unit, the model HW-17, covers the amateur two meter band and also has facilities for the MARS and CAP frequencies. Crystal controlled, the output is about 10 watts AM.

The dual-conversion solid state receiver has 1 microvolt sensitivity and features a prealigned FET tuner, ANL, Squelch, "Spot" function, lighted dial and a relative power output meter. It comes with a built-in AC power supply and microphone. The DC supply for mobile operation is optional at $24.95. Priced at $129.95, this is a best buy item. For further information, write Heath Company, Benton Harbor, Michigan 49022.

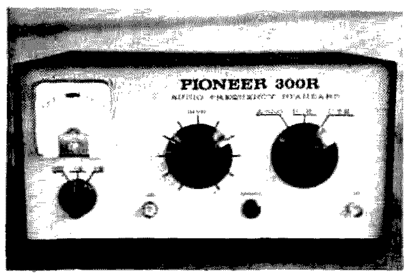
SQUEEZE ACTION RATCHET WRENCH

Fulfills the requirements of professional and home mechanics. In hard to reach areas, turning is accomplished by merely squeezing spring loaded scissor type handle. Where there is more room it can be operated like a conventional ratcheting box wrench. For reverse action, just turn the tool over. Box socket is ½". Twelve hex inserts range from ¼" thru 9/16" and millimeters from 6 mm thru 11 mm. A rubber friction lock keeps the insert firmly in position. Retail $12.95.

For further information contact THE JAY THOMAS COMPANY, 117 West Oxford Street, Dept. M.M.-5, Chula Vista, California 92011.



Pioneer 300R Audio Frequency Standard



The Pioneer 300R is a highly stable seconcary frequency standard of completely solid state design, using quartz resonators for stability. It functions as a tone receiver or tone transmitter. The stability is .005% and switching allows selection of up to three standard frequencies. It provides a built-in attenuator for receive applications.

It can be used in the receive mode for calibrating oscillators directly without the use of an oscilloscope or other indicating device normally needed with a standard to indicate zero beat. It is an indispensable piece of equipment for RTTY, and a valuable calibrator for oscillators, oscilloscopes, and bridges. Accurate inductance and capacitance measurements can be made using this precision source. To guarantee stability over a wide range of temperatures, the resonators are kept at a nearly constant temperature in an insulated and shielded oven. The oven comes as a sealed unit with desired resonators included

inside. Additional frequencies may be obtained for $35 each.

For further information write Pioneer Electronics, 738 Pacific St., San Luis Obispo, California 93401.

Linear Systems, Inc.

David C. Thompson, President of Linear Systems, Inc., has announced the election of David K. Bradley as Vice President, Marketing for the firm. Mr. Bradley previously was National Sales Manager for the SBE line of amateur radio products at Raytheon Company, South San Francisco, California. He has been active on several EIA committees in the amateur and citizens band business. Mr. Bradley is well known in the amateur radio fraternity and has the amateur license W6CUB. Prior to joining Raytheon, Mr. Bradley owned and operated an amateur radio distributorship in Northern California. Mr. Thompson stated that Mr. Bradley brings a unique combination of technical and marketing experience to the company. This capability fits the needs of Linear Systems, Inc., which Mr. Thompson stated plans to become a broad based communications company.

Optiflex

Fiber optics is that light-piping idea you have been reading about sometimes over the past few years. IBM uses fiber optic devices to pipe light to convenient corners of their card-reading machines, eliminating many individual lamp assemblies. Now the idea is appearing in service gear.

Amertest Products' handy little lamp consists of a conventional penlight plus a flexible fiber optic cable. The cable really is flexible enough to tie into knots. It's a nonconductor, too, so that you can poke it into live circuits and assemblies without concern about new unwanted connections inside the gear or out to the real world, including yourself. Just right for getting some light into those dark corners.

Suggested list price on the Optiflex lamp is $4.65. For additional data inquire at your dealer's, or write to Amertest Products Corp., 144-27 Jamaica Ave., Jamaica, L.I., N.Y. 11435.

AMD Microphone

If you are interested in outdoor amateur operating, serious on-location tape recording, in speech work, or public speaking applications, here is a microphone that may well be a Best Buy.

Since it is a cardioid microphone it has a strong null toward the cable-attachment end. This avoids crowd noise problems, and greatly alleviates the nuisance of audio feedback in public address applications.

For outdoor tape recording and amateur operating, its built-in windscreen styling reduces or eliminates the need for the frequently-seen large plastic foam cover. And the microphone's 100 to 12,000 Hz response is adequate for all speech and some musical applications.

Special connector wiring in the microphone stem offers the user a choice of 600 ohm impedance (-73 db sensitivity) or 50K ohm impedance (-54 db sensitivity.) It has an on-off switch, and comes with 20 feet of cable with a standard phone plug, and a swivel microphone stand connector.

Priced at $13.95 retail, from AMD Electronics, 663 Dowd Ave., Elizabeth, N.J. 07201.

FCC Recognizes Thailand—Almost

The FCC has announced that it is now permissable to contact stations in Thailand using U.S. calls/HS. Communications are still prohibited with the HS prefix stations.

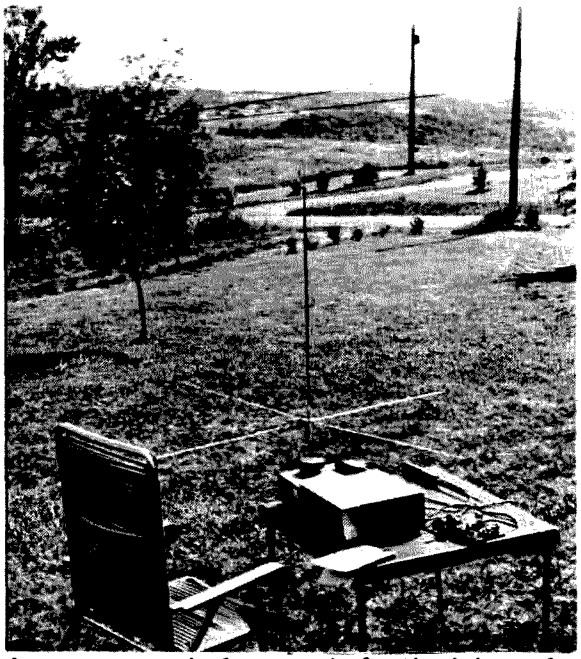
Adapting A Mobile Antenna System for Vacation Use

Bud Michaels, WB2WYO
510 High Street
Victor, New York 14564

A last-minute decision to take a rig along on vacation left me with the problem of what to use for an antenna. We would be moving from campsite to campsite every few days, so my inherent laziness precluded an elaborate antenna system. Likewise, I didn't have much enthusiasm for disturbing three years' accummulation of rust and crud to dismantle a mobile whip antenna, offered by a friend, along with a complete set of resonators.

After much consideration, the mobile system seemed the most practical, and I accepted the loan of the resonators, but struck out on my own to devise a whip and base; one that would allow me to use the resonators, yet not necessitate tying the car down at the campsite.

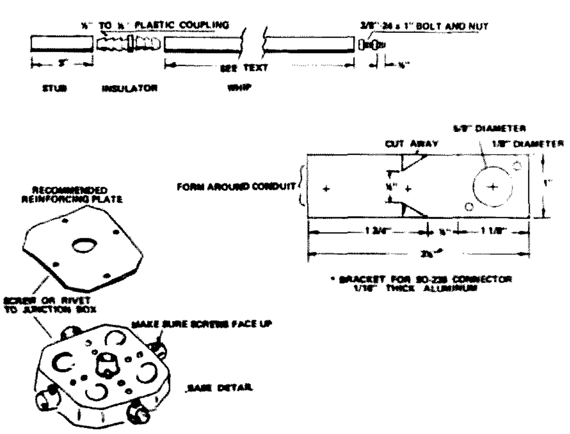
The problem was solved using EMT electrical conduit. A whip, base and supports/radials were made using ½" diameter conduit and a square junction box. The whole affair cost less than $5.00 and proved to be a truly effective and simple antenna system. In fact, I'm collecting my own set of resonators in anticipation of next year's vacation.



Antenna set up in front yard of author's home for SWR measurements. Additional ground was required for 40-meter operation.

Making the Whip

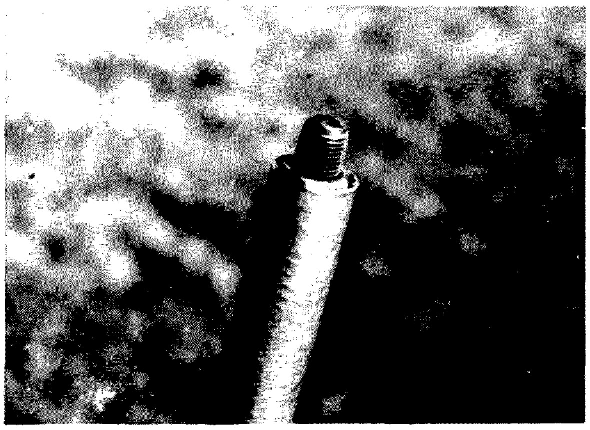
Cut a piece of ½" diameter conduit to 54". (This dimension is for Newtronics resonators. For other resonators, rely on manufacturer's specs or measure a friend's antenna.) A pipe cutter does a neater and faster job than a hacksaw. File away the burrs at both ends, then brighten up the metal inside one end of the conduit so it will take solder.



File the edges off the head of a 3/8"–24x 1" bolt, and a 3/8"–24 nut so they will fit snugly into the conduit. Thread the nut onto the bolt, leaving ½" of the bolt extending. Tin the bolt and nut, then slip them into the conduit with the nut flush with the end of the conduit. Solder them in place. This forms the means of attaching the resonators to the whip.

The whip must be insulated from the base. This is done using a ½" to ½" plastic water pipe coupling. Cut a short piece of conduit, around three inches long. Clamp this in a vise and warm with a torch until you can force the plastic coupling in. Quickly cool the assembly, lest the heat distort the coupling. Do the same with the bottom of the whip, so when finished you have the plastic coupling (our "insulator") between the whip and stub. The plastic coupling will most likely slip out of the conduit, and epoxy cement or "pop" rivets can be used to make the joint more permanent.

I found it more convenient to attach an SO-239 connector so that the coax cable could be more easily connected. Details are given for making a bracket to mount the connector. (Naturally, this idea came *after* vaca-



End view of whip showing the 3/8-24 bolt which screws into mobile-antenna resonators.

tion!) The center wire from the connector is soldered to the conduit through a hole made for the purpose. If you do not wish to use a connector, the coax can be soldered directly to the whip; the shield being soldered to the stub.

Base

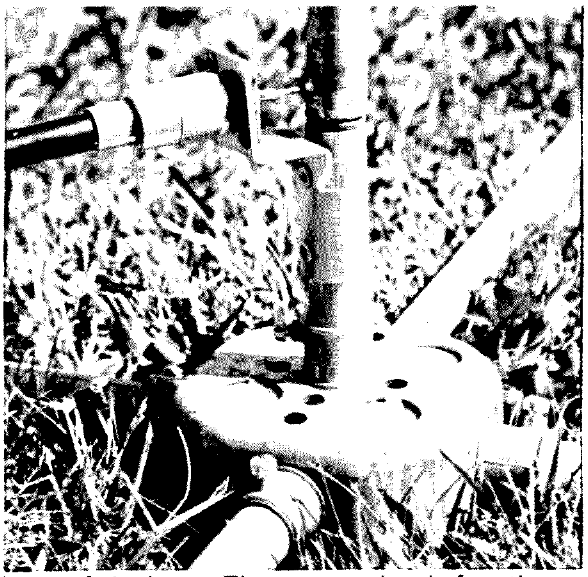
The base is made from a 4" square electrical junction box. Be sure to use one with ½" knockouts. Five ½" conduit connectors are screwed into the knockout holes, as shown, with their screw heads facing upwards. Don't overlook this simple point, otherwise, it will be awkward to disassemble the antenna for take-down. Here's another bit of hindsight: the top of the junction box is not too sturdy, owing to the knockouts stamped in the metal. Make a plate to fit over the top, as shown in the illustration. Screw or rivet this reinforcing plate to the box, then install the center connector. You will find this arrangement holds up much better, especially if you anticipate small boys will be using your antenna for a "Maypole."

Support—Radials

The four supports/radials are made from five foot lengths of conduit. Five feet is a convenient length to carry, and two can be cut from one 10-foot length of conduit (standard length). Don't make them any shorter, or mechanical stability and antenna radiation will suffer. If you can make them longer, so much the better; especially if you intend doing any work on the 80 and 40 meter bands.

Setting Up

Using the antenna system is simplicity itself. Place the four radials into the connectors and tighten the screws securely, yet not enough to deform the conduit. Attach the whip to the center connector, then screw the resonator to the top of the whip. Follow the manufacturer's instructions for adjusting the resonator to the lowest swr. I did have trouble bringing the swr down on the 75 meter resonator, due to poor ground conditions. (After all, five foot long radials at 75 meters is a joke!) The problem was relieved somewhat following a suggestion by WA2AOD: use kitchen aluminum foil swiped from the XYL to increase the ground plane. Four 15' long strips placed under the radials helped get my signal out with acceptable performance.



View of the base. These were taken before the reinforcing plate, mentioned in the text, was added. Coax bracket is held to base with "pop" rivets.

Some Other Ideas

The success of this arrangement prompted me to do some experimenting after we returned home. Using the same base, I made an 18' vertical antenna using one 10' section of conduit, joined with a regular ½"-to-½" coupling. The antenna was base loaded with a coil. While the junction of the two lengths of conduit was not the strongest, I did manage to keep the antenna up all weekend and worked quite a few stations on 80 and 40 meter CW. (This, by the way, was done after the junction box top was reinforced as described above.) As a practical limit, it seems that 20' is the maximum height for conduit "verticals" because of the lack of rigidity at the joints. If you could come up with a stronger joint, I imagine these might serve admirably for field day use, with a minimum of guying.

...WB2WYO

LETTERS

This is in response to your letter of February 19, 1969, concerning the implementation of the second phase of the incentive licensing frequency reservations. In establishing the time schedule for the reservations of frequencies in Docket 15928, the Commission states that "Notwithstanding this schedule, the Commission intends careful review and if it is determined that there is insufficient occupancy of any part of the reserved frequency segments, then the effective date of the implementation date will necessarily be stayed in whole or in part, as appropriate." This statement has been reiterated in a number of Commission actions since the determination in Docket 15928.

A petition (RM 1393) is on file requesting the Commission to rescind that portion of Docket 15928 which would reserve additional frequencies in the 7 Mc/s and 14 Mc/s bands for Extra Class licensees. As previously stated, the Commission will review the occupancy of the segments now reserved and determine, prior to the November 22, 1969, scheduled date for implementation of the second frequency reservation, whether additional reservations are justified.

James E. Barr
Chief, Safety and Special Radio Services Bureau
F.C.C.

Say Wayne, I just picked up 73 and liked very much your thoughts on incentive licensing. Your positive approach to this and other matters merits careful attention. I also, of course, note your continuing license study articles, which are by far the best that have appeared in ham publications. I have been helping some hams with some of the basics for their licenses (I hope) and your articles have saved me some time of having to go into Terman or the ARRL handbook, etc. Thanks to you and your staff for publishing these articles and not just questions and answers as have some of the other magazines.

Incidently, you mention other mags saying things about 73; yes, I have read these and started adding certain things up; in fact, I went back several years in the various ham magazines and read about what is and was going on. You are right and they are wrong. Say, Wayne, do tell us all about the IARU, CQ, and other things that the amateurs are anxiously waiting to hear about. Don't be too harsh on the ARRL though, they are trying to do a good job handling all that traffic and keeping the nets on frequency and holding elections and partitioning the FCC and stuff like that there.

Bob, W7JLU
Portland, Oregon

I consider 73 to be one of the finest magazines in the amateur radio field, or indeed, in any field. This is about the fourth year I have been reading 73 regularly and I have thoroughly enjoyed each and every issue.

In comparison to the technistic platitude that is QST and the artistic mediocrity that is CQ, 73, like the farmer, is outstanding in its field. You have managed to keep a sense of humor throughout these times of peril for amateur radio in general. This is certainly a relief from the competition who feel that they can be dry and serious for 11 months out of the year if they make it up with a whopping April issue.

In summary, then, I think 73 is the greatest, and I sincerely hope it can stay that way for many years to come. Above all, I can only hope and pray that your idea that ham radio is *fun* will have a rebirth among the electronistic and scientistic types who've pervaded the radiophonic world recently. My amateur Extra Class license notwithstanding, I'd rather chew the rag about music, girls, politics, or UFO's than build my own self-neutralized class AB_2 variable-preble amplifier module with limited-fidelity sideband autonizer.

Lon J. Berman, WB2IWI/2

Open Letter

If you did not read Wayne Green's excellent editorial in March 73 Magazine, you should have! It was timely, pointed and full of meat!

Amateur Radio greatly needs the shot in the arm that a well-conducted Public Relations program could give—provided that the PR people are properly "Amateur-Radio-oriented!" ARRL desperately needs a better image with the Radio Amateur, with the public and most of all with the U.S. Government, to whom we owe our very existence—and continuence!

Wayne mentioned certain writers and a cartoonist who could help. There are many qualified writers in the field who could and would contribute articles and material to this endeavor, given the slightest opportunity—and acceptance by editors.

The capable Ray Meyers, W6MLZ, it has been reported, offered to serve ARRL as its PR man, for the customary $1 a year, plus normal operating expenses. Ray's qualifications need not be discussed here—they are completely adequate, and his devotion to Amateur Radio is well known through many years of dedicated service as a writer, lecturer, Director of ARRL, and columnist. Ray's generous offer was spurned by ARRL. Why?

ARRL's feeble attempts at PR have been through NON-licensed-Amateur personnel. Although Don Waters did a commendable job on his reporting of ARRL's status—it lacked the touch of a genuine Amateur, fighting for his own hobby.

This writer urges YOU to immediately contact your ARRL Director, by telephone or mail, and demand that ARRL institute a program of PR, with a "man in Washington" (a legalized ham-lobbyist) without delay. Let there be no referral to a committee or a "study by the Secretary to determine the need" or other typical procedural jazz by the ARRL Board. Demand that the Directors, at this meeting, set up such a program and that they follow through to see that it is done. As Green says, it may already be too late, but the effort must be made. Take action now!

In reference to Wayne Green's mention of band

occupancy, a complete study should be made, by ARRL (or someone concerned with the progress and growth of Amateur Radio) to determine what changes are necessary and vital in regard to band usage. In the opinion of this writer, (a consistently active ham for 49 hears) the CW bands are loaded when contests are on–and pretty empty at other times. The VHF bands are consistently empty, except during "openings" or contests. Ten meters, formerly the work horse of casual rag chewers, shows little occupancy now. Such an occupancy study, plus recommendations, both *qualified* and *studied*–to FCC–should result in changes, even though temporary, that would raise the occupancy of our empty bands segments and reduce the QRM in the other sections.

There is nothing sacred about FCC regulations. They can and should be changed when the need arises and without long delays, hearings and other proceedings.

ARRL should have a better relationship with FCC and be able to advise FCC when and how the band segments should be changed and redeployed! No one is served by holding to long usage concepts of the bands when it is obvious to any active ham that changes are desperately needed.

On this point, why are so many licensees who are now permitted to utilize the "restricted" segments, still holding forth in the cluttered-up sections?

A. David Middelton, W7ZC
Former ARRL Director

With reference to certain aspects of the "de W2NSD/1" article in your March issue, you may be interested in the following information.

In the April 1967 QST, there appeared a request that members advise their Directors with respect to their opinions on (1) dues; (2) freeloaders; (3) docket 15928; (4) by-laws; (5) CB liaison. I wrote my Director, Gil Crossley, and sent copies to the then Vice-Director and to Harry Dannals, Hudson Division Director, since I had a permanent QTH at my boyhood home in that area.

My letter, in part, read: "Final item–amateur radio must have adequate representation in Washington. Maybe "lobby" is a nasty word to some, but it is a recognized procedure. We desperately need it, both for our protection and advancement. I spent many years in Washington as an industrial representative, and I know how much the right word in the right ear at the right time can accomplish. Please have this considered."

I had no reply from either Harry or the V-D, at that time W3KT, but I received a very nice note from Gil, which read, in part: "Relative to representation in Washington–that is very well taken care of, with amateurs in the different departments of the government and legislative halls. What I am saying is not generally taken by many amateurs but things can't happen without our knowing it at once. I certainly felt the same before I was on the Board. For example, Bob Booth our legal advisor is president of the legal organization that practices before the FCC. To have a so-called lobby, it would have to be registered and we would likely lose our tax exempt statis." (Sic)

Now, it seems to me that he simply does not understand what a lobbyist does, in the sense of the scope of the job beyond collection of information. So, I wonder if the other Directors may not likewise lack that understanding? If so, how can the question possibly receive adequate consideration?

Also, I thought that the tax-exemption matter might be of interest to you. In any event, I don't recall that "lobbying," in any context, was considered at the subsequent Board of Directors meeting.

Al Smith, W2AFJ/K3ZMS
Doylestown, Pennsylvania

Like you say, the rush to Extra Class doesn't seem to have materialized; this is going to crowd hell out of the segments assigned to General Class. I have talked with holders of Extra Class tickets and they tell me that most, if not all, their cronies are General Class; therefore, they will be using the upper segments in order to chat with them. This is going to give our friend, Chop Chop, a chance to say the Extra Class segments are not being utilized to any great extent, so, like 11 meters, we may expect to lose that portion of the band to other services. Those Extra Class tickets should have been allowed to use a part of the CW portion for phone. Then, maybe there would have been a bit more incentive, nicht wahr?

Bert Berthelsen, W5IOI
Ormond Beach, Florida

I appreciate the FB job on your Advanced theory articles—and now the Extra. *Many tnx!*

Guys older in years (but not old timers in Ham Radio) such as myself, need this stuff interpreted and written as you are doing.

Bill, WA8AME
(Now Advanced Class!)

73 is excellent, no rubbishy padding (i.e., DX reports). Please keep up the good work! Over in the U.K., we find it very difficult to find *practical* articles on the advanced semi-conductor devices, i.e., I.C.'s and FET's etc., so your really great articles are appreciated. A couple of years ago, I subscribed to QST, but in one full year, I personally found only one article (on Ferrite Toroids) of real value, and needless to say, you had already covered them (and better) six months earlier!! Yes! I guess I'm sold on 73.

73 and all the best for 1969.

Chas, 93RNV
Cheshire, England

I first went on the air with the call 2-KJ in Brooklyn, N.Y., in 1919, and have been on and off ever since. In almost fifty-years of ham activity, I have never encountered a situation such as now exists in Phoenix, Arizona, on the twenty meter band, approximately 14.340 MHz.

Time after time, I have heard K7GRU come on and create what appears to be deliberate interference. Very often he interferes with the operation of the Coast Guard Net trying to run overseas welfare traffic; he indulges in invective and name calling. He settles down on QSO's in progress and talks of his technical excellence and the efficiency of his equipment yet his signal is often ten kHz wide. There is more but this is enough to give you my thoughts on the matter. If anyone ever tried to give amateur radio a bad name, it is he.

A. R. Taylor, WA5WMJ
Gravette, Arkansas

Every project that I have built from "73" Magazine has worked the first time. Can't say the same for any other magazine. The best one of all was "A Beginner's Receiver," 73 June 1963.

I would also like to see a BC-454 or BC-455 conversion to 14 MHz to 17 MHz or 15 MHz to 18 MHz. Maybe some reader would forward his conversion to me?

I believe you have the best magazine going. Maybe Playboy is better, but they don't have too many radio articles.

Dick Heydt
P.O. Box 222
East Granby, Conn. 06026

Just a word of appreciation for the series on the Advanced Class. Recently a friend of mine called to say that he was going to Kansas City in about a week to try for the Extra license and suggested that I go along and try for the Advanced. I did an intensive study using the series from 73 and passed with few errors. The series was interesting, (unusual for such a technical subject) well-written, and very practical. I am looking forward to the Extra Class series.

Horton Presley, K0HVK
Ottawa, Kansas

73 came in late this month and I miss the letters from your readers.

I believe your graphs showing the negative results of incentive licensing only proves my contention that the majority of US amateurs do not approve of this and are not going to support it. They feel as I do, the only way now to defeat it is to ignore it and the FCC will in the near future rescind it.

They know it was instigated by a small selfish group that had undue influence with the FCC through the ARRL for the express purpose of giving themselves an advantage of QRM free operating frequencies.

The vast majority of amateurs that have carefully thought this issue out know that passing the advanced and extra class exams will not accomplish any better operating practices or will it clean up the violations being practiced on our bands. So it has no useful purpose.

You have the wrong attitude Wayne. Laws can be changed—remember prohibition?

The FCC said they would review the problem after it had been in use and would if the frequencies were not used sufficiently rescind it. Certainly only 6000 amateurs out of a quarter of a million does not constitute a sufficient number to justify any special frequencies assigned to them. So the majority of amateurs have in my opinion decided this was unjustly forced upon them and that the only way now to defeat it is to resign from the ARRL and refuse to take the new tests in protest and to hope the FCC will see the mistake they have made.

The FCC has unfairly discriminated against the CW operator. They now make him take the most complex theory tests (both Advanced and Extra) when he is using the simplest of equipment, just to get the full use of the CW frequencies he is or was assigned. I am a CW man.

This irresponsible action of the ARRL has accomplished only one thing and that is it has emphasized to the commercial interests and to the forthcoming convention of frequency allocations that the amateur bands are too large and that the amateur can afford to lose some of his frequencies because the ARRL feels the great majority of amateurs can be forced into a much smaller segment of the bands that we now hold. This is the interpretation the commercial interests will give to this and use it against the amateur frequency assignments.

I was a member of the ARRL back in the early

20's and I knew Percy Maxim personally and I sure liked the old man. He would not have approved this action of the ARRL.

The ARRL knew they had made a mistake after they made this proposal but they were not big enough to admit it and went along with the hope the FCC would have the good sense not to approve it. This was proved by the futile way they have tried to justify and defend it even saying they did it just to create a controversy. How insane has an organization to become before it is committed? They don't have to be, they have committed suicide by themselves—"Give a fool enough rope, etc."

Wayne, for your information, this incentive licensing has done much harm in many ways. I would like to mention a few instances that have come to my attention. I have a local friend that has been a ham for many, many years; he is sixty years old and has been very active in the past in the local radio club, on the TVI committee, etc., and has given many hours of code and theory classes and has many local hams that owe him for their tickets. He has always been a general and is a retired dentist. Well, he went to Miami and took the Extra exam. He passed the CW but failed the theory. This was very embarrassing to him and he has given up completely—I never hear him on the air anymore and he gave me four big boxes of parts and equipment—the contents of his junk box. You see, the ARRL has caused us to lose a very fine amateur. This is just one case I know about, there must be thousands of others that have just given up because of this irresponsible act of the ARRL and the FCC. In the interest of amateur radio, I think you should still fight for the rescinding of this provision that has been forced on us.

One of your arguments can be that amateur radio is truly world-wide and international and that it is unfair to the USA amateurs to be restricted by special examination from use of parts of the bands that other countries do not restrict. Amateur radio is international and the rules should be international—this is only fair play.

For example, this has brought about another problem that of reciprocal licensing. We have here in South Florida a lot of retired Canadian hams that live here permanently but because they are Canadians, have their VE calls and the Ft. Lauderdale, Fla., USA, address in the Canadian call book. Now, with this incentive licensing that they do not have in Canada they do not know what parts of the bands they can use legally in the US. VE3CI/W4 Heith Love talked with me about this situation the other day; it affects him. So you see, this unnecessary act is causing many problems that did not exist before and have no need to exist now—it should be rescinded.

Needless to say, I am no longer a member of the ARRL. An organization that willfully disrespects the majority of its membership is not a democratic organization.

Many of those 6000 Extra Class are old timers that grandfathered in and have not been on the air for many years; we have several locally.

Wayne, I wonder what has happened to the old steam in you—why has the fire gone out? Have you given up and joined the opposition? God help us!

George Taylor, W4PZS
1133 S.W. Fifth Place
Fort Lauderdale, Florida

In reference to your de W2NSD/1 editorial in the January issue, you should have a divorce vic-

tim's net. I don't think you would have any trouble in getting divorced people to talk. The QSO would start: "Let me tell you about my case—it's different." This type of QSO would last for hours and far into the morning.

Your mention of missionaries on the ham bands recalls to mind the fact that the Seventh-day Adventists (who were the cause of my troubles) did have and probably still do have, Bible networks. I used to get a kick out of listening to some unsuspecting ham joining the round table, and then getting the drift of what was going on—pulling out but fast.

A psychiatrist once said that most marriages were *dull*. I would challenge his statement and say that most successful marriages are *comfortable*. Marriages that are *exciting* quite often become *tiresome* and don't last too long.

So, perhaps QSO's are not so *dull* but *comfortable* and *most* hams like it that way.

George Partis, W6GHV
Founder & Executive Director
United States Divorce Reform, Inc.
Kenwood, California 95452

Each article published brings quite a mail bag from interested hams seeking further information or confirmation, not all of whom think to include an SASE (or even postage). The 4-BTV evaluation article netted me 22 such letters, mostly from people wanting to know if I really meant the antenna was that good (one old timer in Iowa asked bluntly, "What am I supposed to do with all that goddam wire,"—he got a polite reply and a sketch of a proposed layout of the radials for his small lot. 'The Gentrac' article has kept my mailbox busy—one from a missionary radio technician in the Amazon jungle who was attempting to build a Gentrac for his work and needed some advice.

Peter Lovelock, W6AJZ
Santa Monica, California

I would like to introduce a new and different net—The Handicappers Information Net. This net is now meeting Mondays, Wednesdays, and Fridays from 2000 to 2100 GMT on 7270 kHz. Although this is primarily a net for handicapped persons, all amateurs are invited to participate. Our goals are to aid handicapped persons in their daily personal problems, to help handicapped amateurs advance their class of license, and to interest and assist other handicapped people in obtaining an amateur license.

To make a success of our goals we need the help of many amateurs. Volunteers are needed to help set up stations for newly licensed handicapped amateurs and to give advice and encouragement to those studying for their licenses. Many members have donated various pieces of equipment while others have offered the loan of equipment for use by handicapped members.

At the present time we are helping three future members obtain their Novice licenses. In order to help more we need your help. For further information, check into the net or contact Otto Huggins, WA5TIK, Assistant Net Manager, L. E. "Gib" Gibbins, W5PCN, Equipment Co-ordinator, Sandy McDowell, W5QZY, or me.

This is a chance to give to others the pleasure of ham radio that you now enjoy and of having the personal satisfaction of knowing you have helped others.

Kathleen Wilson, WA5QOR
Net Manager
Handicappers Information Net

In your interesting article on Tesla you mentioned some references. Where? What did you do with them?

It has been a number of years since I have written to you, nevertheless, I buy 73 and read de W2NSD/1 your editorials beat any other Ham Radio magazine on the market from QST to them all. I particularly have enjoyed your excursion around differents part of the globe, especially Europe. I would like to call your attention to January's issue on page 100, European VHF, by Lee Grimes, who is stationed there in Berlin. This article was one of the best I ever read; it was most informative. I am sure that there are thousands of us who enjoyed this article. The Editorial Liberties in the February issue brought some snickers about the ARRL requesting character references from some other Hams in order to renew your license or obtain a Ham license. Your article on Nikola Tesla and his contribution to electronics was well appreciated; however, I know I will never have the brains to pass the Extra Class exam. I am satisfied with the small amount of the frequency band that I'm allowed to operate on. I agree that the incentive deal didn't change the picture one iota as far as I can see.

Kenneth Mahoney, K6OPG

Reference is made to your letter of 7 February 1969 concerning amateur radio operations from Navassa Island.

Navassa Island is a small, rocky island with sheer sides extremely inhospitable in nature. It is uninhabited, lacks any source of potable water, and the terrain is rough and broken. The only installation on the island is an automated lighthouse maintained by the Coast Guard. A landing can only be accomplished from a small boat and requires scaling a 40-foot Jacobs ladder, which is an especially hazardous undertaking.

While we recognize that a well outfitted and organized group could reduce the hazards of visiting Navassa to some extent, we would not be able to supervise the operations proposed to the degree that would be necessary to assure the reasonable safety of the individuals concerned. Since the island is under the jurisdiction of the Coast Guard,

we would retain responsibility for the safety and well-being of visitors in the same way as we would for visitors to any other Coast Guard property.

With the exception of government employees on official business, since 1963 it has been the judgment of the Coast Guard that all requests from individuals to visit Navassa Island should be denied. There have been no new developments which would prompt us to change our position. The reasons for this position are several. In addition to the dangers present in effecting a landing together with the complete lack of facilities or means of sustenance, the location remote from civilization would make any visitor a likely Search and Rescue case. Furthermore, Haiti lays claim to Navassa as a Haitian dependency and refuses to recognize it as a U.S. territory. In view of this political situation a visit with radio equipment could easily be misinterpreted, as it was recently in the Middle East.

Moreover, call sign prefix "KC4" that was available for assignment to amateur stations has been deleted by the FCC, and the Commission no longer classes Navassa as a separate country for "DX" awards.

Therefore, the Coast Guard feels that, due to all of the surrounding circumstances, it is in the best interest of all concerned to deny individuals the authority to visit Navassa for any purpose save official business. Consequently, we must deny your request.

If the Coast Guard can provide any additional information or be of further assistance, please feel free to call.

P. E. Trimble
Vice Admiral, U.S. Coast Guard
Acting Commandant

(FCC is running DXCC for the ARRL now, I see....ed.)

Lines Created on the Passing of Robert Evans, W3NO

We say 73 to our dear friend, and strain to hear SK
For W3NO passes only to continue life,
Perhaps not far away.
We, here on this plane, shall hear that call again,
And know it bears another consciousness that we knew,
But still aware the old exists in us.
For what new wavelength, frequency or harmony do we seek,
In what direction do we steer within the universal spectrum,
To next discern that faint CQ DX?
Do our communicators search to find a device,
A demodulator to transform that invarient part of him,
That we might understand a message coming through?
We are beings of vibrations, constant motion, ever change.
Have 3FT and 3NO become as One, or only part of us?
The answer might be found within the realm of transformation of ourselves.
Amateurs have played their part in great discovery.
There awaits uncovery of a cosmic law by their probing mind.
A few, perhaps, will make the search and answers find.
Meanwhile, we really mean not to say farewell, but simply wait for us.
We're not far behind,
For how now he measures time.

S. Lee Maulsby, W3RKK

Million Dollar Suit Progress Report

As previously reported, the preliminary hearing before Judge Lieb in Federal Court in Tampa on Jan. 8th produced nothing concrete. The Judge asked for further briefs of law from both attorneys, to help him make a determination as to the proper disposition of the base. As a result, W4GJO's attorney has filed two further briefs, approximating 35 pages of well-researched law.

The opposing lawyers are asking that the case be remanded to Circuit Court in Sarasota County for trial on the "Nuisance," "electronic invasion of privacy" and million dollar damage charges. Our position is that Circuit Court has no jurisdiction in a matter involving a Federally granted privilege and responsibility. We also feel that it belongs in *no* court at this time, since the complainant fails to allege that he has exhausted his administrative remedies before the FCC. (Although, in fact, the FCC Field Engineers did investigate before the suit was ever filed, and gave W4GJO a clean bill.) We feel that the case should be dismissed by the Federal Judge, leaving the complainant free to take it to the FCC. Only if the FCC had found W4GJO at fault, and had he failed to comply with FCC orders, should the Federal Court be involved in enforcing an order of the FCC. This is clearly not the case. If the complainant feels the FCC ruling against him is in error, he should take it to Federal Appeals Court in Washington, D.C. We are currently awaiting the ruling from Judge Lieb.

In the meantime, our case against the complainant remains in the local court. The temporary injunction against the TVI complainant has been lifted, in return for sworn agreement that he will do nothing further to harass W5GJO or his family. There will probably be further hearings in this case before it comes to trial.

ARRL has provided much helpful material, but they feel that they cannot participate directly or financially until and unless the case comes to trial in a Federal Appeals court. Mr. Bob Booth, the ARRL General Counsel, continues to monitor the case closely, and is being provided with complete files of the great volume of paper-work involved in the case.

Good attorneys don't come cheap, and expenses to date exceed $2500. Few individual hams could handle this, but together it should be easy to finance fighting our case. Thanks to 73 Magazine, Florida DX Report, the QCWA News and many others, many contributions have been received, and needless to say, they are greatly appreciated. It's impossible to estimate what total costs may be. The case could be dismissed soon and no appeal made, or it could go on into other or higher courts and drag on indefinitely!

The Sarasota Amateur Radio Association, Inc., P. O. Box 3323, Sarasota, Florida 33578 has set up and is administering a fund to help underwrite legal costs in the case. Your help is urgently requested! Any unused funds will be returned to contributors furnishing names and addresses.

Not only is the future of ham radio as we know it today at stake, but it appears that this case strikes at the very power of the FCC to regulate! *Your* right to operate your amateur radio station without intimidation is involved!

Caveat Emptor?

★ Price—$2 per 25 words for non-commercial ads; $10 per 25 words for business ventures. No display ads or agency discount. Include your check with order.

★ Deadline for ads is the 1st of the month two months prior to publication. For example: January 1st is the deadline for the March issue which will be mailed on the 10th of February.

The Atlanta Radio Club will hold its annual Hamfest on June 14 & 15 at the North DeKalb Shopping Center, Atlanta, Georgia. This promises to be one of the biggest and best Hamfests ever held in Atlanta. In addition to regular Hamfest activities, we are aiming for the largest amount of equipment to be bought, traded and sold, of any Hamfest in the Southeastern United States. There will be plenty of parking spaces for trucks and station wagons, along with inside space for displays. Further details may be obtained by writing John Fearon, 3384 Peachtree Rd., N.E., Suite 705, Atlanta, Ga. 30326.

The East Coast VHF Society will operate station WA2WEB/1 on 432 MHz from Mt. Equinox, Vermont on June 21 and 22, 1969. The express purpose of the expedition is to provide amateurs on the East Coast of the United States with the opportunity of contacting the state of Vermont on 432 MHz. The station will be on the air for approximately 24 hours for scheduled and non-scheduled contacts. Schedules are requested from interested amateurs. Write: East Coast VHF Society, P.O.Box 1263, Paterson, N.J. 07509. All correspondence and schedules will be confirmed prior to expedition.

Regulated Power Supply Kits, .6-4 AMP, $2.75 to $8.50. Zeners, thermistors, 25¢. 10A Triac, $1.75. Diodes, 5¢. Nixie, $5.00. Decimal Counter Kits, $3.50. Catalog. Murphy, 204 Roslyn Ave., Carle Place, N.Y. 11514.

AUCTION—June 8th, Manchester Radio Club at Tower Hill, Candia, N.H.—Map and information S.A.S.E. W1HPM, P.O.Box 661, Manchester, N.H. 03105.

How to Wrinkle a Wrinkle Finish

When I build, I seldom strive for compactness, since I like lots of room for modifications, pruning, and possible additional circuitry. I also like the neat appearance of rack mounting, and I'm fortunate in having a free source of 1/8" aluminum from which to fashion panels. Finally, I have predilection for black wrinkle finish. Don't ask me why—I just dig it.

In the past I've tried about every make of black wrinkle enamel in spray can I could find, and the results were never encouraging. Many of you have probably had similar experiences. It doesn't wrinkle. It doesn't dry for three days, and is soft enough to scratch with your fingernail for two or three weeks. At best, it looks like a sloppy job using standard spray enamel.

Finally, I hit on a solution. Follow the directions on the can: two *heavy* coats three minutes apart. Let it stand for about ten minutes after the second coat, and while it's standing, fire up the XYL's oven to 250 degrees. Pop in the panel and bake it for a good two hours. It thoroughly stinks up the house, but the result is beautiful even wrinkling that's as hard as any professional paint job.

Bob Grenell, W8RHR

73 Magazine is published by 73, Inc., Peterborough, N.H. 03458. Subscription rate: $12.00 for Three years, $6.00 for one year. Second Class Postage paid at Peterborough, New Hampshire, and at additional mailing offices. Printed at Pontiac, Illinois, U.S. Postmaster, please send form 3579 to 73 Magazine, Peterborough, New Hampshire 03458. Address label cypher: your call letters should follow your name. If we've had to make up a call just drop us a note and we'll change it to your real call. The number under the call is our code for the last issue on your subscription. The first number is the month, the second, the year of the last issue. 50 would indicate expiration with May 1970. Renewal notices are prepared ahead of time and you may receive one or two after your subscription has been renewed. View this situation with humor and tolerance. Tell your friends about it, if you must, but don't feel it necessary to tell us, we already know all too well about it.

...de W2NSD/1

Wayne Green

Getting away from the seemingly uncontrolled confusion that gives birth each month to a new issue of 73 gave me a chance to give a little more thought to the role that amateur radio is playing in the world today. Lin and I had a few days to dash off for a short "vacation" before Kayla left us to get married, so we decided to go on one of those packaged European ski tours where they include a car in the deal. It was our first skiing in Europe.

One day of skiing in St. Anton, Austria and one in Zermatt, Switzerland forever cured me of wanting to ski in Europe. I waited for over five hours in Zermatt on the lift lines, some of which rivalled the mob scene I witnessed a few years ago when several thousand women became a screeching, unthinking mass trying to touch the Pope. It was worse than any subway crush in New York. Here we have lift lines, there they have lift mobs.

So, while Lin was busy memorizing the galleries, palaces and castles of Florence and Venice, I ate pasta and tried to put things into perspective.

Frankly, the more I think about the problems we have in amateur radio today, the more concerned I get. Amateur radio is far more important than I suspect anyone realizes. To most of us involved in it, amateur radio is a hobby for having fun. It most certainly is that. If it wasn't it wouldn't exist. Even the reasons given for the existence of amateur radio in the FCC regulations don't give the single, most important reason for amateur radio to exist.

Those FCC purposes for amateur radio have clouded the issue. They have focused attention on PICON, on emergency traffic handling, on technical developments, on incentive licensing, etc. While we can't dismiss these factors, they are very far from being the most important.

As I see it, and I'll be blunt, unless we get amateur radio moving ahead, get it expanding as it should, serious and permanent damage will be done to the United States. There is no question in my mind that amateur radio is the most important hobby in the world, by a wide margin.

When Russia sent up Sputnik and we found ourselves obviously second in the space race, our politicians made much hay over the missile gap and for a while there was a lot of worry about how to get our teenagers interested in getting into the sciences. We are, today, keeping up pretty well with our missiles and technology. But all of us recognize fully that electronics is a fast growing field and that as it expands we will have to have perhaps ten times as many engineers and technicians as we have today in just a few years.

You don't start being an engineer in middle age, you start in your teens. And, you don't start being an engineer in your teens if you are spending your time protesting, roving with a street gang, or dropping out. The reason we are able to have the number of engineers and technicians that we do today is very largely due to the influence of amateur radio on two or three hundred thousand teenagers in the last 50 years. Well over 80% of the high school hams go on to work in electronics and communications. What do you think would happen to our electronics industry if every man who got started via ham radio were to drop out?

Now, at a time when we should be doing everything in our power to see that amateur radio is exploding with new hams, we have ground to a halt. We should be working overtime to attract newcomers into our hobby. We should be setting up talks and demonstrations in high schools. We should be organizing code and theory classes in the schools. We should see that ham magazines and books are in the school libraries. We should put on public demonstrations of ham radio. Even notes on public bulletin boards suggesting that interested teenagers come over and see your station will help.

And, once we have them started we have to do everything we can to keep them from dropping out. Don't let them settle for just going part way. Don't let them drop out and

(continued on page 118)

New Ways of Generating Microwave Power

Charles S. Jones, K3PBY
181 Pennsylvania Avenue
Clairton, Pennsylvania 15025

It is now more than a quarter of a century since a small group of physicists at the Bell Telephone Laboratory invented the transistor. The enormous technical progress that has been made in the art of semiconductor electronics during these years has been extraordinary. The field of solid state technology is moving so fast that one has difficulty in keeping up with current developments. This is especially true in the area of microwave technology. Here, semiconductors are making monumental strides that are causing a revolution in the design of microwave circuitry.

In this article I will discuss some of the most recent aspects of solid state application growth in the field of microwave power generation. Since the theory of operation of these devices is rather complex and involved, I have not devoted much attention to this area of thought. My main purpose is to shed light on what to expect from solid state microwave devices in the near future.

Today, one of the most versatile semiconductor materials is gallium arsenide. Its use has contributed greatly to the development of numerous solid state microwave devices. Transistors, varactors, microwave diodes and many other ultra-high devices are possible with gallium arsenide.

Just recently, another remarkable application for this multi-faceted semiconductor material was unearthed. It was discovered that a tiny chip of gallium arsenide can be made to emit microwaves simply by applying a steady dc voltage across it. This phenomenon, known as the Gunn Effect, is expected to revolutionize microwave technology. Ever since J. B. Gunn of the International Business Machine Corporation discovered this new solid state source of microwave radiation, engineers have been waiting for the potentially low-cost semiconductor to be made practical. All that would be required for a microwave source of power then would be a battery, a resonant cavity and the small chip of gallium arsenide. No longer would a microwave system require a klystron and its associated bulky power supply, or a radio-frequency oscillator with several stages of harmonic varactor multipliers, or a power limited microwave transistor.

Between the valence and conduction levels there is an energy level called the "forbidden" or depletion level, because no electron ever contains that exact energy level. The reason is not know, but the fact is that nature has prohibited certain energy levels.

Like silicon and germanium, gallium arsenide owes its semiconducting characteristics to the structure of its energy bands. These energy bands are shown in Fig. 1. Of course the depletion region in this illustration is amplified to a great extent. There is no sharp division between the crystal regions and the depletion region. As you move out from the junction between the P- and N-areas the charge density becomes less and less, and the number of charge carriers more and more.

At ordinary room temperature there will be very few electrons which will possess enough energy to cross the depletion region and therefore create a current flow. However, if the semiconductor material is doped with certain impurity atoms, electrons can be added at energy levels which are just below the conduction band. Very little energy is then required to boost these electrons across the depletion region and produce a flow of current.

These materials which are added to the semiconductor material are called donar impurities because each atom donates an

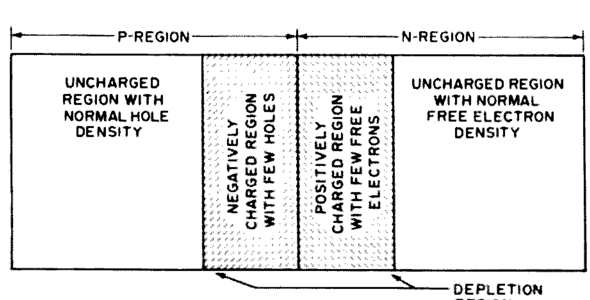

Fig. 1. The energy bands of a diode.

electron. This creates an N-type semiconductor material. Similarly, the semiconductor material can be made P-type by adding acceptor impurities. These will produce empty energy levels just above the top of the valence band. Here, the electrons can be driven out of the valence band into them, leaving holes behind.

To change the allegory a bit, let's see what's currently being accomplished with Gunn oscillators as microwave power generators. The field is moving so rapidly that it is difficult to pin down specific power and frequency figures at the present state of the art. A sample of some of the more recent lab results with Gunn oscillators are as follows: 1.5 watts peak power in the X band at Motorola Inc., Arizona; 140 milliwatts of CW at 6 gigahertz by Texas Instruments; and a full gallon of peak power at 1 gigahertz by the NASA Electronic Research Center, Cambridge, Mass.

With a good many experimental systems already successfully tested, the promise of achieving a low-cost microwave power generator is gradually nearing fulfillment. At the present time a British firm, Mullard Ltd., is marketing such a device for experimental purposes. Priced at 175 dollars, it is available in sample quantities. Granted, this is a pretty steep price tag. Keep in mind though that the first *rf* power transistors for the 80 meter band cost a pretty penny at first; now they can be purchased for less than a dollar.

Up to the present the high cost of vacuum-tube microwave sources (a small klystron and its power supply cost about a hundred dollars) and the complexity of system has seriously limited amateur radio experimentation in the microwave frequency range. The development of an extremely simple and economical microwave power generator, such as the Gunn oscillator, should do much to open the way to much more use of these frequencies by radio amateurs.

The Gunn oscillator is not the only new solid state device that looks promising as a generator of microwave power. Other semiconductor devices, such as avalanche-transit time diodes, are creating power-frequency combinations never before accomplished in solid state circuitry in the microwaves. Avalanche-transit time diodes are junction devices that depend for their operation on "avalanche breakdown", that is, the creation of extra charge carriers by collisions with atoms. As with the Gunn oscillator, they are able to amplify and oscillate due to their negative resistance characteristics.

As a class, avalanche-transit time diodes offer promise of reasonable power outputs at reasonable efficiencies in the range from a few gigahertz to many tens of gigahertz. Over much of this range they will be in direct competition with bulk gallium arsenide Gunn oscillators. Thus far, the tunnel diode has been out-distanced as a microwave power generator by both the avalanche-transit time diode and the Gunn oscillator. The avalanche-transit time diodes are expected to undergo a tenfold improvement within the next couple of years. Within five years, CW power output of one watt at 20 gigahertz may be commonplace.

At this time you are probably very curious as to how this phenomenon occurs. In this respect you aren't alone because a lot of engineers are wondering the same thing! The main features of the Gunn Effect now seem to be understood, but there is still a considerable amount of research work continuing in order to completely understand its behavior.

In a very basic sense, the operation of the Gunn oscillator can be explained as follows. When the dc voltage across a tiny crystal of gallium arsenide is slowly increased, there is a certain critical voltage where the semiconductor suddenly begins to produce a high-frequency oscillation. Capacitive probe measurements conducted by Gunn indicated that a dipole layer was moving through the semiconductor at a terrific velocity; about ten million centimeters per second. Gunn also observed that the time required for one complete pass through the semiconductor material corresponded to the period of the oscillations. For example, a chip of gallium arsenide that is 0.01 centimeters long oscillated at a frequency of one gigahertz.

An explanation of how gallium arsenide behaves is not as simple as for other more conventional semiconductor materials such as silicon and germanium. It requires our understanding quantum mechanics. These are the laws that govern atoms and electrons and the basic make-up of our physical world.

Within an atom of semiconductor material, all electrons exist in one of two energy states. Some are locked in an orbit and swing around the central structure of the atom at the speed of light. These electrons are said to be in the valence energy band. Others are free to move at random between the atoms of the crystal structure.

These electrons are able to carry current when an electric field is applied. These electrons are said to be in the conduction energy band. The word "energy" is repeated to emplasize that the electrons are constantly in motion, no matter what state they are in at the time.

Once the electrons are free in their bands, they can move under the influence of an electric field. The amount of current flow that will take place depends on the mobility of each type of charge carrier. The electrons are generally more mobile than holes.

The gallium arsenide conduction band has two valleys separated by a small energy gap. The electrons in the lower-energy valley have a greater degree of mobility than those in the upper-energy valley. When the voltage across a crystal of gallium arsenide is increased, there is a greater number of electrons excited into the upper (lower mobility) valley. As a result, the resistivity of the semiconducting material will increase as the voltage is increased.

When there are more electrons in the upper valley area than those in the lower valley area, the semiconductor assumes a negative resistance characteristic. Not all semiconductor materials have this distinctive feature.

To illustrate what is meant by negative resistance, consider the graphs given in **Fig. 2**. A normal conductor of electricity has a positive resistance in the sense that the current passing through it increases with increasing applied voltage (Fig. 2A). In gallium arsenide it is possible to have situation in which Ohm's law does not hold true; the current first increases with increasing applied voltage but then decreases with increasing voltage (**Fig. 2B**). The area where the current is decreasing as the voltage is increasing is called the negative resistance region of the semiconductor material.

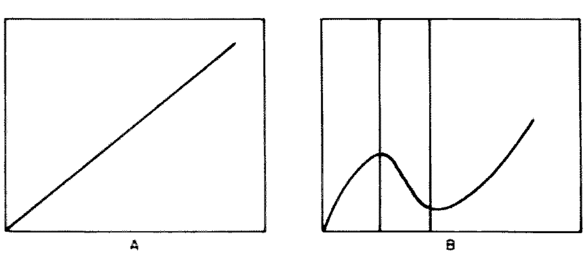

Fig. 2. The theory of positive and negative resistance are illustrated in these two graphs. A normal conductor of electricity has a positive resistance since the current passing through it increases with increasing applied voltage (Fig. 2A). In some semiconductor materials it is possible to have a situation in which the current first increases with increasing voltage but then decreases with increasing voltage (Fig. 2B). The area where the current is decreasing as the voltage is increasing is called the negative resistance region (shaded).

(courtesy Scientific American)

A chip of gallium arsenide is capable of oscillation and amplification at extremely high frequencies because of its negative resistance characteristics. Any circuit having feedback can be made to oscillate if its losses, which are positive reactances, are completely overcome. Negative resistance accomplishes this by exceeding the losses. This makes it possible for energy, once it starts moving in the circuit, to keep moving indefinitely. A circuit with enough negative resistance can overcome its losses. The opposite of loss is gain – or amplification!

Conclusion

There have been a great many promising proposals and suggested applications for these new semiconductor devices passed about in engineering circles. Some of them have advanced beyond the lab, others are still in the embryonic stages. With all the applications now being explored, it is clear that economical solid state devices for generating microwave power have passed the stage of being a lab stunt and entered the stage of becoming a beneficial addition to microwave technology. We can never know when some new insight or experimental breakthrough will bring additional advances in this field. I hope that it is not too optimistic to conclude that these new semiconductor devices will bring about a substantial increase in the use of the microwave frequency spectrum by radio amateurs in the not-too-distant future. In this article I have tried to tickle your imagination with some of the seeds of ideas that are destined to do just that.

Loaded Coat Hangers For Two Meters

Having recently acquired a Benton Harbor "lunch pail" of the two-meter variety, I decided to try my hand on that band. However, being a poor college student living in a tiny apartment, I was hard pressed for an antenna.

The antenna I needed had to be indoors and, therefore, small. Lack of money meant it had to be cheap. And, I had to reach the local two-meter gang.

A dipole and a whip proved unsuccessful. A ground plane seemed to be the answer. Five coat hangers and two coax connectors later, I had my antenna.

The coat hangers were cut into 20 inch straight lengths, with a loop bent in one end of each length. Four of the lengths were bolted through the loops to the top side of an SO-239 and bent down. The remaining wire was soldered into the center of a PL-259. (Rubber sealant may be used to guard against shorting.) A loop at the top aided in hanging the antenna from the ceiling of the apartment. The best dx so far has been about 50 miles.

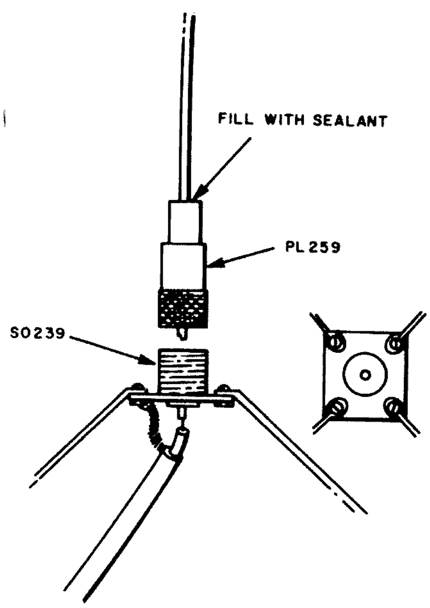

Fig. 1. Construction details for the loaded coat hanger for 2 meters.

I don't think this idea is new—but it works. *A word of caution:* Hang the antenna high enough so it won't be bumped into. You could lose an eye by running into it.

Dallas W. Williams, WAØMRG/Ø

Modification of VHF Transmitters for CW Operation

Martin J. Feeney, Jr., K1OYB
515 Central Avenue
Mt. View, Calif. 94040

Many DX contacts on the VHF bands are missed because of the lack of CW activity. This dearth of CW is usually due either to unwillingness on the part of the operator to give it a try, or because many rigs, commercial and homebrew, just don't have provision for CW operation, even in this age of enlightenment. To convince the former, I can only cite my 1250 mile QSO with W4MNT, Orlando, Florida. During this QSO I was running 70 watts, CW. I daresay this would have been difficult, if not impossible, using any other mode.

The transmitter I modified was the Tecraft TR-20, 220 MHz rig. However, the same approach can be used on many other rigs. The parts required are a DPDT toggle switch, closed circuit key jack, 7 pin miniature tube socket, .001 mF disc ceramic capacitor, OA2 VR tube, and a 15K, 10 watt adjustable resistor. Inspection of the chassis and the photographs will show the location of the components. The only critical point is to position the key jack as near as possible to the cathode pin (pin 2) of the final 6360.

The Phone-CW switch is wired so that in the Phone position the rig operates normally; in the CW position the modulation transformer secondary is shorted and the cathode circuit of the 6AQ5 modulators is opened. One part of the DPDT switch, closed in the CW position, is wired across the modulation transformer secondary. The other section is used to open the modulator circuit. This section should be open in the CW position. Unsolder the 180 ohm cathode resistor from pin 2 of the 6AQ5's. Run a wire from pin 2 of the 6AQ5's to the switch, and run another lead to the disconnected end of the cathode resistor. Tape all exposed joints.

Mount the VR tube socket and connect one end of the 15k resistor to pin 5; connect the other end of the resistor to the B+ pin on the power plug. Ground pin 2 of the VR tube socket. Replace the 6AU6 oscillator screen resistor, connected to pin 6, with a 1000 ohm, ½ watt unit. Connect one end of the resistor to pin 6 of the 6AU6 socket, and the other end to pin 5 of the VR tube socket. This will stabilize the oscillator stage, and prevent FM on Phone, and chirp on CW.

Next, mount the key jack. Wire it so that it is closed with the key out. Then unsolder pin 2 of the 6360 final stage. This is easier said than done, and may require temporary removal of other components in the area. If you are unfortunate enough to break off the pin in the process, as I was, remove the remains and replace it with a pin from

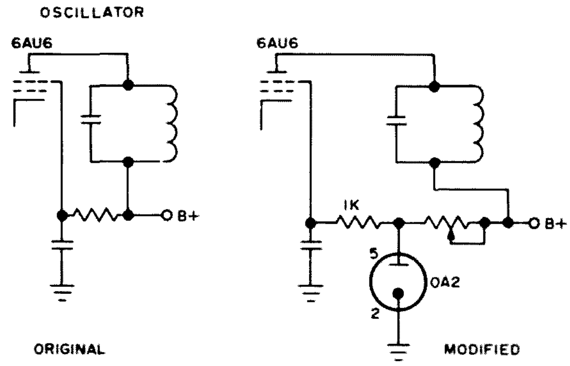

Fig. 1. Oscillator stage showing addition of VR tube.

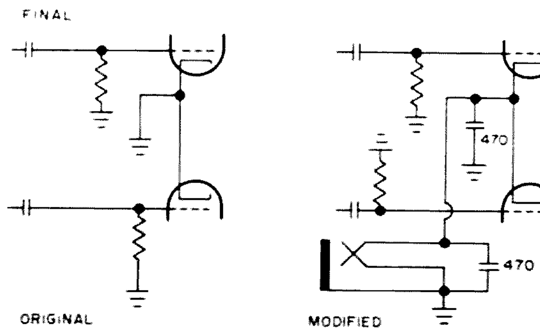

Fig. 2. Final stage indicating addition of key jack and by-pass capacitors.

another socket. Solder a 0.001 mfd disc capacitor from pin 2 to ground, and run a lead from pin 2 to the hot terminal of the key jack. Also, bypass the hot lead on the key jack to ground with a 0.001 mfd disc ceramic capacitor.

This completes the wiring. Replace all tubes; plug in an OA2, and set the adjustable resistor for about 10 ma through the OA2. With the switch in the phone position, the rig should tune up normally. In the CW position, the meter readings and the output should be somewhat higher. This is because the modulator load is removed from the power supply, causing the voltage to increase, and there is no longer a B+ drop across the modulation transformer secondary.

This scheme is applicable to nearly any small rig, and I have successfully employed cathode keying of a 5894 on 2 meters and an 829 on 6 meters. To put any other rig on CW, it is necessary only to open the final cathode circuit and install a key jack, and short the modulation transformer secondary. If the modulation transformer isn't shorted you probably will end up with a second-rate CW signal, and may be forced to purchase a new modulation transformer, modulator tubes, final, etc. Remember Lenz's Law! It isn't necessary to disable the modulator, but it does cut power consumption and is a bit more professional. This may be accomplished in many ways; opening the cathode, breaking the plate and screen circuits, opening the screen lead, etc. If your power supply has very good regulation, you may dispense with the VR tube, but it's cheap insurance against a poor signal.

This technique has been successfully applied to the Tecraft 220 transmitter and a 6360, 220 rig similar to the rig in the ARRL Handbook of a few years ago. Give it a try, get on VHF CW, and join the Great Society!

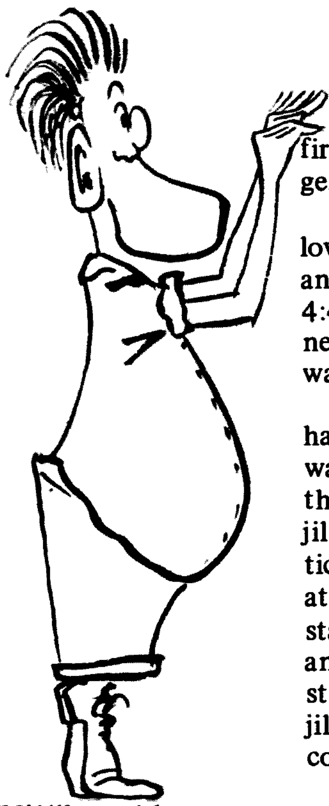
Mondo Hamme

Bob Manning, K1YSD
915 Washington Road
P. O. Box 66
West Rye, New Hampshire 03891



"OH NO! NOT AGAIN!!!" – with a nauseating SSSHHHHGGLLOPP!!! one sixth – or roughly one hefty handful – of a Sara Lee chocolate meringue cream pie whizzzed past my head and came to rest on my sound absorbent wall-covering, in the process, my T/R switch a new RCC certificate and an autographed 8 X 10 glossy of my hero, J. Croyden Seymour. [Poor ole J. Croyden! He was instrumental in interesting me in amateur radio and assisted in the planning of my ham shack. Regretably, he was prevented from seeing the completion process – having been struck down in one of the most bizarre accidents in homo sapien history.

It seems that a jilted young lover, who lived nearby, had decided to do away with himself by swallowing something toxic, then speeding to the home of his unrequited love, dramatically expiring on her door step. Unfortunately, he arbitrarily grabbed the first bottle in the medicine chest and ingested 2.9 litres of castor oil.

On the way to his destiny, the young lover was overcome by that 'irresistable urge" and, breaking all records for the Fat Man's 4:40, he sped into the men's room of the nearest gas station (appropriately enough, it was a "Flying 'A' " station).

At that precise moment in time, the hapless J. Croyden, an extremely frugal man, was attempting to climb under the door of the only vacant pay stall in the place. The jilted lover plunged headlong for that particular door, deposited his dime and attempted to gain entry. Since he was standing on J. Croyden's spine and the door and floor were making rapid and repeated staccato contacts with J. Croyden's head, the jilted lover couldn't get in and J. Croyden couldn't get up.

The jilted lover, loudly bemoaning his fate, was doing what appeared to be a combination "War" "Rain" and "Put out that damned fire" dance all over J. Croyden's prostrate form. J. Croyden, being alternately pounded on the jawbone by the floor and the cerebellum by the metalic door was gurgling, "I'll pay – I'll pay – dammit I'll pay!"

Within a very short span of time, some other highly predictable events took place – none of which are relevant to the story save that they left J. Croyden with some odd residual inhibitions.

Since that day, his spare time is spent wandering around town with a harried look on his face, putting coins into pay phones, parking meters and gum ball machines, keeping up a continual mumble of "Ya can't beat 'em! ya gotta pay! – ya just gotta pay!!"

At one time, unable to find a coin slot, J. Croyden just up and swallowed a fistful of coins – he lay in a hospital bed for three

days before there was any change.

J. Croyden's family tries to keep him home as much as possible – not only to save money – but because every time J. Croyden hears unexpected running footsteps behind him, the Fire Department must invariably be called to rescue him from the top of the nearest telephone pole, street sign or some precarious window ledge.]

All this flashed through my mind as I watched the artificially colored meringue oozing, like some science fiction glob, onto my SWR bridge, Vibroflex and G. E. Clock/Timer. I knew, with that instinctive inborn canniness of the long-married ham, that I – through my interest in amateur radio – had somehow irked my wife. Had I forgotten to take out the garbage? Overlooked an anniversary? Forgotten our 12-year-old kid's – whozzis's – name?

I didn't turn my head – uh uh – oh no! The last time I did that, I kept right on talking and brought my D-104 along with me. The second salvo consisted of a 2-week-old bagle which made forceful and direct contact with the D-104 – driving it and my partial plate half way to my esophagus. It took an hour and a half to get pieces of the D-104 out of my teeth and another hour to get pieces of my teeth out of the D-104.

"Sweetheart," I said, "I wish you'd correct for windage – that's the third clock you've hit since Newton Minnow's birthday. The clerk at the Radio Shop almost called the 'foam rubber taxi' the last time I asked for a 'meringue-proof' clock!"

"RAAWWKKKK!!!!!" screamed my wife – or some close approximation thereof – and another fragment of Sara Lee's epicurean delight found a spot dangerously close to the intake vent of the Air Conditioner.

"You never take me anywhere!" shrieked the distaff side.

"I do too!" I expertly reparte'd. "Why only last year I took you to the 'Anti lockjaw and Tongue Wagger's combination picnic, convention and orgy.' "

"Oh Shhure, you take me to those alphabet soup affairs. 'You're the ho hum' – 'how are the harmonicas?' and 'so you're YSD's XYZ?' "

"You got it all wrong, dear; I'm the O. M. – the kids are the harmonics and you're the XYL – L, not Z," I calmy replied.

"RAAAAWWWWWKKKK!!!! Ho hum – O. M. – harmonicas – harmon-

ics – XYL, XYZ, ABC, CBS, PDQ, who knows who cares! I feel like I'm at the Podunk Valley grammar school refereeing the semi-finals of a Sanskrit spelling bee – I I WANNA GO MEET PEOPLE WHO SPEAK WHOLE WORDS!!!!"

"Okay," sez I, "How about the night I took you to Howard Johnson's for dinner and cocktails?"

ZIPPLINGGG! – the empty pie plate caromed off my hand key, ricochetted into my message blank file and came to rest, face down, atop the head of our jittery, goggle-eyed poodle, who took off like a hairy hippie midget – a little more jittery and definitely more goggle eyed.

"Howard Johnson's! Howard Johnson's! *Howard Johnson's* – what a night that was. All the way there and all the way back you kept hollering into that junk you got stuck under the dashboard – 'I'm mobile – I'm mobile' – you got so much stuff under the dashboard that I have to ride in the back seat. . . . "

"But lover, you keep kicking holes in my speaker. . . . "

"I'll kick holes in your head, you cuckoo!!! and another thing – If you say, "I'm running mobile in the car tonight with a *hustler* one more time boy and. . . . "

"But dear," I said, "that's the name of the antenna."

"Antenna smantenna! Just one more time and you'll be talking to a divorce lawyer with a carved 'Z' on your forehead and that stupid antenna hangin' out of your navel!"

Drawing another breath, she said, "Do you remember what happened when we got to Howard Johnson's? I'll tell ya – you inhaled two martinis, tap tapp tapped your way through half the meal with your swizzle sticks then commandeered the paging system microphone and called CQ into a crowded

restaurant and made two contacts – one, a nearsighted insurance salesman who spent a goodly part of the evening trying to sell policies alternatively to a hat rack, the juke box and the post card rotisserie; and the other was an itinerant 'dirty book' salesman – (you sure he had mobile gear in his trunk?) Anyway, you spent the rest of the evening talking alphabet soup at the table.

"Why, we can't even have people over for an evening!"

"That's not so darlin'. We had the Carsons over just two weeks ago." I retorted, slyly trying to slip my son's whatziz name's football helmet over my head and earphones.

"That was another terrific evening," my wife blurted. "First, as they came through the door you started off with 'hi there, you've met my Wife, *W*hiskey, *I*ndia, *F*oxtrot, *E*cho, Wife and my oldest daughter, Linda, *L*ima, *I*ndia, *N*ovember, *D*elta, *A*lpha, Linda haven't you?' Then we later tried to watch TV, but you got off on UHF, VHF and TVI – more alphabet soup – then Harry started telling jokes and you brought out an old electronics magazine, opened to a dog-eared page and sat there roaring for a full fifteen minutes at the title alone – I still don't see what's so funny about an article entitled, "HOW TO MOUNT AN OSCILLOSCOPE!"

"And you kept calling Harry a stupid 'top' all night!"

"That's *lid,* dear," I said.

"Top, cover, cap, lid whatever . . . did you have to throw him out of the house just 'cause he asked if you could pick up police calls on your ham rig?"

"It wasn't just that, honey – but when he asked, 'how far will this thing pick up?' I told him 'exactly half way around the world in any direction' and he didn't even chuckle!" sed I.

"I could even take this stuff on a part-time basis, Bob, but last night you phoned and said you wouldn't be home until a hundred and sixteen Swahili – I never know what the hell you're talking about. . . . "

"That's 'sixteen hundred *Zulu,* sweetheart' "

"Swahili, Zulu or Watusi – what the hey – they're all members of the Bantu Nation. How come you can't just say 'four o'clock'??"

I was saved at this point by the ringing of the door bell.

"Come in!," I yelled overly loud and a little hysterically. The door opened and J. Croyden ambled into the shack and, with a 'clunk', deposited a nickel into the piggy bank we had installed just inside the door for just that purpose. "Ya gotta pay old son," said J. Croyden, and began to survey the shack as my wife headed for the kitchen.

Noticing the Sara Lee ingredients dripping on, over and around various pieces of equipment, he said, "Well, either someone sent you a chocolate parfait time bomb or you been having troubles with the XYL again."

"No initials puuuleeease!! I'm in enough trouble already, J. Croyden!"

"Sorry, son." 'clunk', another nickel . . . "what started if off?"

"Well," I said, wiping chocolate goo out of a phone jack – "I guess I forgot an anniversary – or I haven't been paying enough attention to the wife – or some foolish thing like that – last year it was because she wanted a 'second' dress!"

"Tough" said J. Croyden – searching for another coin – finding none, he wrote out an I. O. U. and stuck *it* into the piggy bank.

"I suppose it all started when my Mother-in-law was here. She looked up at my tower and tri-bander and asked what it was – so I told her it was a clothesline for the Jolly Green Giant – Ya know what I wish, J. Croyden? What I really really wish??

"Whazzat??"

"I wish to hell I had a way of ending this article – thats what I wish!"

"There is no end, old son," said J. Croyden "It's a vignette!"

"MONDO HAMME – IT'S A HAMS LIFE. . . . "

...K1YSD

Convention Hotel Burns

On May 9th, exactly two weeks before the New England ARRL Convention in Swampscott, just as all of the final details had finally been ironed out by the convention committee, the New Ocean House Hotel managed, with the help of a weak water supply from the town, to burn to the ground. Some very fast footwork on the part of the committee resulted in their obtaining the Statler-Hilton as an alternate. The convention will come off on the same days as planned, but in downtown Boston instead of out at Swampscott.

Straightforward SSB for 6 Meters

Murray Ronald, VE4RE
Box 947
Brandon, Manitoba
Canada

There have been many different circuits put forward over the years for getting an SSB signal on 6 meters. They range from the simple transverter to the full-fledged single band affair. This little unit was intended mainly for field day or portable use; however, it now forms the backbone for my station, being used directly on 6 meters and with transverters on 144 and 432 MHz. It was designed to be simple yet effective; thus the PTT and single conversion with option of spot frequency injection or VXO. The 2E26 final provides about 30 watts PEP input; however, substitution of a 6146 with suitable changes in power supply voltages would almost triple the power input.

L1–30T 28 e. on 3/8" form. Link 2T of hookup wire at center.
L2–12T 18 tinned airwound, 3/4" O.D., 1 1/8" long. Link 2T hookup wire at center.
L3–15T 28 e. on 5/16" form. Link 1T hookup wire at "cold" end.

Table 1—Data on coils and special components.

The Circuit

The block diagram of **Fig. 1** illustrates the overall layout of the exciter. The 7360 oscillator balanced modulator is a conventional circuit in which the cathode, grid and screen form the oscillator circuit while the plates and deflection electrodes are utilized in the balanced modulator circuitry. The DSB signal produced in the 7360 tank circuit is passed through the 9 MHz filter at which point one of the sidebands is removed. After amplification in the 6AU6 *if* amplifier, the 9 MHz SSB energy is applied to the 7360 balanced mixer. 41 MHz energy fed to the grid of the 7360 mixer is cancelled out in its tank circuit. The 5 pF butterfly capacitor is brought to the front panel as the "mixer tune" control. CW operation is provided through cathode keying of the mixer stage and has proved to be quite satisfactory.

The 12BY7 functions as a straight-through class A amplifier whose plate circuit trimmer appears on the front panel as the "driver tune" control. Link coupling to the grid of the 2E26 is used to further attenuate any undesired feedthrough. Neutralization of the 12BY7 was not found necessary because of careful shielding across the tube socket below the chassis. With suitable pin connection changes, a 6CL6 would serve as a good substitute for the 12BY7. The 2E26 final operates in class AB_1 in a conventional circuit employing capacitive neutralization.

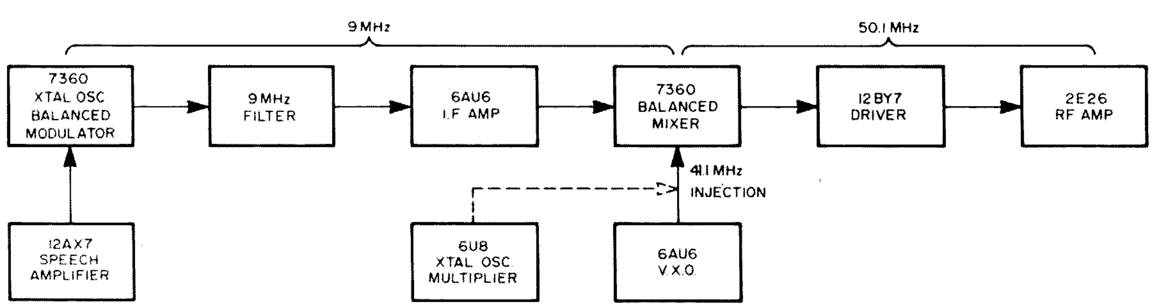

Fig. 1. Block diagram of the *rf* section. Single conversion path is illustrated.

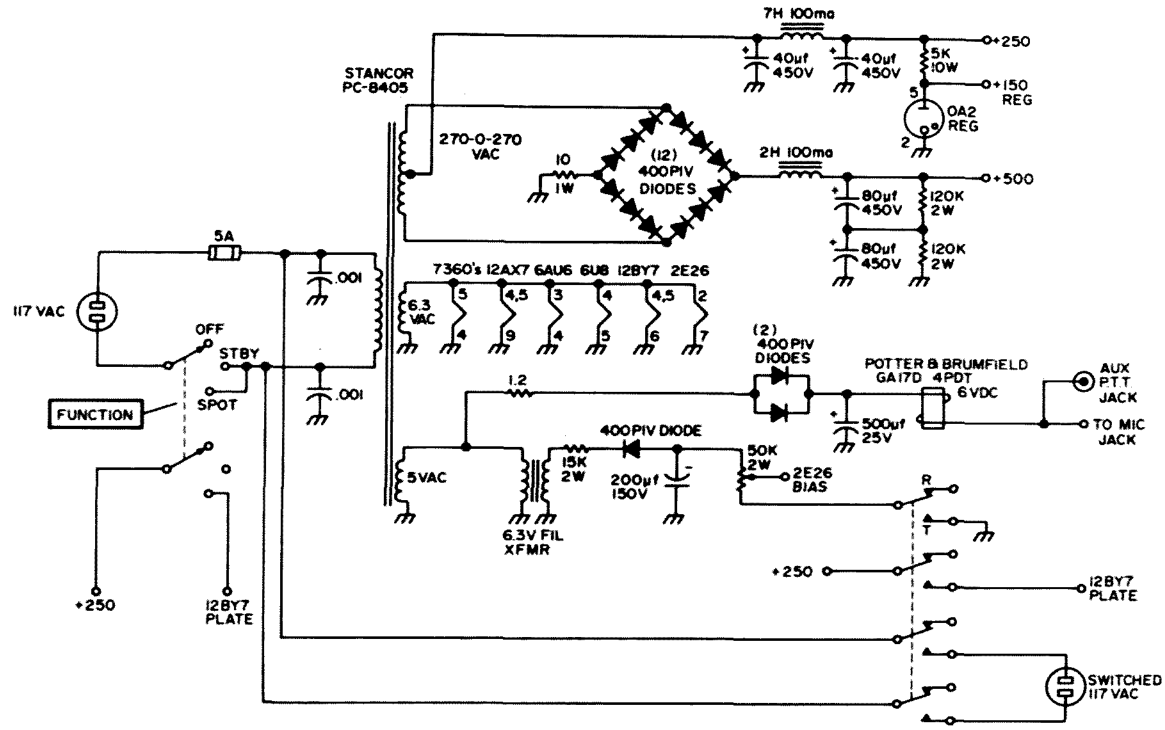

Fig. 2. Power supply and control circuitry. The controls, which are brought to the front panel, are shown in boxes.

Power Supply And Control Circuits

The power supply (**Fig.** 2) may consist of any common "TV" type transformer functioning in a dual voltage arrangement; the final's plate voltage being provided by bridge rectification, and the lower plate voltage by full-wave rectification through two legs of the bridge. Bias voltage for the final amplifier is derived from a reverse-connected 6 volt filament transformer connected to the used 5 volt filament winding of the power transformer. Transmit operation is provided by grounding of the floating side of the 6 volt dc relay. This may be accomplished with a push-to-talk microphone or by an auxiliary "transmit" switch. When not transmitting, plate voltage is removed from the 12BY7 to allow it to run cooler. The 2E26 bias is increased during standby by ungrounding one end of the bias adjust potentiometer.

Construction

Considerable thought went into the layout of this transmitter. Since the components are standard, builders may duplicate the layout if they wish. As detailed in **Fig.** 3, the 7360 sideband generator and the 12AX7 speech amplifier are located next to the front panel. Consequently the three controls and the jack associated with these stages can be mounted directly on the front panel without excessive lead length. The main chassis was assembled from aluminum, while the shielding was cut from thin brass sheet. As illustrated in the photographs, brass or copper partitions are placed across the *if* amplifier, mixer and driver tube sockets. All ground connections can be made directly to these partitions eliminating the need for ground lugs. Two of the partitions also serve as mounting for the mixer and driver tune controls. The 2E26 final is completely enclosed in a compartment at the rear of the chassis. A suitable enclosure can

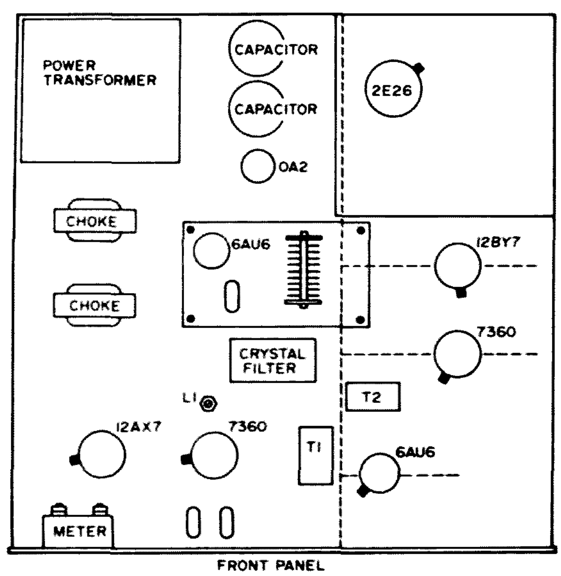

Fig. 3. Component layout viewed from above. Dashed lines indicate partition placement below chassis. The tab at each socket indicates position of pin 1.

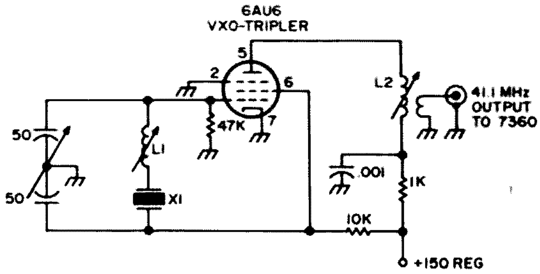

Fig. 4. Schematic diagram of the vxo tripler.

often be salvaged from the high voltage "cage" of older style TV receivers. Extensions to the front panel for the mixer, driver and final amplifier controls were made from ¼ inch brass tubing. Short lengths of tight-fitting rubber tubing were used to couple the extensions to the capacitor shafts.

There are two small subassemblies used in the construction. The bridge rectifier diodes are assembled on a phenolic board which is bolted vertically underneath the chassis. Small holes are drilled in the board; the leads of adjacent diodes are placed through a hole, bent over, clipped, and then soldered together. If desired, 270 K resistors and .002 disk ceramics may be paralleled with the diodes to give voltage equalization and transient protection. The components associated with the rf output meter are mounted on a terminal strip which is bolted inside the 2E26 compartment near the antenna jack. A shielded lead carries the rectified voltage to the meter on the panel.

The 41.1 MHz injection is supplied by a VXO assembly built on a small plate and mounted above the main chassis. Certain of the VXO components such as the crystal socket and tuning capacitor are mounted ¼ to ½ inch from the plate to minimize capacitance to ground.

The usual VHF wiring techniques must be observed in order to produce stable TVI-free operation. All filament leads should be shielded and .001 disk ceramics should be placed from the hot filament lead to ground at each tube socket. In the higher frequency rf stages, lead length should be kept short. Grounding should be done as directly as possible and it is desirable to have only one or two common ground points for each stage. All plate voltage leads to the mixer, driver, and final, are routed through the main partition with feed-through capacitors.

Special Components

The 10.7 MHz *if* transformers used in the 6AU6 amplifier, are an older style of transformer using slug-tuned windings. They are more easily adapted than the smaller "K-Tran" type. In T_1 the primary winding was removed and replaced with a 3 turn link. The secondary of T_1 is moved down to 9 MHz by the addition of a mica capacitor. In

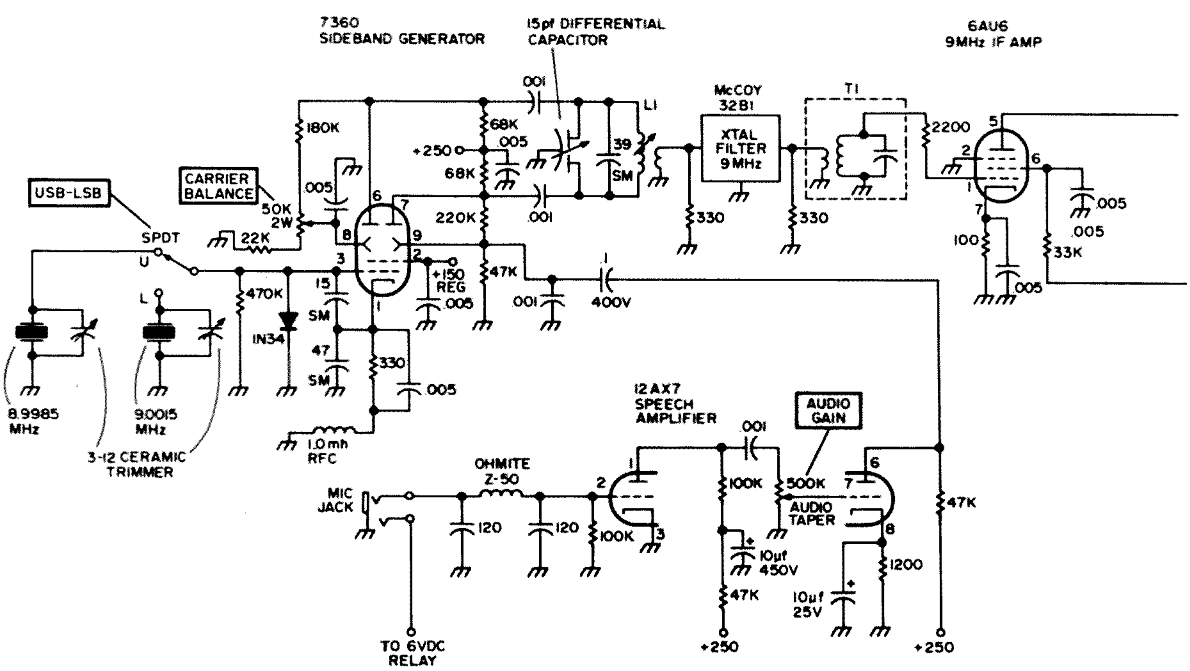

Fig. 6. Circuitry of 50 mhz exciter. Controls brought to the front panel are shown in boxes.

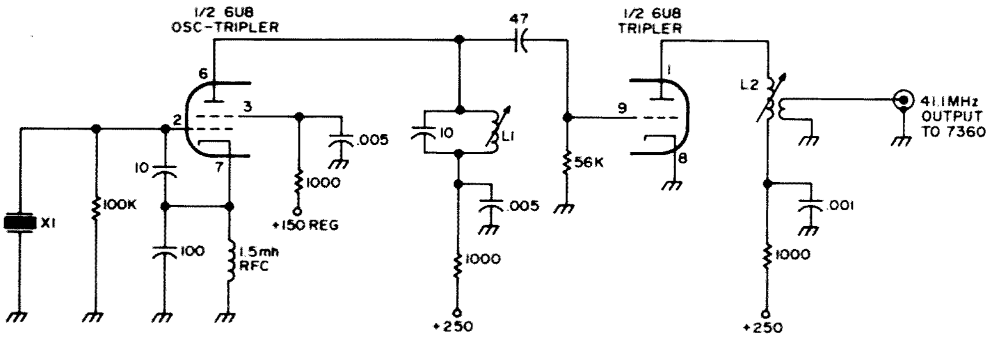

Fig. 5. Diagram for the oscillator tripler.

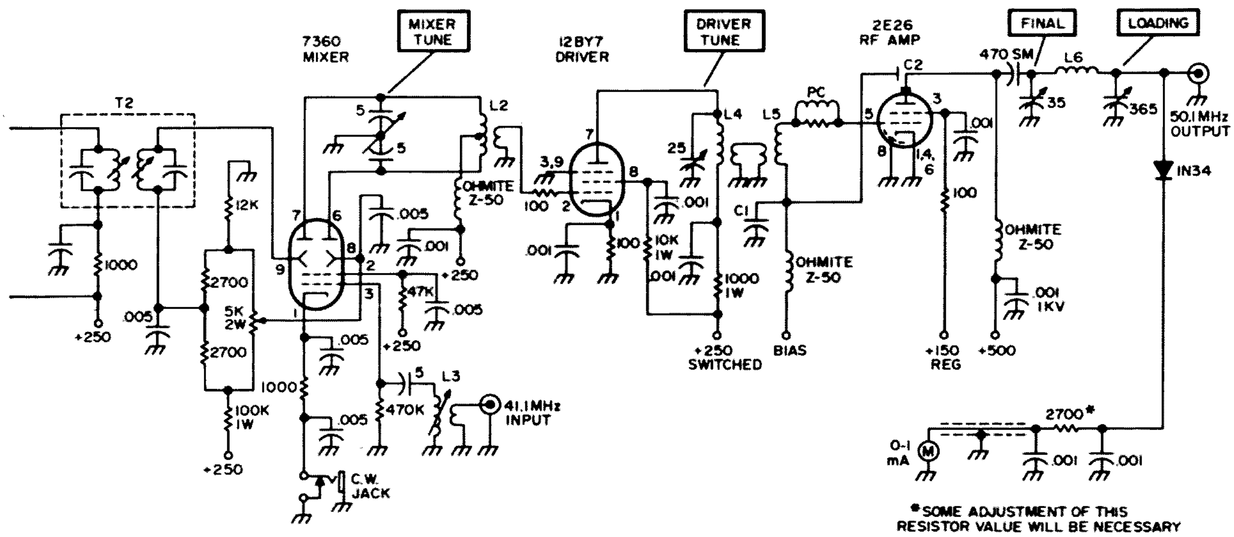
a similar fashion the primary and secondary of T_2 are lowered in frequency.

Some will argue that L_1 should be bifilar wound. Both a conventional and bifilar winding were tried and no significant difference in carrier suppression was noted. The differential capacitor associated with L_1 was constructed by taking a regular air trimmer, setting its rotor at half mesh and after inserting cardboard wedges between the stator plates, cutting through the stator with a fine toothed hacksaw blade. Of course this capacitor is available as a regular item if you can get your hands on one.

The 2E26 final is stabilized with capacitive neutralization. Capacitor C_1 should be mica and will be in the 330 to 560 pF range while C_2 is simply a stiff wire passed up through the chassis into the final amplifier compartment and placed near the tube plate.

Tuneup and Adjustment

It is assumed that the constructor will have checked all coils for approximate resonance (with the tubes in their sockets incidentally). Applying line voltage and setting the function switch in the standby position will place plate voltage on all stages up to the 12BY7 driver. A VTVM with an rf probe is almost mandatory for tuneup. Place the rf probe at the 6AU6 grid pin and adjust the carrier balance control to secure a reading. With the differential capacitor set at center adjust L_1 and T_1 for a peak reading. The differential capacitor is then adjust-



ed for a null. Set the ceramic trimmers across the carrier oscillator crystals at minimum setting and while switching from USB and LSB positions check to see that the VTVM reading remains about the same. This indicates that the crystals are centered reasonably well on the filter curve. Proceeding next to the 7360 mixer, place the probe on pin 9 and adjust both windings of T_2 for a maximum reading. Then with 41.1 MHz energy applied check pin 3 for a reading. It should be about 1 volt with L_3 adjusted to resonance. The next step is to remove the 6AU6 *if* tube to prevent 9 MHz energy from reaching the 7360. With the probe at the center-tap of L_2 adjust the 5K 2w potentiometer for minimum 41.1 MHz feedthrough.

Apply voltage to the 12BY7 with a temporary jumper and with the probe at pin 5 of the 2E26, peak L_2 and L_4 and adjust L_5 by the "squeeze" method. Moving the probe to the plate of the 2E26 adjust C_1 and/or C_2 for minimum feedthrough of 50 MHz signal.

A fairly satisfactory alignment of the carrier oscillator crystals can be accomplished as follows: with the rf probe at pin 9 of the 7360 mixer and with some carrier inserted increase capacity across the 9.0015 MHz crystal in order to move it down into the filter passband. Note the VTVM reading and then adjust the trimmer to yield a reading approximately three-quarters of the "passband" reading. Set the 8.9985 MHz trimmer to give a similar reading.

Afterthoughts

Some builders will wish to modify some of the circuitry to fit their likings and their junk boxes. One improvement would be a four position function switch to allow for a "manual" operate position. In the control section, by use of the negative bias voltage to disable the low-level rf stages one could use a relay with fewer contacts. Furthermore, only one side of the ac line need be opened for the switched 117 VAC.

The idea of tripling in the VXO tube was suggested by W2ALL and has proved very satisfactory. VXO shift was held to approximately 40 kHz to give maximum stability, but with more series inductance coverage of 100 kHz should be possible with good stability.

Building the exciter consumed quite a few hours of my spare time, but I enjoyed it, and am looking forward to building a transistorized version in the future.

The 432'er, Solid State

William F. Hoisington, K1CLL
Far Over Farm
Peterborough, New Hampshire 03458

This is a low-cost, all-solid state, A.M. rig complete with superhet receiver, to explore the possibilities of the entire 420 to 450 mhz band, to use in a car, boat, camping, on mountain tops, even the *walk-up* ones, and to have fun with.

You cannot use it to talk to the lads with narrow-band *if* sets clustered around 432 mhz, until you add the crystal controlled oscillator-exciter later. The *rf* amplifier is right there ready to have the crystal job plugged into it, but for the moment it is a lot easier and quicker to plug in a simple oscillator. This is the famous MOPA (Master-oscillator-power-amplifier). It takes a receiver with a bandwidth of several tens of khz, like the Gonset Communicator Three, to receive an MOPA signal on the 420 to 450 megacycle band, but just wait and see what you do with rigs like these!

As soon as you do add the crystal part you can talk to those sharp boys on 432. Then if you plug in a narrow-band *if* (like 455 khz) and a crystal-controlled local oscillator as well, you will have the best. But, and it's a mighty big "BUT," you will then have to use some kind of a tunable *if* front end.

The 432'er solid state receiver

RF Stage. Like sticking your hand into a basket of snakes! Now, I've built plenty of six and two meter *rf* stages, with various transistors, and they worked fine. But, up around 432, things are different! I've made up tube *rf* stages, as in 73 Magazine, 1963-1964, oscillators galore, and assumed that the small signal *rf* stage would be duck soup. Nothing doing! As soon as I started to bring up the gain, using a tuned base input circuit, and tuned collector output, *oscillation*! The more I matched things, the more it oscillated. The trouble with transistors today is they're just too darn hot! Also, holding to the policy here of never writing up anything not actually on the air at the shack, one and a half full days went by on this item alone. The GE "Microtabs" worked. So did the 918s, the 2n3600 RCA units were good, the KMC 2n2502s gave fine gain but oscillated more, and the Fairchild MT1116 gave the greatest gain. For $40, they ought to.

Neutralization was tried. No good so far. Oh, I haven't given up on that by any means. It's just another challenge (the story of my life) to be taken up later.

I suspect the internal resistive feedback as well as the capacitive feedback to be causing the trouble. More later, I hope.

So, to get on with the actual circuit that does work well without oscillation, Fig. 1 shows the schematic. The input cable is matched, not perfectly but good enough, by CI, which gets to be pretty large because those base-emitter diodes have an amazingly low impedance as you go up in the hundreds of megahertz. I tried various kinds of strap and capacitors for pi networks into the base. Too susceptible to oscillation. Matched to the cable, but untuned, does the job. That little one K resistor from the base helps a lot also; partly dc-wise, into the bias network.

Table 1 shows some comparison gains with different transistors. An *rf* stage of this kind has two main purposes. A) To set the noise figure. B) To provide some gain and a

Table 1. RF stage gains with different transistors.

lot of freedom from image, spurious, and harmonic mixing. Not too many unwanted signals get past that half-inch copper strap!

Bear in mind that we are setting up here a "Gonset Communicator" type of rig, with a complete receiver and transmitter, and that you can expect to put in a real low-noise stage in front later to "set" the noise figure at some better and impossible-sounding figure like 1.7 db, or thereabouts. This will help you pull in that elusive guy you hear way down in the noise some evenings.

Also, more power can be added to the transmitter later. That takes a real stuffed pocketbook though. I hope to be able to help with this item later.

When you get past the base circuit, watch the variable emitter resistor. If you're really looking for good adjustment make it variable. I wound up with 100 ohms fixed which gives a little under 10 ma of current. In any case, you should provide a variable resistor for tune-up first, because almost every solid state device (trade name for transistor) varies from one to another, even with units of the same number and manufacturer.

For emitter by-pass, I used the old reliable brass plate, nylon bolt, and thin fiberglass insulation, about three mils thick. Keep the emitter lead as short as possible. The final length in this model was between one eighth and three sixteenths of an inch.

The collector circuit is of the strap-line type and not too critical, tapping the collector down on the strap is very beneficial as to gain freedom from oscillation, raising the Q, etc.

The circuit as shown in Fig. 1 shows mainly a large strap, and this is as it should be because the collector circuit is where the amplified power is to be found, and in this receiver with just one *rf* stage, at least to start with, we used a strap to get all the Q and filtering possible.

Fig. 2 shows the *rf* input side view with the input jack on the rear panel of the minibox. Once again, I use "phono-jacks" because they work. Use the ones with the ceramic insulation. Or "BNC" types if you like. A copper clad base board is bolted to the bottom of the

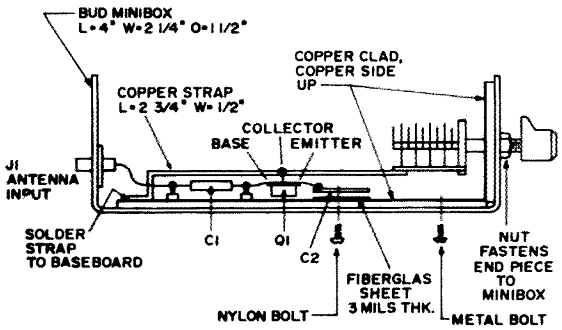

Fig. 2. Side view, *rf* stage.

minibox simply for convenience in soldering grounds, etc.

Fig. 3 is a top view which I hope is nearly self-explanatory. Fig. 4 likewise. C3 can be used to fasten the copper clad end piece to one end of the minibox.

Dimensions are shown in Fig. 3, adjusted to fit into a minibox, making a complete self-contained unit with input and output jacks. As mentioned in the main preamble on the 432'er, a "Rack and Panel" type of carrier is used, but small in size, made of wood, with aluminum paint sprayed on. It is very flex-

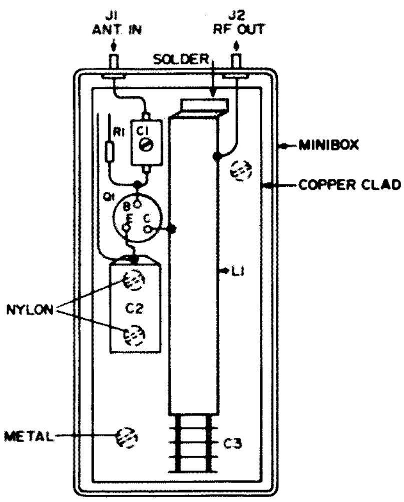

Fig. 3. Top view *rf* stage, 432 m.c.

ible to use, as you can fix the units on shelves, or use the sides like a rack.

It has a handle of dowel wood on top, antenna on the side, lantern batteries with six watts dc capability on the lowest shelf along with the *af* and loudspeaker, *af* amplifier-modulator next, then the transmitter, *if* near

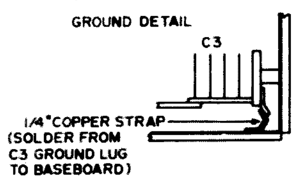

Fig. 4. Ground detail.

the top, and *rf* head on the top shelf. Everything comes out at a moment's notice for adjustment, change or repair, and the whole deal has considerable "growth possibilities built-in" as they say on Madison Avenue. So you can add an extreme low-noise *rf* stage, change to or add a narrow-band *if* strip, etc, etc. Don't say I didn't warn you!

Power supply for the *rf* stage is twelve volts at ten milliamps or less, depending on where you set the emitter resistor. It also works well on one of those nine volt transistor batteries. I intend to standardize on the lantern-type batteries from now on. Union Carbide rates theirs at half an ampere maxi-

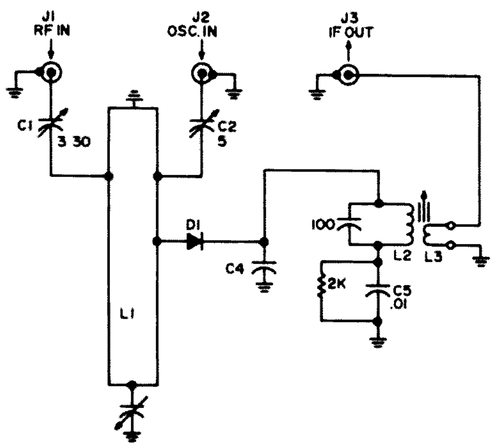

Fig. 5. Schematic, mixer, 432 m.c.

Parts List

CI = 3-30 trimmer.
C2 = Ceramic Trimmer (about 5 pf maximum) (ARCO 400).
C3 = Johnson Type M, 9 plate.
C4 = Brass plate capacitor.
D1 = Good uhf diode.

mum, which is six watts of dc power, with two of them at twelve volts, which is about all you can easily carry up some of those good DX mountains by hand.

There are some intriguing new small non-spillable storage batteries out also, which will go for more watts, later on. Twleve watts dc seems to have good possibilities to me though.

Using a combination regenerative single transistor in an oscillator-dipper-detector circuit, I have pulled in and identified all five Massachusetts UHF TV stations between 500 and 600 mhz from here in Peterborough, N.H., using just the tuned circuit on the bench as an antenna. For security, tune up and check the mixer circuit with just a dc meter (see **Fig. 10**), and even then watch out. In Melrose, Mass., the Malden TV station is about 3 to 4 miles away and would move a meter from a single diode on the bench! Don't forget, those lads put out hundreds of *kilowatts* ERP.

Connecting everything up, the meter went off scale as soon as I hit 432 mhz with C1. Things got even better as the minibox cover was put on and the output went up a little. A high Q fully enclosed signal circuit is nice, because don't forget, you're going to follow it with a high gain *if* amplifier which will pull in signals of less than a microvolt. And these signals should be your new contact from across the state, not from the TV station in town. Those Bud Miniboxes are not perfect of course. Some more self-tapping screws around the edges will help to seal unwanted *rf* out and cut down on noise that can be caused by slight motion of an improperly sealed cover.

With the dimensions given, 432 comes close to the middle of the dial. Don't forget, we want to tune our whole band of 420 to 450. After all it's still ours! Yet!

The six megacycle *if* output coil is next, and a painless method of getting this inductance right, which also serves to make up the *if* coils, is detailed next. (Skip this if you're sure you know how already). There are several ways to do this but in any case the final result is "on the air" so we'll start that way and arrive quicker.

The 432 mixer

There should be no problems here. We already have a good strap line circuit that tunes below 420 and over 450 mhz and fits in a small minibox, so all we need after that is an oscillator input, a good diode and diode by-pass for 432, a tuned circuit for the *if* output on six mhz, a diode bias resistor and capacitor, and an output coupling and jack. See how simple it is?

Fig. 5 shows the schematic and **Fig. 6** the

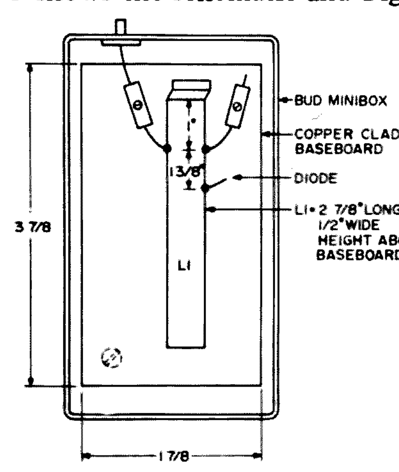

Fig. 6. Dimensions, Mixer, 432 m.c.

dimensions, which match the *rf* amplifier. With luck the oscillator will go into the same size box (it did) and we will have three small matching boxes for the *rf* head.

I have shown a dc lead (temporary) from the diode by-pass capacitor plate, C4 to J3, because this allows a fine check on the *rf* mixer section. A modulated 432 test oscillator is fed through a coax cable to the input jack and *rf* tuning and dc voltage out of the diode, with Minibox cover on and off. This is important because of oscillator harmonic mixing. This little devil has ruined many an otherwise fine home-brew project, so you'd better be aware of it. It shows up most, on six and two meters, when you start tuning up converters on the bench. That's partly what all the thousand screen rooms throughout the USA are for! Your mixer is there on the bench, no shielding (yet) and FM, VHF TV, and UHF TV all come boiling in. You're probably using a high gain *if*, most likely 455 khz. sharp, (doesn't like FM!) and of course, what with many oscillator harmonics and many TV and FM stations, you've had it! Harmonic mixing has been used, and described in the good old RCA 1500 page "Bible" on how to build receivers. The many harmonics simply act like local oscillators on higher

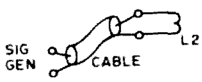

Fig. 7. Coil test set-up.

frequencies to produce, at times, a tremendous set of nuisance signals.

Fig. 7 (coil test set-up) shows how to do it in a real painless fashion. Connect your signal generator (the $30 Lafayette job is fine) through an *rf* cable to L2, solder coil leads to test terminals T1 and T2, connect a "diode plank" (Fig. 8—you *must* have one of *those*!) a microammeter, and go. I found 35 turns of No. 34 enamel, on about 3/8" diameter coil form to do the trick, with an 8/32 threaded powdered iron slug inserted for tuning. With 100 pf across the coil it tunes from 7.5 to 4.5 mhz reaching the desired 6 mhz with the slug about half way in. You can have lots of fun checking coils, Q, and slugs this way but, get on with the 432'er!

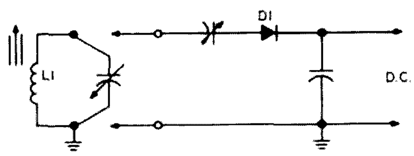

Fig. 8. "Diode plank."

Fig. 9 shows the mixer output circuit details, with two small standoff terminals holding the coil wires and C2. L3 is three turns of insulated No. 24 or 26 wound around the cold end of L2, and waxed in place with coil wax. Don't forget, all these special components you may not have on hand may be obtained in kit form (see end of article).

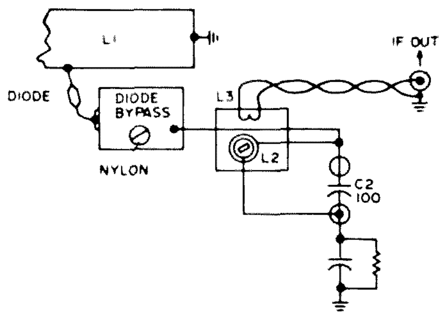

Fig. 9. Mixer output circuit details.

Have just finished assembling the mixer output circuit in the minibox and it may be tough for older eyes and fingers. But if I can do it, you should be able to also; being 64 myself right now. Of course, I've done this sort of work for many years (about 45!) and have two sets of eyeglasses, one about one and a half times magnification, the other about two times, for those really tight little spots.

Testing the mixer into a tuned *if* circuit without amplification is not an absolute necessity but sure helps as a check on the mixer conversion efficiency and getting good tuning out of the output coil. When you have a high-powered *if* running with avc it is sometimes hard to notice small differences in gain or selectivity, which can all add up, or down, together on those weak signals to come. With only a 6 mhz circuit and diode after the mixer, you *have* to get everything right such as the *rf* input, the 432 megacycle tuned circuit, the diode, its bypass, the 6 mhz diode output coil, and its output coupling. **Fig. 10** shows a test circuit good for this sort of work, with both dc and *af* outputs. Simple as ABC, useful as a pocket in a shirt and yet you still have to build it or buy a grid-dipper. If you're really going in for home-brewing, you'll need a whole slew of these covering all frequencies!

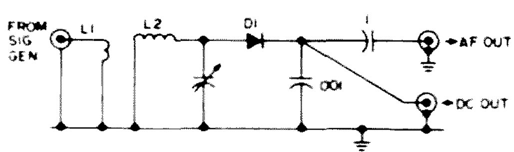

Fig. 10. Tuned diode detector with d.c. and af.

When the mixer was set up, a local oscillator and a signal generator plugged in, the *if* plugged "out," conversion to 6 mhz was soon obtained through the diode, and all circuits were peaked up. I also tried my big receiver on it and picked up the crystal controlled signal generator from way out in the field, but the non-crystal controlled L.O. was of course too jumpy for this type of operation. Check back in the first section for this item just in case you don't remember about narrow-band receivers as *if's* for tunable local oscillators on UHF.

RF local oscillator

I could breeze through this at top speed, but always there are new listeners, (there'd better be!) so skip parts you already know. After completing the assembly and tune-up I've changed my opinion. Don't skip it! With thoughts in mind of later ganging the three units (*rf* amplifier, mixer, and oscillator) this unit was made with the same baseboard, strap, and type M capacitor. Instead of the emitter being grounded as in the *rf* stage, the base is grounded putting it out of phase with the collector. This automatically makes it an oscillator except in certain extreme cases.

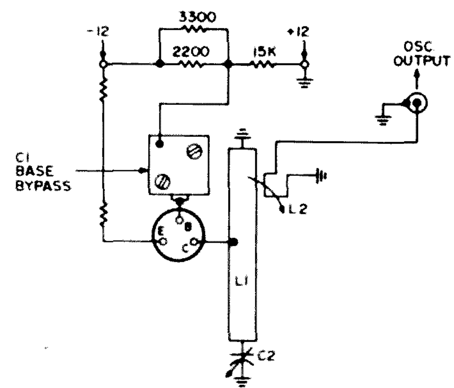

Fig. 11A. Oscillator schematic.

See **Fig. 11** (schematic) and **Fig. 11B** (dimensions). Among the things you want in a tunable *rf* local oscillator are stability and freedom from pulling, that is, as much as you can get...So, run a fair amount of power and decouple as much as possible into the mixer. Above all, have a *good* oscillator. This one worked immediately and why not? Anyone can build an oscillator, can't he? (Sometimes I can't myself. See later). I took two plates off the nine plate Johnson type "M" capacitor to put 432 in the middle of the dial, checked out the total emitter resistor needed, with an outboard pot., and that's it. Except, there were some nasty little spurious signals tuning faster than "regular" signals. These

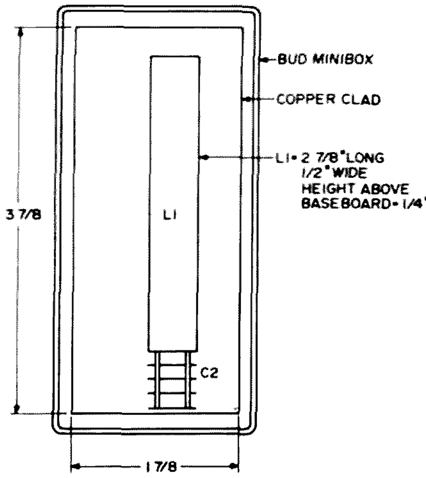

Fig. 11B. Oscillator dimensions.

little hitchhikers come in without an antenna too, which is *real* bad. Remembering the old days of a high grid leak (never mind what that was, just read on!) the base resistor was cut down a little, from 2,000 ohms to about 1,800 ohms, and the spurious vanished. I later changed the cable and coupling to the mixer and put back the 2,000 ohm resistor. In case you get this type of spurious (there are others) that base resistor is the first place to check.

The 6 mhz *if* amplifier

There is nothing too special about this unit, other than considerations of bandwidth, image, gain, freedom from oscillation, reproducability (to allow any amateur to build one), why you can't use a well-known *if* strip using 455 khz for under $5, proper avc, good *af* out, 6 mhz output tap for a low-frequency converter and narrow-band *if*, and, last but by no means least, low cost.

Going through the listed considerations in order we have: A) Bandwidth. I picked 6 mhz for the *if* frequency, giving a bandwidth of some 200 khz. I did this mainly because of my fondness for the way my good old Gonset Three acted, but it works out about right. If the bandwidth was any less, you'd have to use crystal control, if it was much more you'd begin to lose signals in the increased noise of the *if*. Of course, there are other ways to get bandwidth, like swamping resistors on the tuned circuits, etc., but this requires more stages for equal over-all gain. And, if you're going to run a narrow-band *if* after this one, you will not need *more* stages but less, at 6 mhz. You can see right now that even a "simple" *if* can get involved. We'll try and keep it short.

B) Image. At 6 mhz the image is 12 mhz away, and with two tuned circuits of half inch copper it may be enough. (It was.)

C) Gain. Three stages should carry us well into the noise region which is all the gain you need for this set. It did. D) Freedom from oscillation. Neutralization was not needed, but shielding was used. Small copper clad "walls" were installed close to the base lead of each stage, with a 3/8" hole for the base lead to go through, and this did the trick.

E) Reproducibility. This is achieved by making up coils that are easy to copy, giving detailed descriptions of how to build and test them, and laying out all components for easy checking and changing if needed.

F) You can't use a narrow-band 455 khz *if* strip with this receiver because it uses a tuned oscillator from 426 to 456 mhz, which cannot be stable enough (and low cost as well) to convert UHF signals into a low frequency, 10 khz bandwidth *if.* Later on, if you use a crystal-controlled oscillator you *can.* Again, this rig is planned to be easy to build, flexible for change and improvement, to be used along with a simple MOPA transmitter, to have fun with, mobile, hand-carried, for work across town, and who knows how far when you get two of them running. It's up to you if you add the crystal control, both in the receiver and in the transmitter. They will be described later. Don't forget that with crystal control in the receiver you will have to tune something else! And, if that something is an ac operated communication receiver, how are you going to carry it all around those mountain tops? Just a reminder.

G) AVC. This isn't too hard but there is a combination which has to be just right, so that the base bias does not put the diode detector into the wrong dc condition. All sorts of additional circuits can be used but this is planned to be an *easy* rig. So just wire it up as shown, it works well and so does the S meter which can be a simple one milliamp meter shunted down a little to read the second stage emitter current at nearly full scale. It works backwards but who cares. You can peak up beam directions and *rf* stages with it fine. H) Good audio output. This is the easiest. Just use a good diode with the right value of resistor and capacitor, plus almost any of the little Lafayette *af* amplifiers. J) The 6 mhz output is even easier. Just a link around the last stage inductor out to a jack, to be used later (perhaps) with a second mixer and narrow *if.* K) Low cost. If you already have a flock of VHF transistors that work at least at 6 mhz, some small coil forms and slugs, input and output connectors, a plank or two of copper-clad, a few capacitors and resistors, that's it. It won't cost you anything then, except maybe some of your days, and some cerebration.

Building and testing as you go

Fig. 12 shows the first *if* stage. It has lots of gain. With an antenna plugged into it, it pulls in London, etc., on the 6 mhz "short wave band." You can use almost any coil form you want because six megs is not critical but you must be sure it is tuned right. I

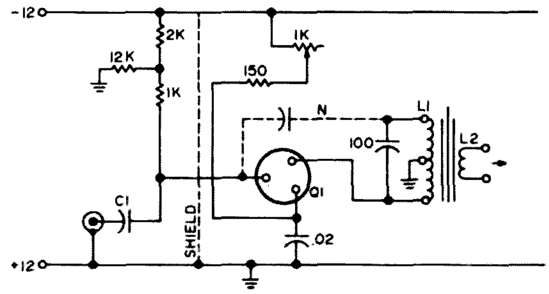

Fig. 12. First *if* stage, 6 m.c.

Parts List

L1 = 2 pi, 20 turns each, no. 30, with 6/32 threaded core.
L2 = 3 turns wound on center of L1.
N = neutralization not used. (Might be needed with other transistors.)

found the gain of the first stage to be up near 40 db with almost any of the good VHF transistors like 2n1726 and so on. It showed no sign of needing neutralization as yet so that part of the circuit is put in as a dotted line. Coil forms can be fixed iron core with leads and a ceramic trimmer, which will take a little more space; commercially available ceramic forms with movable iron core; very low cost phenolic tubing which is supposed to thread itself when you insert the core (it doesn't always do this too well so I tap them out first); or real microminiature ones.

Fig. 13 shows the second stage which worked just as well and also showed no need for neutralizing. I'm beginning to get just a little suspicious of this! Too much of a good

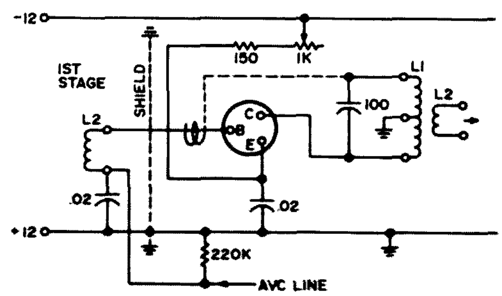

Fig. 13. Second *if* stage.

thing. The base input circuit is from L2 instead of through a capacitor. Same collector coil and circuit as the first stage.

For the third stage and diode see **Fig. 14.** Everything still going fine, with the collector coil having a larger secondary winding to the diode with ten turns instead of only three for a base input. The number of turns on this winding which feeds the diode detector and avc even though not critical, should be adjusted for best avc action and audio output. As mentioned before, you can play around with all kinds of separate avc diodes, avc amplifiers, S meter stages, etc., but let's try and keep this rig as straightforward as possible. With a two pi winding, tuned with a 6/32 threaded iron core and about 100 pf capacitor, as shown in **Fig. 14,** it works fine.

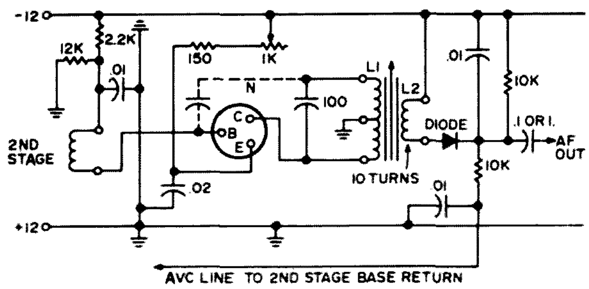

Fig. 14. Third stage, *if*, 6 m.c.

AVC

Pay attention to this item. Several little rules to watch. Do not put avc on the last *if* stage. Let it run full gain into the diode to give plenty of avc voltage. Choose a proper balance between the diode resistor R6, the avc line series resistor R6, and the bias voltage resistor R7. If you put too much dc voltage on the diode through the avc line the *af* will be distorted on low signals. If you put too much R (R6) in series with the avc line you won't get enough avc action. You could put a lot more avc action into the circuit like they do in car radios, with avc on the *rf*, the mixer, and almost everywhere, in order to help matters when you drive past those crowds of AM towers on the New Jersey flats, but you don't need that here.

With all the above details you should have a good *if* strip by now.

AF

This will be real short. Lafayette has a selection of transistor *af* amplifiers which work fine. You can get up to three watts, which is better for mobile work if you have that in mind. Get several because you'll need another one for the modulator, unless you

want to do a lot of switching between microphone and speaker, etc. You can even get three, one for the modulation checker when tuning up the transmitter. Once you use this trick, with a diode and padded earphones, plenty of *af* gain to keep your voice from getting to your ears through the air you'll never be without it. You can hear every bit of hum, distortion, etc. that can creep in, and, if everything is correct, your own voice coming to you through the mic, transmitter, and antenna just as it sounds to the lad on the other end of the QSO. With the exception of unwanted FM, if any. That is another story.

Assembly

When you finish these receiver units you will have the receiver half of a nice portable rig. I have found a simple carrying rack of plywood, with as many shelves as you need, and a dowel handle on top, sprayed with aluminum paint, to be very useful. The receiver is really very simple, just a standard superhet. It helps though to know you can plug in a crystal controlled oscillator chain and narrow band *if,* check the mixer without the *rf* stage, build more *rf* stages and add or substitute them as desired.

Leave shelf room for a modulator, transmitter, and possibly "high power" addition. Two watts? Five watts? Who knows what the future, along with a little more hard work (and $) on your part, will bring you? Mount the speaker in a little box, removable, so you can place it off the rack. Audio feedback gets to the tuner through the rack itself. Or you could use foam rubber mounting to handle that matter.

Final tune up

This can be troublesome. It was here. Quite a few cables to make up, but worth it in flexibility. 1) Antenna to *rf.* 2) *rf* to mixer. 3) Oscillator to mixer. 4) Mixer to *if.* 5) Mixer to *af.* I put two lantern batteries on the bottom shelf for a total of twelve volts, with the *af* amplifier in front; the *if* on the next shelf, and the *rf* head on the top shelf. A new and taller rack will be made up for the transmitter units later.

Checking back through the circuits you will notice cable matching input capacitors going to almost every base. Some judicious testing of cable lengths can help, because, unless you have a slotted line and do a real professional job on the SWR like when *someone else* is paying you for those extra days, be happy with a few standing waves.

A simple test signal unit with two tripler stages from a 48 mhz crystal, to 144 and then to 432, was used as a test oscillator with a nine volt transistor battery, a dipole, and a modulator, and placed about 100 feet away. Works fine but sure swamps the S meter. Then came a little glop of trouble. After all my warnings about frequency checking on multiplier frequencies, it happened to me right on my own bench. I tuned up the complete receiver, found the test signal generator on the dial, and proceeded to test the *rf,* mixer, and oscillator stages, using the full gain of the *if.* Nothing worked right, and no wonder, I had inadvertently tuned in one of the higher harmonics of the test oscillator over 500 mhz, right alongside of one of the Massachusetts UHF TV stations, and then, to make matters really sticky I had, also by mistake, peaked up the test oscillator near 525 mhz too!

On checking with an old but calibrated coax mixer, everything seemed to be over 500 megs. Which it was! Just part of the game of course, so, as I keep saying, check that frequency.

As soon as everything was put back near 432 the new job showed up as having real pulling in power. The *rf* and mixer peak up nicely, and the oscillator is quite stable.

With the front end as described in the text and figures, it is quite easy to get too much oscillator voltage into the mixer. Oscillator harmonics will then show up as CW signals, but tuning much faster on the dial, because when you move a megacycle at 432 the harmonic may move two or three. Reducing coupling into the mixer by either the capacitor or the oscillator link, or both, cures this. You don't need that much signal for a local oscillator.

Listening in a little

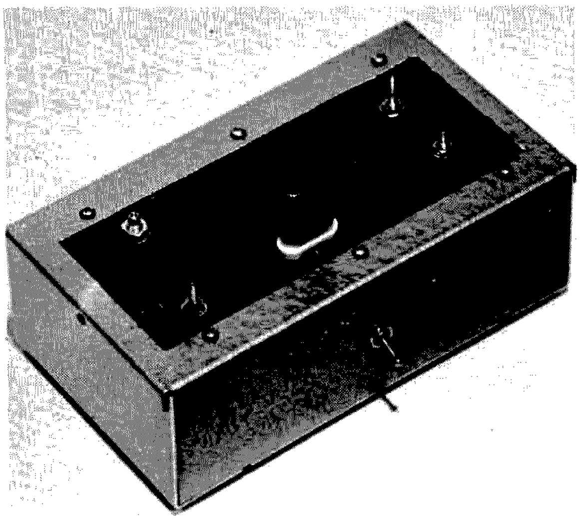
If you hear a strange humming noise, going up and down in volume, tuning very broadly, near 420, and again maybe near 500 mhz, shut off the rig, go outside the house, and listen for a big plane. It's one of those altimeters!

This was just an indoor antenna test before putting up the big beam outside. Also heard were the Mass. TV station on 425 mhz and a very loud pulse signal on about 430. It will be very interesting to see just how far two rigs like this will be able to maintain QSO's.

All I need now is that matching transmitter.

...K1CLL

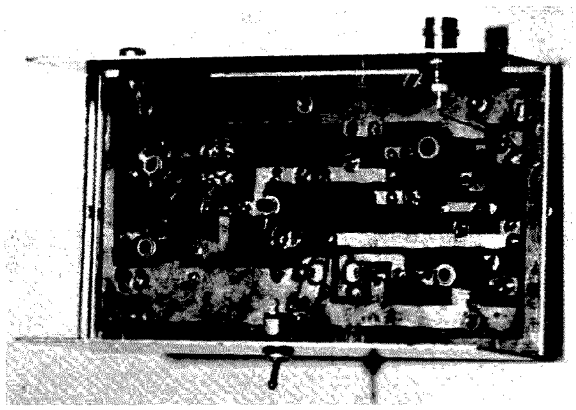
6-Meter FET Converter



William Deane, W6RET
8831 Sovereign Road
San Diego, California 92123

Recently there have been a number of interesting articles in the various amateur radio magazines describing the Field Effect Transistor (FET). The purpose of this article is to describe a simple and practical FET 6 meter converter. As you may know, the FET combines some of the best features of the vacuum tube and transistor and is rapidly being used in many new electronic circuits. FET's are divided into two main groups: the junction FET and the insulated gate FET. New terminology has been introduced to designate the FET terminal connections. They are the Source (cathode), Drain (plate) and the Gate (grid). The junction FET was selected for this converter to simplify the construction. This is possible as the Source and Drain are interchangeable in the JFET. The determination of which element is the Source or Drain depends upon the applied voltage.

The schematic of the converter is shown in **Fig. 1**. Three Texas Instrument TIS-34 FET transistors are used. These transistors are available for a $1.10. T1 is the *rf* amplifier, T2 is the mixer and T3 is the crystal oscillator. Note the similarity to a vacuum tube circuit with the Gate (grid) and Source (cathode) resistors and the Drain (plate) connected to the tuned circuit. No fancy biasing circuits are required. Although a standard transistor can be used in the oscillator circuit the simplicity of the FET oscillator is unique. The 50 MHz incoming signal is mixed with the 36 MHz signal from the crystal oscillator resulting in a 14 MHz output signal. In the crystal controlled type converter the receiver acts as a variable *if*. If used with the Collins "S" line, for example, you will be able to cover 50 to 50.4 MHz of the 6 meter band by tuning the receiver from 14 to 14.4 MHz. If you have a general coverage receiver you can tune the entire 6 meter band.



Bottom view of the converter shows the antenna coils L1 and L2 at the top of the photograph, with L3 in the center and L4 and L5 output coil at the bottom.

The photographs show the general layout and construction technique used. The converter is constructed on a 3 X 5¾ inch printed circuit board. If you have not had experience with printed circuit boards this will offer you an opportunity to try your hand. Small inexpensive kits for etching copper circuit boards are available at most radio stores and mail order electronic firms. The actual process is not too difficult for the average ham. **Fig. 2** is the layout of the board. Slight deviations or other arrange-

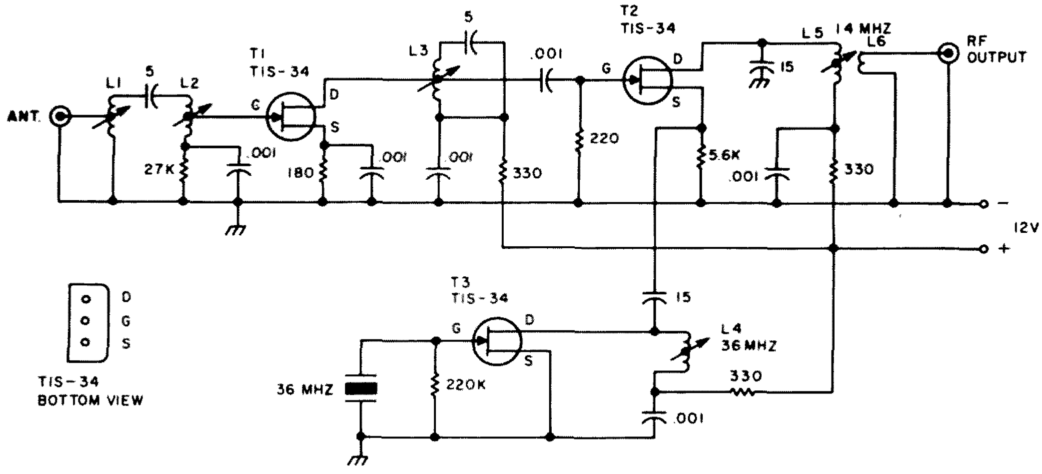


Fig. 1. Schematic of the 6 meter FET converter.

Coil Data

L1 - 10T #2BEC CW ¼" tuned form tap at 2T.
L2 - Same as L1 tap at 4T.
L3 - 8T #28 CW-tap at 4T ¼" form.
L4 - 16T #28 CW ¼" form.
L5 - 40T #28 CW 5/16" form.
L6 - 2T small hookup wire.

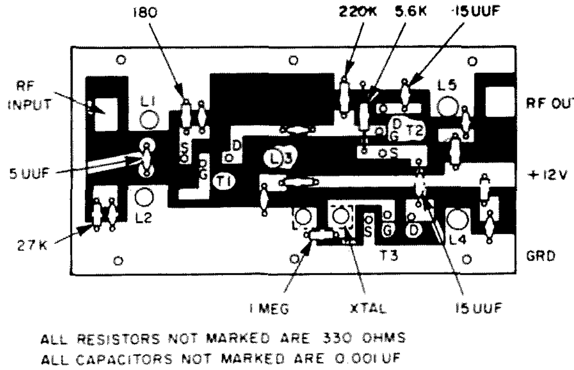

Fig. 2. Layout of PC Board.

ments can be made. I find it best to draw the layout on the copper side of the board in pencil and then fill in those portions of the circuit board to be retained with the resist paint supplied in the kit. Actually any type of model airplane paint works quite satisfactorily. The pc board is next placed in a small plastic or glass container and covered with the etching solution. (Not used in all kits.) The etching process takes 20 to 30 minutes, during which time the solution should be agitated by rocking the plastic container back and forth. When the etching process is completed the board is washed with water.

Following the etching process the resist paint may be removed with lacquer thinner or carefully scraped from the board. After the paint is removed, the board should be cleaned with steel wool or fine sandpaper. After the board is cleaned the resistors and condensers can be mounted as indicated in Fig. 2. The transistors, crystal socket and coils are then mounted. As mentioned previously, the Drain and Source are interchangeable so you don't have to worry how the transistors are installed as long as the Gate is connected to the proper terminal. The transistors require a supply of 12 volts dc. This can be obtained from a small battery pack or a standard 12 volt power supply. The unit requires 18 mA. If intermittent use is contemplated the battery pack will be satisfactory, but if you plan to have the unit on for long periods of time, a standard power supply is suggested. The unit is mounted in a small chassis box 6 1/4 x 3 1/2 x 2 1/8.

With the unit connected to the receiver, antenna and power supply, the coils can be adjusted for maximum noise in the receiver. This should allow the reception of signals and the coils can be peaked on the receiver "S" meter. In some areas channel 2 may cause some interference. If this is a problem in your area, a tuned circuit consisting of a 45pF trimmer and 5 turn coil ¼ inch in diameter can be installed between the rf input and the antenna jack to trap out the channel 2 signal. My thanks to Don Bidwell, for his photographs of the converter.

Compleat AVC

If it's worth and hour and a half of enjoyable labor and $5.00 worth of new parts to make a dramatic improvement in your receiver, heat up the soldering iron, pull off the cabinet and get to work!

One of my failings as a homebrewer is my tendency to modify and reuild my projects in occasionally successful efforts to improve their performance. The pursuit of excellence, and all that, you know. As a consequence, very few of my projects are ever totally completed. Take the avc circuit I described in conjunction with a product detector in a previous article. It was simple and worked beautifully . . . permitted overload only on the strongest local signals. But after a few weeks, I had to admit that the output of my 75A2 fluctuated just a little bit too much for really comfortable reception. The only answer was dc amplification of the avc voltage, a feature which was originally included in the receiver, but which I removed in developing the audio-derived

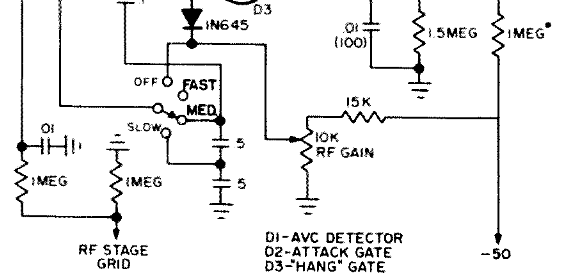

Fig. 1. Values shown in parentheses are to be used when deriving control voltage from the last *if* stage. *See text.

avc circuitry. I did not feel that the original circuit was very effective, or I'd never have removed it, so rather than replace it and try to improve it, I decided to start from scratch.

The result is the circuit shown in **Fig. 1**. It features dc amplification, voltage delay, fast attack and slow decay, and handles a wider dynamic range of signals than you'll find on the air. Detector overload is eliminated altogether. I have shown the whole avc system for a good reason: It is, in the strictest sense of the word, a *system*. Its performance and specifications depend on the proper relationships among all the components. If you build up the dc amplifier and try to stick it on your avc line, results may not be satisfactory. So if you're going to do it, go the route, or not at all.

I tried this circuit deriving control voltage from both audio and *if* signals with about equal success. Should you decide on the latter, it will be desirable to reduce the values of the input and filter capacitors as shown in **Fig. 1** for optimum performance. Also, it is more effective to take the signal from the primary of the last *if* transformer than from the secondary.

I chose a 6T8 for the convenience of having all the necessary elements in one package, thus eliminating several tie points and terminal strips. Depending on the physical set up of your receiver, you may wish to use a 6AV6 or 6AT6 with a silicon diode for the "hang" gate. Perhaps you can use half of a 12AX7 or other high-mu triode with germanium diodes for the avc detector and attack gate. Another important factor is the availability of proper B+ and negative bias voltages. The value of the cathode load resistor can be changed to accomodate different voltages, but B+ should not be less than 180 volts, and the bias should be -50 volts or better if you want to take full

advantage of this system's capabilities. If your voltages are radically different, the value of the cathode resistor should be varied to achieve the best compromise between satisfactory voltage delay and effective avc action. The purpose of the voltage delay is, of course, to prevent avc action on weak signals, permitting maximum sensitivity until a certain signal level is reached.

The operation of the circuit is quite simple. On weak signals, the rectified signal voltage is not great enough to overcome the positive voltage in the grid circuit, so no avc voltage is developed. When the rectified signal voltage exceeds the positive voltage, the triode is biased in the direction of cut-off, the cathode goes negative in proportion to the signal strength, the attack gate is forward biased, and a proportional degree of the negative bias is applied to the avc line through the "hang" gate. Should the rectified signal voltage be great enough (as when operating full break-in), the triode will cut off, and full bias voltage will be applied to the avc line, muting the receiver.

An additional form of delay is introduced by the voltage divider through which the avc voltage is applied to the *rf* stage. This keeps the sensitivity of the *rf* stage high enough to preserve a satisfactory signal-to-noise ratio on moderately weak signals which activate the avc but need some "help". This is not a technique to correct a design flaw, but rather allows the avc to act early enough to maintain satisfactory control over the output level without masking the signals in noise. Of course, as has been pointed out, on weak signals, no avc voltage is applied at all.

The divider sets the decay time constants of the system. As it is shown in Fig. 1, decay times of 140 milliseconds, 500 milliseconds, and 1 second are provided in the Fast, Medium and Slow positions respectively. Attack time is less than 75 milliseconds in any position.

RF gain control is achieved by biasing the avc line through a silicon diode, which prevents further loading of the line. The diode is reverse biased until the negative voltage applied through the *rf* gain control exceeds the avc voltage, so the control has no effect until that point. Beyond that point, the avc is inoperative unless an extremely strong signal would cause the avc voltage to exceed the *rf* gain bias. This would, or course, reverse bias the diode again, permitting the avc to take control. This method of control offers some interesting possibilities. Turning the avc switch to the off position bypasses the diode, loading the avc line heavily enough that the avc voltage is "killed". After you've used this system for a while, you'll probably find that you never have occasion to use the *rf* gain control at all. I guarantee, this is one avc that will be left on.

The superiority of this system is evident. As installed in my 75A2, it holds the output within 6 db on *all* signals, and I have yet to encounter any signal strong enough to overload either the AM detector or the product detector. Because of the delay, weak signal work on 6 meters is greatly facilitated. Signal levels which previously would not yield copy now give Q-5 copy, in many cases.

One final word . . . a high noise level can render the delay function of the system completely ineffective. However, the great benefits of amplified avc action are no disturbed. A good *if* noise blanker will make it possible to derive the full benefit of this avc system, and you should definitely consider adding this feature to your receiver. I'm presently developing a simple blanker, and when it's finished, *73* will be the first to know.

Leaky Lines

There's been a great deal of favorable comment about a newly formed net on 7255, called ECARS (East Coast Amateur Radio Service.) Evidently patterned after MWARS and WCARS, its prime purpose is to assist mobiles with traffic and weather information, run phone patches and so forth. I've sat in about a dozen times, and can report that for a new net it's doing a first class job. Membership is being formed up, with current rolls up to about 350 members, and they print a monitor which will be sent to all members. For information about joining, I suggest you listen, or better still, check in. This net looks like a winner, and I believe it will be around a long time. It starts around 6:30 A.M., EST, daily and goes till unconscious, as the saying goes. How about joining in on the action?

*

They had a really great turnout at the Harrison Sideband shindig, at the Statler-Hilton in New York. I saw lots of old buddies, and had a swell time, just roaming around. I gave them a start; they didn't expect me to walk in with a growth of chin whiskers. I sure got the horse laugh from a few of them, but that's okay. My beautiful Penny said she likes it, and that's good enough for me.

*

I missed the North Jersey DX Association's annual round-up. I had a prior engagement, unfortunately. I was sorry to miss it, as it's always a ball being there. Next year I'll make sure to keep the date clear.

*

No doubt, by this time, you are all aware that our peerless and redoubtable editor, Kayla, W2EMV, is getting hitched to Doc Hale, K4MWS, and is leaving the magazine for a life of connubial bliss down in sunny Florida, the Land of the Laughing Dollar. After 22 months of Dublin, New Hampshire's ubiquitous snowstorms, she is indubitably looking forward to the warmth of the tropics, and a life of soft ease, under the palm trees. I predict, however, that she won't forsake her Smith-Corona for long, and will be re-appearing in print from time to time. Congratulations, Doc, and much joy and happiness to you both, Kayla.

*

I'm soon going to be trying to work the repeaters on 2 meters, with a little NBFM rig, through the kindness of Chuck Bell, K3HHP. I don't know how much of this activity goes on up this way, but in some areas they're having a whale of a time with it. I should think that our hf bands will profit greatly with the burgeoning opportunities afforded by these vhf repeaters. A lot of qrm will disappear, and that's all to the good. I think that somebody with experience in the repeater field should write a piece about it. What say, somebody?

*

I've been carrying on a campaign, with the tacit approval and blessings of many others, to stop the idiotic use of meaningless drivel on the air.

When someone asks for my handle, I usually answer, "The handle is broken off; my name is Dave." I never, but never, say qth, Queen Roger Nancy, H..I... or even 73. Why use all this CW parlance when we have a perfectly usable language with which to express ourselves? Boring and trite at best, it gets to be moronic when poor band conditions do not necessitate its use.

By far, though, my pet peeve is the nauseating use of the royal or editorial first person plural. When a guy says, "we" or "us" in place of "I" or "me," I always ask him if he is a Siamese Twin, or if he has two heads. This practice sickens me. By the way, we all know what a linear amplifier is, but would someone please tell me: what's a linear?

Here's a commonly heard stupidity. A net is in session, passing traffic. Or perhaps it's a round table, just chewing the rag. All of a sudden, out of the clear blue sky, without so much as a "By your leave," someone interrupts the proceedings with an urgent sounding, "Break, break, break, break." At this point, of course, realizing that something imperative in the voice of the breaker commands immediate recognition; perhaps a catastrophe of unthinkable proportions has occurred, the NCS, or one of the rag chewers calls in the station.

I must add an editorial aside at this point. Fellows who wouldn't dream of sitting down at your table in a restaurant, or getting into your automobile uninvited, have no hesitancy about rudely interposing their unwelcome presence into a private conversation on the air. Just plain rude, that's all.

Well, anyway, the station is called in, since the occupants of the frequency are eager to render assistance to the emergency breaker. The following transmission, incredible though it may be, is what they hear.

"Fine business, Old Man. The handle here is Ignatz....Ignatz....Idiot, garbage, nosebleed, alimony, termite, zilch....Ignatz. Our qth here is Split Lip, Calichussetts. We just put a doo-hickey on our frammis here, by golly, and we wonder if you could give us a signal and audio report. By the way, Old Man, by golly, the rig here is a Duck, and the old hearing aid is a Goose. The sky wire is a double-whammy super Mark seven quadrical cube pointing in your general direction, Northeast by Southwest. Our linear is a Swinette, in grounded grid, with a dixie-cup readout. It's been doing a fine-business job for us, by golly. So whatsay, Old Man, how copy, H...I...break, break. Ooooooohhhhhh-ver!"

Well, what are you going to say to a jerk like that? I mean to guys like those? I mean...oh, the hell with it. He had more we's than a men's room. All that was missing was, "That's a big ten-four!"

Wait till I get to the guys who give you this: "See ya down the old electric light bill." And the big mouths who say, "From the beautiful snow-capped, sun drenched hills overlooking the peaceful valley of the Fugahwi Mountains, this is the voice of Penwiper, Pennsyltucky, saying, the very best of seventy-threes, seventy-sixes and eighty-eights, Old Man. May the bluebird of happiness light on your windowsill every morning, and may the old master brass pounder in the sky take a liking to you; and till we meet again, aloha, au revoir, auf wiedersehen, hasta la vista, and a rividerci, Old Man. Dit...Dit..." Oh, brother!

I wish that stations would refrain from calling DX stations on their own transmitting frequency. Lately, despite repeated entreaties to listen five or ten up, some guys insist on clobbering the DX in this fashion. It makes things rough for everybody, and certainly doesn't do the offender any good either. The best procedure is to listen to the DX operator, and follow his instructions, whatever they may be.

By the way, it is not legal to go down into the foreign portion to explain to another foreign ham that he is interfering and should change frequency, for when we do this, we are merely compounding the problem by adding to the interference. Plus

that. it's an open invitation to the FCC for a nice little pink slip.

There's been some discussion of late about broadbanding 75/80 meter dipoles. Quite a few lads and lasses like to work both the phone and CW segments, but have neither the space nor the inclination to put up two wires, nor do they desire the addition of a matchbox or L network, or other type impedance-adjusting device.

The Collins people once had an interesting configuration in one of their manuals. I believe it has been called a fan dipole. An extra length of conductor is soldered in at each side right at the feed points, then fanned out in a horizontal plane. The spacing at the ends is anywhere between five and twelve feet, depending upon available space. The resonant point is somewhat lower, so that the entire antenna must be shortened for a given frequency. This is, for all practical purposes, a section of a discone. I'm told that it effectively broadbands the dipole so that the entire 500 khz of the band may used, with pretty flat vwsr. Worth a try? I think so too.

I can't recall anything which has given me greater pleasure than the letters in April's QST, in response to the February editorial. For a long time it has been evident that hams are a heckuva lot smarter than some folks think. They are very much more aware of things than they are credited for, and their knowledge is not restricted to radio and electronics. They resent, rightfully, any efforts to limit their freedoms, just as any other citizen would. Especially resented is any idea that somebody else, because he holds some title or office, is fitted to decide such limits. Americans, by tradition, have respect for high office, but this does not mean that they automatically respect men who hold such office. They do not regard officials with any particular reverence. This very Republic was founded in the crucible of irreverence for autocratic authoritarianism, as exemplified by the British Crown, and it goes against our grain to accept with bland docility any type of dictatorial censorship against the free expression of opinion. In fact, in America, one of our most important traditions is the right to express unpopular opinions. And the degree of freedom which we enjoy, unique in all the world, is gauged precisely by the right of the individual to stand alone in an unpopular opinion, though he were opposed by all the rest of us. We regard that right as something sacred.

The letters which were printed, (and I can only gather by the huge proportion against the editorial, that there were very few letters for it,) clearly showed a high degree of understanding, were articulate and to the point. There is no question that hams are well-informed, involved persons, determined to safeguard their rights and Constitutional privileges against any incursion, whether from outside or within our own group. They understand the bankruptcy of the vigilantism proposed by the editorial. They recognize the folly of committing suicide to keep from being killed.

It is very clear that very few hams are about to accept a "Big Brother" with a proposal for self-appointed thought police, no matter how sacrosanct his position or office. Those letters in QST express more honest-to-goodness Americanism than a dozen civics text books. Makes me feel proud, when I realize the intellectual capacity of my colleagues in Amateur Radio.

Dave Mann, K2AGZ

Field Day Fever

Alan Shawsmith, VK4SS
35 Whynot Street
West End, Brisbane
Queens, Australia

Man, was I in double trouble. It was a long week-end. The kids were away with their grandparents at the beach. In an early morning, clear and mild, the YF and I were at breakfast on the sun porch. All should have been serene and happy. But, not so.

I had disgraced myself the night before, but that was not the end of it. I had made away from home plans without telling my OG. We all know what that means, particularly as she was planning a party and had been slaving these past two days to bring the house to its best.

Jadedly, I knocked the top off a boiled egg. My spirit seemed about the same as its contents; weak and soft.

I gazed across the table at the Nephritete-like head of my beloved and wondered at my devotion all these years. The shiny black hair tumbled as she bent over the morning paper, reading me the headlines.

"Drug running now big business off the East Australian coast. Racketeers continue to elude patrols."

"Do you think they use radio?" she asked.

"Who?"

"The dope smugglers."

"Yes, almost surely."

But my mind was on the week-end plans. How could I manage to tell her, especially after last night? I finished the egg, toast and coffee and felt a little more virile.

Every married male might be the man around the house, but the *subtle* master is the mistress of it. In my case, should I threaten to step out of line, I was given the "ego boosting" treatment. A sort of confidence trick it is really. With a meaningful look from the XYL's gypsy-like eyes, I am reminded every so often that I am a gentleman. How could I ever be unethical. Thus my will is imprisoned and conduct assured.

But this morning the male was about to roar. I *was* going away for the week-end, because arrangements had been made, even if they were concluded through a slightly inebriated haze, the night before.

"Honey," I said in a voice that was meant to be quietly final, but in effect came out weak and pathetic.

"Forget about the party tonight. I want to take you away for the next few days."

There was no immediate reply. Then she raised her head and looked past me into the kitchen.

"What are you going to do about *those*?"

"Ah yes, *those*." Oh my shame, I must explain.

Last night, leaving the pub after my quota of a quick two, I ran into Harry Watermaine. Field Day fever possessed him. (Actually I had forgotten about the event.)

"Say," he enthused. "I know of a DX Utopia. The perfect QTH. Optimum angle of radiation and everything is S9 plus. I'm taking the car and caravan. You must come."

Each succeeding beer made the idea seem rosier. It was late at night before the final details were settled and I could hardly wait.

Unsteadily creeping up the front porch steps, I knocked over a milk bottle. End over end, it went shattering the quiet.

"Shh, shh," I hissed, "You'll wake the YF."

"Where the heck is the door key." Why does a man need so many pockets. Top and bottom, back and front, inside and out. Eventually, it was located but a lot of 10 and 20 cent pieces were spilled in the fumbling process. "Never mind, I'll retrieve all in the morning."

I awoke with the expected. Headache and heartburn and my excesses demanded I rise immediately. Foggily the loose change on the porch came to mind. Unsteadily I opened the door and stepped back in amazement. The silver money was gone but in lieu, stacked phlanx-like, were 27 bottles of milk. Surprise quickly gave way to irritable temper. "A smart-alec milkman," I mused. What a cheap piece of petty capitalistic exploitation. Then through my misty hangover the ridicu-

lous began to dawn. Tottering back to bed I burst into a loud guffaw of laughter.

Sleepily, the YF opened her eyes and regarded my mirth suspiciously.

"Sweetheart, is there any rum in the fridge?"

"No. Why, haven't you finished yet?"

"Ha, ha, ha. Where's the cat?" This brought her bolt upright.

"How should I know. Are you all right? What's so funny?"

"Like a bath in cow's juice?"

Disbelief crowded into the half-awake face.

"You're nuts—or in the DT's," she said.

"Aw, fair go kid. I'm okay. That smart Charley of a milkman just sold me 27 bottles of milk."

This was too much for my Helen. She fell back and pulled the bedclothes up over her ears.

"Go and have a cold shower—and shut up," came the muffled voice.

*****

So, now I suggested we put all those bottles in the freezer until our return. "From where—and with whom?" The YF challenged coldly.

Remembering her planned party, I prepared myself for the ego build-up bit. "Up to the Lost World country. It's AR Field Day tomorrow. Monty Watermaine is taking his gear—and us."

"NO."

"Aw gee, Honey," I pleaded. "Field Day only comes once a year. We can hold a barbecue anytime."

"The party's off. When you didn't come home last night, I rang no one. A trip to the mountains is okay—but not with 'Gusher'." (This is Monty's nickname. Aptly tagged because his effacious manner irrates most of his friends.)

"No," she insisted. "Not with that arty eccentric. Besides you only want me along as a char. While you two drool over the rig, I'm the one to attend your creature comforts—or act as a rigger on the sky hook."

She banged the newspaper on the table in one of those small transitory piques, I had come to know so well.

"Look my Sweet," I implored again. "This is a chance too good to miss. Monty has found a DX Eldorado. You know, a place where reception is super dooper. All sigs S9 plus."

"Why Gush—and how did he locate it?"

"Oh well, he paints you know and seeks out virgin country for his landscapes. Sometimes he takes a radio along."

"Rings phoney."

At that moment, there was a mounting roar from outside.

"Oh that'll be the pantechnicon for the Hunter's. They're moving you know. One more TV griper off your back, eh? I must wish them good-bye."

I let the barb pass and stared miserably at the vibrating dishes. The milk bottles tinkled in sympathy. My heart rose in my throat and what courage I have trickled into my slippers.

She was back in a second; wide-eyed.

"Hey, it's Gusher and he's towing a railway carriage."

"It's his caravan," I said feebly.

"Where did he buy it—from a circus or the Government?"

"No, it's homebrew."

"It's like a tired daschund. Sags in the middle. Who painted it?"

"He did."

"Why so monstrous?"

"He uses it for his art besides AR. Has a piano in it too. He plays you know."

"A black square Buick and a tangerine and mauve caravan. Ye Gods."

"...and the interior is psychedellic," I snapped irritably.

"How could I drive away from here in that?"

"Shame. Where's your integrity?" It was my turn now.

"Monty," I called from the door, "won't be long."

In the bedroom the YF was camouflaging herself behind dark sunglasses and a large bandana.

"I can see," she said, "that if I care for your safety, I have no choice other than to come along and protect a couple of fools from themselves."

I sighed deeply.

*****

It is best to draw a veil over the trip to the mountains. We eventually made it, but the fates must have been in a benevolent mood. Enroute, a service station pad was cleared to allow us to draw in and fill up. The proprietor was paid for his pains by Monty driving off with most of the stations advertising bunting. Off the main road the Buick's brakes weren't up to a sudden stop and we nearly removed a farmer's cattle gate by flattening it; and a mile further on, the caravan's radio aerial sliced off someone's telephone wires. After several stops to allow the old bomb's

gasping, wheezing motor to cool down and recover its strength, we suddenly emerged from a tropical rain forest, out on to an elevated plateau. A magnificent panorama surrounded us. Behind were the towering mountain peaks, and away below, now hazy in the fading light ran the ribbon of coastline. A white string between purple Pacific ocean and lush green vegetation. But even up here human habitation was apparent. Well-tended banana plantations nestled against the slopes.

"Monty," I said softly. "This splendor humbles me."

But Gusher was impatient to test his theory and in no mood for philosophy. Besides, he'd been here before.

"See that Flying Fox just there. It's about half a mile long. What a great long wire antenna, if I swing a bare wire over it for a lead in. No one will be using it over this week-end." (A Flying Fox in this part of the world* is a long cable or wire, strung from one elevation to a lower one, down which bananas and crates, etc., are slung to a central point. A great manpower saver.)

"Okay," I said, "it's your gear—go ahead."

Monty deftly weighted his lead-in with a stone and skillfully threw it so that it wound around the Flying Fox.

"Boy Scout days," he smiled at my admiration. "Let's have a listen first up and see—Wow."

He threw the wire from his hand. "That's HOT—it burnt me."

He sniffed a forefinger. "Yep, that wire's got *rf* on it."

"Impossible," I said, gingerly testing it. "See—nothing. The altitude's got you," I ribbed.

"Well, let's go in and tie it to the receiver."

The set was barely warming up, when a harsh, distorted voice crackled through the speaker.

"—use alternative rendezvous at 03. Two drops."

The S meter was slammed hard against the pin. Monty frantically wound back the controls.

"What was that? What frequency?" I asked surprised.

"Well the receiver was on 28 mcs but it was all over the dial. It could only be a local sig. Probably outside the ham band because the image rejection in this ole set is crook at 30 mcs."

Suddenly it came again. This time the full text.

**Queensland, Australia*

"Z1, Z1. Traps trolling the reef. Use alternative rendezvous. 03. Two drops. Use caution. Confirm."

Monty reached over and touched the aerial.

"Yep, that Fox is being used as an *rf* line, for sure."

We left the receiver running and sat in hopeful silence for something further, but nothing eventuated. We began to speculate on it's significance.

"The Fox disappears into those trees down there," I observed.

Helen, my YF, said, "If I know my geography, the only reef east of here is Shark Reef, and the newspapers have been saying it is a likely spot for dropping contraband."

"Let's examine the message some more," I said. "Traps in criminal vernacular means the police or the law. 'Trolling' is patroling. '03' is most likely 3 a.m. East Australian Time, and 'two drops,' two packages or containers."

"Put like that, it sounds ominous, but couldn't there be quite a simple explanation. Maybe it's just a message for fishermen somewhere?"

"What, so far from the coast and not showing a proper aerial?"

"Who'd look for a drug gang up here," Helen said.

"Aw heck, let's ignore it. We came up here to test this QTH and work DX, so why worry about it. I can sling up a Ground Plane in ten minutes. I've got a tri-bander pre-cut stowed here in the caravan." Field Day fever still gripped Monty and he was itching to get into the thick of things.

"There's a law that says every citizen is duty-bound to report any criminal act or what appears to be an irregularity," Helen said.

My YF was at it again, setting me up. Her eyes were directly on me and the meaning clear.

"If we report this and it turns out to be authentic, we'll look like a trio of nosy irresponsibles with red faces," I cautioned.

All sat silent, ruminating. Finally, I said, "If anything is to be done, it must be now as 03 EAST is only hours away. Will that ex-disposals TX work Monty—and on the small ships base frequency?"

"I'll try it and see."

The set-up in the caravan was a wonder to behold. Being unmarried, Monty could afford to indulge himself. His gear was a mixture of new and old. The TX in mention had general coverage.

"We'll load it into the short vertical on the caravan roof," explained Gusher.

"Honey," I beckoned, passing her a pencil. "I'm going to try and contact a base station north of here. I want you to take down the text of what passes both ways–for the record."

In response to my first call, back came the reply. "You're loud and clear. Have you a message?"

The text of what we had picked was passed and the request was made, that if the message lacked authenticity, please pass to the proper authorities. After identification, we signed off–quickly.

"Probably think we're the phoney's," Monty voiced the guilt within us all. "We've just operated outside the limits of our license."

"Yes, but with good intentions."

"–which may be hard to prove. What if the sender of that message picked up our transmission?"

The YF interposed. "He's either laughing his head off at a couple of silly hams–or if we've hit the jackpot, slipping a slug or two into his shoulder gun and coming to find us."

"Please, Helen," I demurred, "don't be so sinister. You make it sound like a TV movie."

A sort of frustrated, embarrassed silence descended upon us as if *we* were the wrongdoers. We had done ourselves as far as Field Day activity was concerned. All that was left was to pack up Arab-style and fade into the night.

Defeated, I went to the caravan door and looked down into the night to where the Flying Fox disappeared into a clump of trees. It all seemed so unlikely that I began to feel we were the victims of altitude hallucinations. But worst of all, I had spoiled Monty's week-end. So, with the question of the site as a DX Utopia still unresolved, we set the old Buick moving at it's lowest possible revs and crept off the plateau on top of the Lost World and began our descent into the mists and vapors of the heavily scented rain forests. Unbridled imagination is truly a bolting horse. On every bend I expected to see a road block and a couple of characters standing in our path. The sight of the highway back to town brought a big sigh of relief.

Back home, the noise of our tired arrival probably woke the neighbors but even the YF was too travel-weary to worry.

"Stay and have a kip," I invited Monty. "You look dead beat Om."

"Me too," yawned Helen.

*****

The sound of the piano being played brought me out from the last layers of sleep.

Must be Gusher keeping his hand in. Whew, it was hot. Must be late in the day.

The OW breezed into the room. Refreshed, prim and pert. I could see immediately by her eyes that something was up.

"Log," she accused. "We tried to tell you the news earlier, but stirring a dugong from its sleep is impossible. So we just let you be."

"Wa-ssat? Er–thanks. Oh, what news?"

"Gusher, will we tell him or leave it to the reporters?"

"–reporters?" I was now on my feet. She pushed me down again.

"We scored a bullseye. They've picked up some of the smuggling gang and expect to arrest others. The newspapers want to interview you and Monty."

The weight of sleepiness vanished. "What? Great, great! When are they coming?"

"You'd better get dressed because we're having a party tonight. May as well cap our little achievement with a little get together. Monty's staying to play piano."

"That message?" I said curiously. "It was rather vague. Fair dinkum did–?"

"Yep, caught 'em red-handed, and it seems like the credit's yours and Monty's. Appears the drug runners were able to obtain prior info on the patrol's movements but we settled that."

Life suddenly seemed warm and rich, like a perfect spring day–or nearly so. There was still the matter of the bottles of milk.

*****

The time was 3:30 a.m., and the last guest had bid his farewell. What a wonderful evening! Monty's skillful fingers had charmed away the irritation his mannerisms had caused the YF. We had enjoyed the wit and humor of friends, my beloved's wonderful cuisine, and the radio news flash of our little drama up on the Lost World.

Helen appeared with the last edition paper in hand and bounding with impish mischief. Opening the fridge she peeked in at the milk bottles–all 27 of them, then came close and slipped her arms around my neck.

"Darling," she said, "there are times when you are magnificent–LOOK."

She waved the paper under my nose. It's headlines read: *"Milk Strike. No Deliveries for 4 or 5 Days."*

She chuckled, I laughed. We both laughed and laughed.

A Field Day to Remember

Fascinating, frustrating, or fun, Field Days are good tests of amateurs' engineering and operating ability. Although I had helped with two Field Days, I had done little operating because the other operators were 40-wpm men with contest experience. My contributions had been to design the antennas and to "supervise". This spring two 15-year-old Novices, Dave, WN8WMV, and Ron, WN8WMR, decided that we ought to have a Field Day. The new rules looked interesting, but there seemed to be too little time. Lack of success in building transistor transmitters had discouraged me, and I was very busy. However, Ron and Dave were persistent in their "encouragement", and I said we would have a Field Day, if we could get ready in time. My "Field Day receiver", built in 1966 as part of a "mental conversion" from tube to transistor thinking was designed for operation on 80 and 40 meters. It works well, is stable, and selective. We were determined to have battery operation for that 1.5 battery multiplier. We also wanted to have a ten-watt CW transmitter so that our power multiplier would be four. At this point, a "little bit of luck" intervened. I was given a 6-volt vibrapack that would put out 300 volts dc.

Flash! Idea! A tube transmitter! Perhaps one or two Command transmitters converted to 6-volt tubes might work. More luck! George, K8APT, donated a car transmitter from which two coils and a variable condenser had been removed. (The transmitter had a 5763 crystal oscillator and a 2E26 amplifier in a circuit taken from the 1959 ARRL Handbook.) The variable condenser was replaced, and two slug tuned coils were wound that could be tuned to resonance in both the 80 and 40-meter bands. The heaters were re-wired for six volts, and we had a transmitter. Would the vibrapack run it? Yes! Could the power be held down to ten watts? Yes! The vibrapack had a switch to change its output voltage. How about a vfo? A modified BC-457A Command transmitter with a 6J5 tube in place of the 1626 oscillator tube and with a shielded wire from the grid pin of one of the 1625 tube sockets to the car transmitter's crystal socket, provided a stable vfo. Break in? Yes! By mounting a VR-90 voltage regulator tube on the vibrapack to control the oscillator voltage, and by keying the whole transmitter in the B- lead, break-in was possible. The transmitter combination had a very good note and was remarkably free from chirps. The vfo and car transmitter were mounted on a board along with a telegraph key, a voltmeter, and a milliammeter so that the power input to the final could be calculated at all times.

With a receiver, a transmitter, and 6-volt storage batteries, all that was now needed were some operators, an antenna, a means of charging the batteries, permission to use River Rouge Park, a tent, and a few other items such as suitable lamps, tables, chairs, etc.

Ron had a tent, a lawnmower engine, and a 6-volt car generator. He worked long and

Ron and the battery chargers in front of the sound baffle.

hard to get the right combination of pulleys, belts, and generator field resistances so that my 6-volt telephone line batteries could be charged.

Field Days are always cooperative projects, and we needed more manpower. Arnold, WA8OVY, a technician, promised to help us "set up", and offered the use of his 12-volt trailer battery. To charge this battery, I purchased a 12-volt car generator for \$3.00 and mounted it on some boards with another lawnmower engine, some switches, and resistors.

In the search for manpower, I stopped at a house that had antennas and a car with an antenna. There I met Chuck, WA8WAH, and was glad that he was not a "CBer". I liked Chuck and invited him to join the group. Chuck offered to take his Heathkit HW-12A, 75-meter SSB transceiver out of his car for us to use on Field Day. (Being strictly a CW ham, I thought this might be good to make a few contacts when the CW operators got tired. Later, Field Day really educated me to the value of SSB!!!!) Thus, our working group consisted of Chuck, Arnold, David, Ron and me. I was the only one who previously had participated in a Field Day. Although we lacked experience, we had much enthusiasm.

Preparing for Field Day required much thought and work. We carefully studied the rules, and decided that such a small group should not attempt to have more than one transmitter on the air at any one time. By operating Class 1-A, only one transmitting antenna would be needed. We wanted to make each contact count as much as possible. By keeping the CW power 10 watts or less, each contact would count 18 points (independence of power mains 3, times battery power 1.5, times power multiplier 4). For the 75-meter SSB contacts, the power multiplier would be only 2 (50-200 watts), so each SSB contact would count only 6 points. According to the rules, we could get 200 points for using emergency power and 200 points for publicity. *The Detroit Suburban Newspapers* kindly published an article which told of our plans and explained the purpose of Field Day. The article also explained that *our group* would use equipment designed and constructed *especially for portable and emergency operation*, and would not merely run home-station equipment with a portable alternating current generator. Since we had no experienced contest operators, we felt that we would do well to get 100 CW contacts. We thought we could earn 2200 to 2500 points, (1800 for 100 CW contacts, plus 400 "bonus points") plus a few more points from SSB contacts. There was also a possibility of earning 200 more "bonus points" if we could get a message through to the Sections Communications Manager.

To get permission to use a high flat place in River Rouge Park, a letter was written to the Superintendent of the Department of Recreation, phone calls were made, and the park Supervisor was visited. The police were also notified in advance and given a copy of our letter from the Department of Recreation granting us permission to use the park.

Planning and construction work continued whenever time became available. Gooseneck lamps were fitted out with tail-light bulbs and battery clips. Pieces of pipe were collected to be driven into the ground to hold the guy wires. Spare tubes, spare spark plugs, an absorption type wavemeter, and other small items were collected. Lists of things to take were made.

The most important part of any radio sta-

Chuck, Arnold, and the batteries. Chuck's right hand is on the power supply of the HW-12 transceiver.

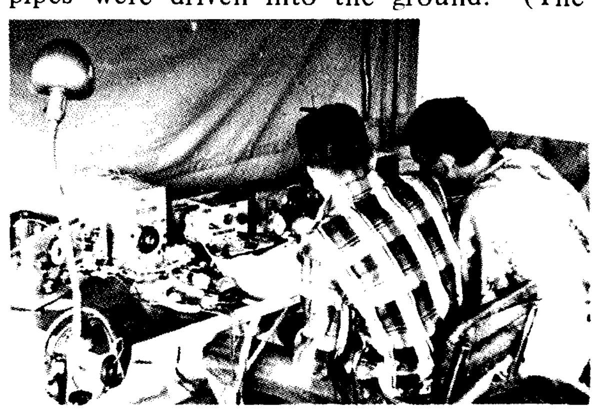
tion is its transmitting antenna. To be effective, a transmitting antenna must have three important characteristics: (1) resonance to the transmitter's frequency; (2) efficient transfer of the radiofrequency electricity from the transmitter to the antenna; and (3) height above ground. The Field Day antenna planned was an "olde tyme centre fed zepp". The two top sections were each to be 66 feet long connected to 64-foot-long open wire tuned feeders in the center of the 132-foot antenna (66 feet either side of the center where the feed line is connected). Thus, on both 40 and 80 meters the feeders could be voltage fed from a parallel tuned (center grounded) antenna tuner, link coupled to the final tank coil of the transmitter. Fifty feet of center height was provided by 2 by 4's, a 12-foot dowel, and fishpoles clamped together. The guy wires were fastened to the top of the 12-foot dowel. The ends of the antenna were about 25 to 30 feet up, one end in a tree, the other end held up by a 16-foot 2 by 4 to which was clamped a small sailboat mast. An open wire feed line was made of No. 14 enameled wire separated by 2½-inch wooden spacers that had been boiled in paraffin. The antenna wire was somewhat thin (No. 20 or so taken from an old loudspeaker field coil), and we twisted nylon string around the wire to support its weight and prevent the antenna from stretching. The antenna and feeders were rolled up on a detergent barrel and stored until Field Day. The four guy wires (broken electrically by "egg" type insulators) were coiled up and stored inside the barrel.

A week before Field Day, a practice session was held in my yard to try out the CW equipment and the six-volt lawnmower-driven generator. (The Heathkit HW-12A and twelve-volt generator lawnmower engine combination were not tried out until Field Day itself.) Ron had a 100-foot-long cable made up of three No. 8 wires which was used to take the dc charging current from the generators to the batteries. This 100-foot distance and a sound-absorbing baffle kept the lawnmower engine noise from being too loud.

During the "dry run", the home antenna was used, and several contacts were made before something "blew" during a QSO with VE3FPM. A .1 mfd 200 condenser in the vibrapack had shorted and was shorting out the telegraph key! The condenser was replaced with a .1 mfd 400-volt condenser, and there was no more trouble. This one correction made the practice session worthwhile. At the practice session a 64-foot piece of wire was cut for the receiving antenna, and a checklist of things to take was made. (In spite of the checklist, when Field Day came, the sledge hammer was left behind!)

There was also mental preparation for the Field Day. In 1966, I purchased a second-hand "bug" (semiautomatic telegraph key) and learned to use it to increase my sending speed. For three weeks before Field Day, I tried to get on the air often operating at as high a speed as possible. (I was probably up to 20 WPM by Field Day.) David, WN8WMV, took code practice every night from W1AW and got his code speed up to 15 WPM. He planned to help with the logging.

The big day came suddenly. In the morning, the equipment, lumber, food, tent, ladder, cot, chairs, table, batteries, antenna, wire, and generators were put near the garage driveway. At about 2:00 pm three loaded cars started for River Rouge Park. At the site, the cars were unloaded, and the long wait (15 minutes) until 1900 GMT began. At 1900 the antenna lumber was put in place, and with a good posthole digger we started digging the four-foot-deep hole into which the eight-foot-long double 2 by 4 center post was put. The long double two by fours were bolted to the bottom of the center post. The center of the antenna was fastened to the top of the fishpole section. The middle sections of the center support were clamped in place. The north end of the antenna was fastened to a rope in the tree. The south end of the antenna was fastened by a rope through the pulley in the top of the sailboat mast, and the antenna was walked up into place. Next, the four guy wire pipes were driven into the ground. (The



Chuck and Ron making contacts on 75 meter ssb. The equipment visible includes the CW station and the antenna tuner.

sledge hammer was badly missed!) The guy wires were fastened to the pipes, and the antenna was "rarin' to go". Next the tent floor was put down near the end of the feed line, so that the antenna feed line could be taken into the tent. As the tent was being put up, the folding picnic table was put up on the tent floor. The station equipment was set up on the table. The batteries were put outside the tent door. (To keep the acid of the batteries from injuring the tent.) The vibrapack was connected up, and we were on the air at 21:23 GMT, before the tent was completely assembled. Later, the generators were connected to the batteries through the 100-foot power cable. Seven 40-meter CW contacts were made before 2200 GMT. Field Day CQs were answered and, to our surprise and delight, most of the stations came back giving us good reports, 569, 579, 589, etc. The ten-watt transmitter with the big antenna was really putting out!

David's code was better than had been expected. His log keeping made it possible for me to concentrate on making contacts. David also made some contacts himself running crystal-controlled in the 40-meter Novice band.

At 2303, Dave and I were tired enough to let Chuck try his 75-meter SSB transceiver. The antenna tuner was connected to the output of the HW-12A, and the transmitter was carefully tuned up. At 2320, the first SSB contact was made, and in 16 minutes nine other contacts were made. What a terrific surprise to this "dyed in the wool" CW operator! Although Chuck had never been on a Field Day before, he operated as if he were an experienced Field Day operator. He instinctively had the knack of getting contacts quickly and with as few words as possible. Ron did the logging for Chuck. At one time, three contacts were made in less than two minutes. With 180 watts P.E.P., the HW-12A and the big antenna were putting out a loud signal. Some stations said the signal was the loudest on the band. (The 12 volt generator and lawnmower engine, that had not been previously tested together, worked beautifully.) SSB worked so well that we wished that we had a way of accurately measuring the input plate power of the final so that we could cut it down to 50 watts, so as to have a larger power multiplier. We think that nearly as many contacts could be obtained with a signal less strong. (We shall take care of this item next year!) The "few extra points" from SSB turned out to be many, many points, 1146 to be exact!

Dave and I stayed up all night working 80-meter CW. Early in the morning, we heard the Sections Communications Manager, W8FX. We were tired, but by "hook or crook", and with much repetition, we managed to get the 200-point message to him.

The rest of the day was spent either with 40-meter CW or 75-meter SSB. We operated until 2155 Sunday afternoon to try to get as many contacts as possible. In all, there were 109 CW contacts counting 18 points each, and 191 SSB contacts counting 6 points each.

(On September 10, 1968, we received a QSL card confirming a Field Day contact from W5US in Texas that would have given us another 18 points. The report said that our signals were 579.)

At the end of the Field Day period, we were sleepy, tired, but very happy. We were thinking about how to improve our score next year! However, even if we were to earn 10,000 points next year, we do not think it really could be a better Field Day than the one we had this year *as beginners*.

This was the Field Day that we shall never forget!

...W8BVU

Sunspots? *Who Needs 'Em for 6 Meter DX*

Morgan Monroe, K7ALE
224 Home Street
Moscow, Idaho 83843

Stop! Don't stow that six meter beam in the garage just because someone said the sunspot cycle is declining. The cycle is on the way down but that doesn't mean the end of vhf DX for those who know how.

Many six meter enthusiasts, particularly some who have discovered the pleasures of 50 mhz operation in the past five years, fear that 1968 marked the end of everything but local-area ragchews and net check-ins on ground plane antennas until the sunspots peak again a decade or more in the future. Not so.

Keep that six meter beam high. Peak up your 50 mhz gear. For many of you, the best is yet to come.

If the declining years of sunspot Cycle 20 (the next five or six) are remotely like the waning years of Cycle 19 in the period from late 1958 through 1963, 50 mhz DX possibilities should be plentiful for those prepared to exploit them with knowledge and operating skill. But, you'll need more than a corroded ground plane and poorly-aligned receiver to make the best of them.

Big power? No, that's neither necessary nor desirable.

Working six meter DX consistently is an amateur activity in which, literally, knowledge is power. Six or seven clean watts to a good antenna system does the job nicely. Twenty or 30 watts assure that you can work virtually anything in the world you can hear.

Successful six meter DX operators invest most of their effort and funds in efficient, directional antenna systems and sensitive, reliable receiving equipment. Above all, they learn everything possible about propagation effects that account for 50 mhz DX frequently missed by less informed operators. That's why knowledge *is* power on six. With an understanding of propagation effects, an efficient antenna, and good receiving equipment, you need very little transmitter power to rack up an impressive DX score—with or without sunspots.

Those who have studied the vhf segments of the amateur spectrum carefully in the revealing years since World War II, know that some of the higher frequencies offer excellent DX possibilities in periods when lower frequencies are deep in between-sunspot-peaks doldrums. This is particularly true of the six meter band, a true DX part of the spectrum for those who know how, why, when and where.

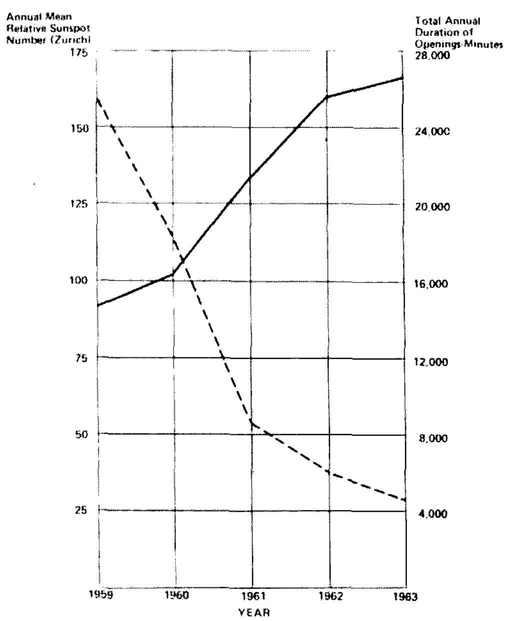


Fig. 1 - Relationship between annual duration of 50 mhz band openings, in minutes, and annual mean relative sunspot numbers as determined by the Swiss Federal Observatory at Zurich. Solid line indicates annual duration of openings (read on scale at right); dashed line indicates annual sunspot numbers (read on scale at left).

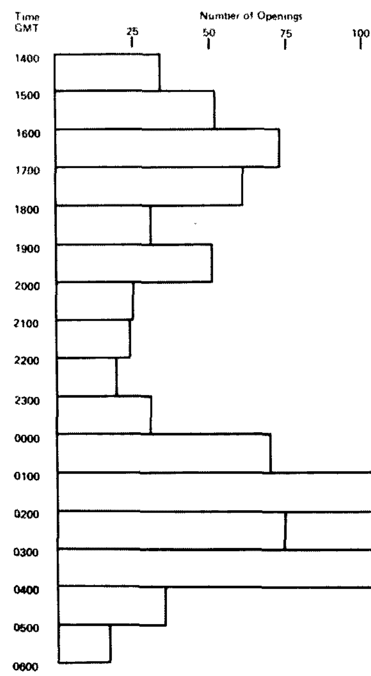

Fig. 2 - Beginning time, to nearest hour, of the 808 six meter openings recorded during the 1958-1964 investigation.

Older vhf operators perhaps recall the five-year investigation of 50 mhz propagation effects that my wife, K7ALF, and I conducted during the declining years of sunspot Cycle 19. That carefully-controlled study was initiated late in 1958, a full year after Cycle 19 had peaked and started down, and continued until January 1, 1964.

The most significant single finding of that 27,855 hour research effort demonstrated that sporadic-E propagation supported six meter DX opportunities *increased steadily as the sunspot cycle declined.* **(Figs. 1, 2; Tables A through H).**

Table A
COMPARATIVE SUMMARY
Six Meter DX
November 1, 1958–January 1, 1964

	1958 2 mos	1959 11 mos	1960 12 mos	1961 12 mos	1962 12 mos	1963 12 mos	Totals or avg.
Avg. mean sunspot number (Zurich)	184.8	159.0	112.3	53.9	37.5	27.9	—
No. monitored days	61	335	366	365	365	365	1,857
No. days band opened	45	99	126	101	113	109	593
No. band openings	70	121	169	140	152	156	808
Total mins. band open	6,197	14,797	16,326	21,316	25,594	26,494	110,694
No. states heard/worked	19	42	30	46	44	40	50
No. foreign prefixes heard/worked	18	11	15	7	10	6	40

Our investigation further showed that the six meter band opened between the Arizona study site (we have since moved to Idaho) and regions *outside* the continental United States in 62.3% of the 61 study months during the constantly declining years of Cycle 19.

But that's just part of the story. DX of one kind or another, foreign and domestic, was recorded in *91.8% of those 61 months,* **(Table D).**

If the waning years of Cycle 20—those from now until 1974 or 1975—are only two-thirds as productive, they will offer six meter DX in more than 60% of all the months during the next five or six years. That's a lot of DX, so keep those beams up and get ready. Sporadic-E (E_s) DX openings should begin mounting this summer.

Some of the things we discovered during the downfall of Cycle 19 can be helpful to you throughout the present sunspot decline. All pertinent data from our 1958-1964 records are contained in the charts and tables herein. This information can help you work more DX with less effort. And remember that at no time during the investigation did we feed more than 27 watts to the antenna. All DX recorded in the first five months of the study was worked with an output of only *seven* watts.

If you aren't familiar with our research, all of which was done on AM, you should know several things not indicated in the statistics. Some of our principal findings were

in sharp disagreement with widely-accepted theory. That is due, in part, to the fact that much of the DX heard and worked during a sunspot decline is via E_s propagation, a phenomenon about which little was known at that time. Even now, much remains to be learned; that's one of the fascinating things about working 50 mhz DX.

Sporadic-E propagation is the so-called "short skip" form resulting from unexplained, exceedingly high ionization densities occuring sporadically in the E layer of the ionosphere; hence, the term "sporadic-E." Such enhanced densities are capable of reflecting radio waves of much higher frequency than are reflected by the E layer under normal ionospheric conditions. They are therefore extremely helpful to six meter operators who know how to use them.

Unlike the F_2 form of propagation, which on six meters is associated only with high levels of sunspot activity, E_s propagation possibilities on six are in *inverse* ratio to sunspot numbers. As the numbers drop, E_s band openings increase and are of longer duration (Fig. 1). Our 1958-1964 research established this previously suspected, but unverified, phenomenon beyond doubt, at least so far as six meter operating conditions and Cycle 19 are concerned.

*Indicates prefix heard but not worked

Don't let that term "short skip" fool you. Six meter E_s openings normally permit working stations from a few hundred to 1,700 miles distant. But at times there is multiple reflection, termed "double hop," which makes many solid contacts possible well in excess of 3,000 miles. Our longest double-hop qso during the last sunspot decline was 3,300 miles. We did it in June 1963 when the mean monthly sunspot number was just 36.6, far below the Cycle 19 peak of late 1957.

E_s openings have two substantial advantages over F_2 openings on six. They are not frequency critical, which means you can work DX just as well at 50.5 or 50.8 mhz as near the bottom of the band where qrm is likely to be heavy, and they last longer; an aid in building up your DX score.

Another form of propagation which is wholly independent of the sunspot cycle is termed "tropospheric" because the phenomenon is associated with the earth's troposphere rather than the ionosphere. There is also much yet to be learned about this form.

As is true of E_s, no single theory adequately explains just how "tropo" works although knowledge of it has mounted in recent years. At present, it is generally believed to be connected with turbulence in the atmosphere.

This connection in turn is thought to be associated with weather fronts. It is suspected that fronts may cause the refractive index of the troposphere to fluctuate at random, thereby aiding six meter operators by bending their signals back to earth at varying distances.

Working tropo on six can be an instructive and rewarding experience. Such openings are marked by two fading components, one rapid, one very slow. These are certain indications of tropo propagation, making it easy to identify.

In addition, there are seasonal variations in median signal levels, with strongest signals in summer months. Also, there are meteorological variations, with best signal levels at times when the troposphere contains very warm or very dry air. All these variations add challenge and DX for those who learn how to exploit tropo.

Still another propagation form unrelated to the sunspot cycle is "atmospheric ducting." This phenomenon is certain to puzzle you the first time you encounter it. Signals from distant stations come booming in. But all of the stations are located within a very compact geographical area, sometimes within one small town or single suburb of a metropolitan area. Operators there can hear you as well as you hear them but neither you nor they can work into other areas.

A duct in the atmosphere often lasts many hours and serves the same general purpose as a waveguide. Signals propagated through ducts are strong and steady but always confined to a small geographical area at each end of the circuit. In effect, a duct serves as an atmospheric radio pipeline between two comparatively small areas on the earth's surface.

Ducts form when the refractive index of the lower atmosphere is altered. This is usually caused by the overlay or shifting of warm and cold air masses in such a manner that a non-homogeneous atmospheric "channel" is formed between or beneath them. VHF radio waves are trapped and superrefracted within the duct which guides them along its length and returns them to earth at the opposite end. The strength and range of signals are enhanced. Often they may be heard 1,500 or more miles away—but only in the area at the other end of the duct.

Add these frequently encountered propagation forms to the less common DX possibilities of scatter propagation and, in northern areas, auroral openings, and you have a helpful collection of six meter propagation tools largely independent of sunspot cycles. Proof that these forms of propagation pay off in good DX is apparent in the results of our investigation during the last sunspot cycle decline.

All of the 50 states and 40 foreign prefixes (Tables B, C) were heard/worked during a five-year period in which the mean annual sunspot number shrank from 184.8 to 27.9.

The mean monthly number dropped as low as 14.9, yet E_s-supported DX time alone increased steadily for more than five years after the Cycle 19 peak (Tables A, **D**, **G**, **H**). How to cash in on what lies ahead?

First, you should forget some things. Then you must learn some others you may not know at present. And, if you're a newcomer to six meters, don't feel alone. A surprising number of hams with years of experience on the lower frequencies don't know how to work 50 mhz DX consistently either!

Most of the "rules" you've probably heard about working six meter DX mean little during a sunspot decline. Some of these are based on working F_2 openings and you will not find many of those in the next five or six years.

Also, there are some erroneous ideas around that have nothing to do with F_2. For example, you've probably heard or read that E_s propagation may occur at any time but that essentially it is a daylight phenomenon *peaking at or near midday.*

Our investigation showed clearly that there is considerably *more* 50 mhz E_s DX available *in late afternoon and evening hours* and *much less at or near midday* than theory suggests. Of the 808 band openings recorded during our research, more than 50% of the total occurred after 0000 GMT and 41.83% after 0100 GMT (Fig. 2). These are late afternoon and evening hours throughout the United States.

More openings were recorded between 0100 and 0400 GMT than in any other three-hour period of the monitored day. Daily monitoring periods during the study extended from 1400 to 0500 GMT (7 am to 10 pm MST). At times when the band was open or opening at 0500 monitoring was continued until it closed. The gap in our data for the month of April 1959 is due to moving the study site from Phoenix to Tucson, Arizona. The antenna tower and beam were being erected at the new site in April and no records were kept until the entire antenna installation exactly matched that at the former site.

A move like that—only 100 miles— makes little difference in DX results. But bear in mind that your general geographical location determines to some extent how much E_s DX you may expect. There is a relationship between latitude and E_s propagation. This is apparent in the southern states where six meter operators experience an abundance of year-round E_s openings. But those in north-

ern states have the advantage of auroral openings, so things balance out fairly well regardless of where you live.

Here are 15 suggestions for catching more six meter DX than you may believe possible during a sunspot decline. They have worked for me; I'm sure they will for you:

1. A good, directional antenna is a must. Net forward gain of 8 to 10 db *after* transmission line loss deduction is essential. Use the best low-loss coax you can afford and keep your swr down. You need all the gain you can get.

2. Sensitive, well adjusted receiving equipment is much more important than transmitter power. Whether you use a straight 50 mhz receiver or converter makes no difference so long as the result is efficiency and good sensitivity. Transmitter power is secondary and there's little difference between AM and ssb although ssb buffs like to argue the point. CW is not widely used on six.

3. If, like most of us, your operating time is limited, try to concentrate as much of it as possible between the hours of 0100 and 0400 GMT. Next best bet is 1500 to 1700 GMT (Fig. 2).

4. If you haven't already done so, learn to tune, not talk. If you can't hear 'em, you can't work 'em. Local ragchews are fine but don't attempt to mix them with DX chasing. Much fine DX is missed this way.

5. Get a good *modern* book on vhf propagation and read it. Then reread it slowly and apply what you've learned. But keep an open mind; there's much yet to learn that isn't in the books.

6. If you are not doing it now, form the habit of monitoring WWV daily and make notes of the short-term propagation forecasts it broadcasts hourly at five-minute intervals. They don't apply directly to six meters but you will soon learn that disturbed conditions on the lower frequencies can mean DX on six at times. If you don't know how to read the WWV coded forecasts, write to the National Bureau of Standards, Boulder, Colorado, for information; it's free.

7. Be patient. Don't flip on your receiver, tune quickly across the band and, because you hear no DX coming in, assume the band is dead. A lot of DX is missed this way.

8. Look for E_s openings any time but particularly in summer months. They usually peak in June (Table H) and, on a smaller scale, again in December. South American stations are most frequently worked in spring and fall months. Bear in mind that six meter activity has increased substantially in the West Indies in recent years. Look for them when you hear southeastern states.

9. Check weather patterns and beam in directions where rapid weather changes are reported. And learn how to determine when atmospheric inversions are likely to occur in your area. Such knowledge often aids in working a tropo opening before the less-informed competition discovers it and clutters up the band.

10. In busy band openings, choose an operating frequency that takes you out of the heavy qrm. If you stick with the pack you may experience togetherness but it's unlikely that you will get your fair share of DX with low power.

11. When working an atmospheric duct don't waste time attempting to get into areas you can't hear. It's impossible unless some other form of propagation occurs simultaneously.

12. Replace your transmission line every two years. This is particularly important in industrial, desert and coastal areas. Regardless of quality, coax deterioriates in time. A line that does a fine job when new, may rob you of several precious db a few years later. And, check your antenna at least monthly. Wind, snow, ice, smog, birds and salt air do strange things to antennas.

13. Check all tubes in tube-equipped receivers, converters and transmitters every 60 days and retube throughout annually. Sell your replaced tubes to someone who prefers local ragchewing.

14. Never—*never*—get on frequency with a foreign station. Not only is this bad manners, but some foreign operators are so sensitive about it that they will leave the air if some thoughtless U.S. ham commits this cardinal sin. Try 10 or 15 khz away, if you must, but never zero beat foreign DX.

15. Maintain an accurate log and use GMT, which makes life easier for everybody, particularly so when comparing notes with foreign operators. Keep a record of propagation conditions and effects and report your long-term findings to one of the amateur radio journals. There's so much yet to learn about vhf propagation effects that any serious six meter operator who keeps accurate records may well make a significant contribution to scientific knowledge at any time.

Sunspots? Who needs 'em on six meters? There's plenty of solid DX ahead. Good hunting!

...K7ALE

The DX Desk

With this issue, 73 inaugurates this DX page. We do not go to press with any preconceived format; that will depend largely upon you. We will rely upon the comments and suggestions of those who are concerned enough to make the page a reflection of their own needs and wants.

There is no point in including DX items, expedition news, and the like. Our deadline is so far in advance of publication, that by the time you saw such items in print, they would be as cold as a landlord's heart. Moreover, it is not our intention to pre-empt the function of the many news sheets and bulletins in this field. These are readily available and do a splendid job. We urge you to subscribe to one or more of them. They deserve your support.

What, then, will be our function? Just a short while ago, in New York, Wayne and I discussed this. We came to some definite conclusions. We are convinced that there are several areas in which we DX'ers can play an important role. Of prime importance, however, is the job of bringing DX back to its position of former eminence. Many of us, concerned with the state of DX, due to highly regrettable events in the recent past, have lost our taste for the game, and are sour, more or less, on the whole idea. This feeling of indifference and cynicism must be replaced by confidence and a sense of enjoyment. DX is badly in need of a shot in the arm.

I think that what happened to DX was the inevitable result of our own attitudes. We permitted DX to become a dog-eat-dog rat race, and inevitably this resulted in a debacle. The end began to justify the means. Right and wrong ceased to have any meaning. Expediency, rather than ethics, motivated the quest for contacts. We began to overlook the sharp practices, cutting of corners, and outright dishonesties taking place all around us.

This is not to say that the competitive factors ought to be removed. Rivalry is a healthy part of all endeavors. Competition is very much a part of the world in which we live. But when a hobby assumes the characteristics of intrigue, conspiracy, and even blackmail and intimidation, then it is no longer a hobby; it is more like war! When hams resort to favoritism, granting preferential advantage to individuals and groups, the entire hobby suffers irreparable injury.

A spirit of scrupulous integrity and fair play must characterize every phase of Amateur Radio. We can only be considered as worthy and reliable as our most untrustworthy DX colleague. Unfortunately, we are judged collectively, not as individuals.

73's award, WTW, is being administered very carefully. Every entry is scrutinized as through a high-power lens. We do not intend to allow dishonesty to be rewarded, and will tolerate no hanky-panky. We and our validation affiliates are determined to maintain the highest level of integrity in this award. The penalty for cheating is absolute and irrevocable; disqualification without re-instatement.

We've always felt it was too bad that DX contacts are always so brief. A merely cursury exchange of signal reports, names and locations, followed by the usual QRU, vy 73-tks OM hpe CU agn CL dit dit; this seemed always to fall somewhat short. At this point in time, when nations are seeking ways to establish closer ties of friendship and understanding, DX could be a positive force toward building "bridges of peace" among the peoples of the world. It would be good to develop broader contact, deeper relationship on a personal level, whenever possible. Naturally, we do not mean to imply that an individual should tie up a rare DX station in an interminable rag chew when others are waiting to work him. But certainly we could expand our contacts to a certain degree, seeking ways in which to make friends through radio, rather than mere contacts. We actively solicit suggestions from readers, on this point. There must be many of you who have shared more than the tenuous type of momentary contact which, all too often takes place.

Many foreigners talk about "Ugly Americanism." If we can change the opinions of foreign hams with respect to this over-stressed image, we will be doing our country a great service. Never forget that overseas hams also have families and associates, with whom they discuss ham radio, just as we do. Many minds may be changed, many hearts may be reached. People respond to a spirit of respect and courtesy. And these qualities can be displayed effectively during a qso. Perhaps we hams can do a better job in this field than the diplomats and politicians; a sort of person-to-person program.

The very nature of the science of communications attracts many persons to Amateur

Radio. Non-hams are invariably intrigued with the idea of contacting others via wireless. But I have noticed that the more distant the contact, the more irresistable this attracting becomes. Many times, more often than I can recollect, guests in the shack, only mildly interested in stateside contacts, would become absolutely ecstatic at the sound of a VK, ZL or VR coming through the speaker. There seems to be tremendous incredulity attached to the miracle of overseas communication from one's own home. If we wish to improve the flagging growth rate of Amateur Radio, (and it needs improving,) we can contribute much by exposing more people to the intriguing world of DX. I have used one particular ploy quite successfully. First determining the land of origin of the forebears of my visitor, I would then endeavor, usually not unrewarded, to make contact with the country sought. At the first sound of the familiar tongue from the ancestral motherland one can sense the feeling of tension and excitement. I recall vividly one Hungarian fellow upon hearing an HA answer me with the phrase, "Budapest calling you," practically going berserk. He forced me to promise him right on the spot to help him become an amateur as quickly as possible! At this very writing, I am engaged in teaching code and theory to the young husband of one of my wife's friends. He is so set on getting his ticket that he calls me on the phone every day with questions that stump him; too eager to wait for our regularly scheduled get-togethers. And this came about as a direct result of a 4X4 contact.

How about arranging community DX demonstrations with organized groups: Boy Scouts, Lions, Kiwanis, Rotary Clubs, fraternal organizations, etc. These groups are always on the lookout for program ideas for their luncheons and social evenings. If we can set up portable stations for field days and other events, why not for DX demonstrations. A bit of extra effort on the antenna set-up, and it's a cinch! The potential is incalculable. We might win a bonus in the form of a new unwillingness to condemn us for every malfunctioning TV set, while gaining recruits at the same time. We can contribute a good deal toward the enhancement of ham standing in the community, merely by organizing such activity. Of course, someone might say, "What's this got to do with DX?" Well, whoever said that the only hams who can set up these affairs are traffic net people, or Civil Defense people? Why should not DX'ers do the same?

You have probably gathered that I feel strongly that the emphasis, which has always been on individual achievement, should be tempered with the spirit of group effort as well. You are correct in your assumption. DX has never quite reached that plateau of collective co-operation enjoyed by other phases of the hobby. I see no reason for DX enthusiasts to remain isolated from one another in the exercise of their chief interest. The reason that the other types of activity are so well thought of, is because they contribute toward the welfare of society. We must also find ways of doing this. Well, how may this be done? In point of fact, it is being done, and a lot more often than is generally known.

I can cite example after example. When earthquakes strike, and floods and epidemics, American DX'ers are always on top of the emergency, giving of themselves. I know a doctor ham who spent over 48 hours at his rig, running patches during a recent disaster in South America. The same ham has never failed to arrange for overseas shipments of medicines and serums when they were required. Yet, the newspaper coverage in these

situations has been minimal, or non-existent altogether. If a kid jumps into a lake and saves a dog from drowning; if a hook and ladder company rescues a kitten from a tree, there's always a big hue and cry...picture feature stories, and all. But if a ham, through tremendous expense and eagerness to help, saves the lives of entire communities, or gets word through to the survivors of a disaster, you're lucky if you find it opposite the Lost and Found or the used car ads on page 29.

Why shouldn't DX clubs and individual DX'ers get the kind of publicity they deserve. Or is the Little League more important? Or the Garden Club? Or the local standings of the baton twirlers and tiddly wink team? We desperately need publicity so as to improve our public image. And through DX exploits, we can get it. We merely have to get on the ball and establish liaison with the media. How about it? Again, we want suggestions.

*

Now I come to the piece de resistance. I've left it for last, not because it's a delectable tidbit, but because it's a tough nut to crack, and demands serious thought.

The presently designated sub-band segments, and those slated to be added to the restrictions next November, while they may be well intentioned, are working special hardships on DX'ers, most particularly the CW operators. Because these sub-bands were positioned at the very lowest edge of the bands, it is very difficult to prevent the intrusion of commercials and other interlopers. The anticipated use of these segments has not approached the projected estimates. There is very little activity on these low ends, leading to some wide-open spaces which are very attractive to unauthorized operators. There does not appear to be any active move on the part of our League to request a change from FCC. It appears unlikely that any change can take place without the backing of the League. Since the portions in question are, in large part, the concern of DX'ers rather than others, I feel that we should carry the ball in seeking the changes. We can do this only by concerted action, through letters on both an individual and collective basis. We should request that the sub-bands be re-located well up within the central portions of the previously designated bands. I am not asking you to make "waves." I simply feel that an error in judgement has been made, and that an injustice has occurred as a result, and that we ought to try to do something about it by communicating with the League. I hope you will give this your attention.

*

Well, that's about it for this inaugural page. I hope some of it has been provocative. Please get in touch if you think of an idea which has merit. Remember, I told you that the page will reflect your needs and wants. I have no way of knowing what those needs are if you don't express them.

Next time we'll publish the current WTW standings, new certificates issued, and some pertinent data on the award. By the way, some of the fellows are getting so close to the 300 mark, I asked Wayne to have some certificates made up. We surely would like to see more activity on WTW 40 and 80 meters. The other three bands are getting all the action. How about it, people?

DX Quiz

The Numbers Game

OK, all you DX'ers, let's see how much you remember in the way of country names when faced with prefixes. Score five points for every correct answer. 300-country men should get 100% on this. 250-country ops should get 95%. 200-country beginners should get 90%. Here are the prefixes, you write in the country name. Spelling doesn't count.

1M4	7G1
1S9	7P8
3W8	8F4
4M	9A1
4Z	9F
5B4	9H1
5L2	9K3
5R8	9M2
5T	9X5
5U7	9Y4

The answers to the quiz are on page 117. Don't sneak a look until you've done your very best.

NEW BOOKS

Fairchild Catalog

The 1969 *Fairchild Semiconductor Discrete Device Condensed Catalog* is now available. This book contains a complete listing of Fairchild discrete devices, from diodes to FETs to power transistors.

Devices are listed numerically within specific categories enumerated in the table of contents. All are available from your Fairchild Distributors. The catalog contains a list of all the distributors who have these items on the shelf for immediate sale. It contains a numerical index as well as a break-down of the various devices.

Free from Fairchild Semiconductor, 313 Fairchild Drive, Mountain View, Calif. 94041.

New Semiconductor Handbook

Motorola has announced publication of the Semiconductor Power Circuits Handbook, containing the latest information in power circuit design. Prepared especially for users of power transistors, thyristors, rectifiers and zener diodes, this 264-page manual includes many designs being published for the first time. Some 150 new circuits have been specially designed, constructed and evaluated in Motorola's applications test laboratories to ensure design-improving performance.

The information-packed "how-to-do-it" handbook is divided into six chapters that cover the major application areas of interest to semiconductor power device users – (1) motor speed controls, (2) inverters and converters, (3) regulators, (4) static switches, (5) audio and servo amplifiers, and (6) miscellaneous thyristor and transistor switch applications – covering virtually every type of power application.

Approximately 270 illustrations complement the text, providing detail circuit illustrations and waveform diagrams. Complete bibliographies are also included for each chapter.

Copies may be obtained by sending check or money order for $2.00 per copy payable to Motorola Inc., at Box 20924, Phoenix, Arizona 85036.

What Am I Eating?

Can you guess the food from the list of the ingredients? "Contains water, coconut oil, non-fat dry milk, tapioca flour, lactic acid, mono and diglycerides, citric acid, locust bean gum, artificial flavor, quar gum, carrageenan, potasium sorbate and artificial color." What am I eating? See page 136.

Whipping "Two" Mobile

Alton E. Glazier, K6ZFV
3154 Jordan Road
Oakland, California 94602

The need for a better two-meter antenna for mobile use was the reason for trying both five-eighth and three-quarter whip base-loaded antennas. From the schematic, it will be noted that two antennas were tried out, one with a series coil, and the other with a grounded coil with a tap for impedance matching.

The parts required are:

1. Connector, of a type to be determined by individual need. However, in the grounded coil configuration, be sure to use a connector which makes a positive ground connection.
2. Plastic pill vial, size 1-1/8" O.D. and 2-3/4" long, which can be purchased at your local drug store.
3. #14 enamel wire
4. 3/8" dia. brass rod stock, 2" in length
5. 2 ounces of casting resin, catalyst (4 drops per ounce) and coloring if desired. Dye will give a transparent effect, pigment opaque. These items can be obtained from most hobby shops.
6. 1/8" diameter metal rod, 53" long, for series coil antenna.
7. 1/8" diameter metal rod, 48" long, for ground coil antenna (these rods are much longer than necessary).

Construction

Take the 3/8" diameter brass rod. From one end, drill a 1/8" diameter hole 1¼" deep. Measure 3/8" from this end, and at right angles to the previous hole, drill and tap for a 6/32" bolt. Measuring from the same end 1", drill and tap for a second 6/32" bolt. On the opposite end of the brass rod, drill a hole ¼" deep, just large enough for #14 diameter wire.

The series coil is wound on a ¼" diameter form, using #14 wire, 11 turns. The coil length is 1½". At one end of the coil, bend the #14 wire at a right angle, then clip off at 3/8". At the opposite end, bend #14 wire to a right angle, and clip at a distance of 1½". Scrape enamel off both ends. Solder the short end to the brass rod. Take the pill vial, and starting with a small drill, drill a hole in the center of the bottom. Slowly increase this diameter to 3/8", being careful not to crack the plastic.

Insert the brass rod with the coil attached into the open end of the pill vial and slip it through the 3/8" hole so the rod will protrude from the bottom of the vial for a distance of 1-3/8". Slip the coaxial fitting over the long end of the wire, and insert enough of the fittings so that it will be into the vial,

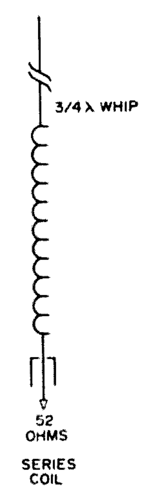

Fig. 1. Coil encapsulated in plastic pill vial.

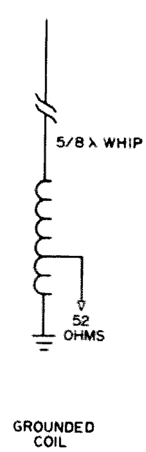

Fig. 2. Three quarter wave whip with series coil.

but be sure the connector will be clear to operate.

Now center the brass rod and keep it parallel with the plastic container and the coaxial fitting. Solder the long wire to the coaxial connector. Check once again to be sure the fitting, the plastic vial and brass rod are all vertically in line.

In order to keep the plastic from escaping, and to keep the brass rod in line, it may be helpful to use either putty or a fast-drying glue. With the vial upright (coaxial connector up) you are now ready to pour the casting resin. This container will require two ounces of casting resin and eight to ten drops of catalyst. If coloring is desired, mix either pigmented color or dye with the resin before adding the catalyst. See the manufacturers instructions for details on mixing. Carefully pour the resin into the vial, and let it stand for twenty-four hours.

The second antenna is made in very much the same manner, except the coil is wound on a 5/8" form. The total number of turns is six, and the spacing between turns is the width of the wire. The end opposite the brass rod is soldered to the outside material of the coaxial fitting. A piece of flexible #16 wire is brought up through the connector and is tapped to the coil two turns from the grounded end.

To prune these antennas to frequency, use a piece of expendable wire the same diameter as the final whip. Insert into the opening of the brass rod and secure with 6/32" bolts. Insert a standing wave bridge in the coaxial line, tune up the transmitter, and check the swr, which should be fairly high. Shut off transmitter and clip approximately ¼" from the top end of the antenna. Turn on transmitter, retune, and check swr. Keep using this procedure until swr is at minimum. After finding the proper length, remove the whip and use this measurement for the permanent antenna, which will be made of spring metal. For best results, be sure this pruning procedure is done at the permanent position of the antenna on the vehicle.

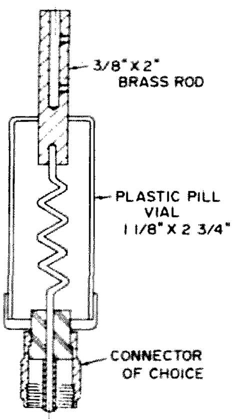

Fig. 3. Five eighths wave whip with grounded coil.

The tests were conducted over as flat a terrain as possible, trying to preclude the possibility of reflections. Three different test sites were used. The reference antenna was a quarter-wave 19" whip. All tests conducted showed the long antennas to give better signal strength and less mobile flutter both on transmit and receive.

It would appear that possibly the three-quarter wave antenna has a higher angle of radiation than the five-eighths wave antenna; however, not a sufficient number of tests were made for angle of radiation to be conclusive. It would also appear that there was no advantage in one method of coupling over another. The number of tests made was thirty. Although S-meter readings in most receivers are rather meaningless, they do give us a relative indication as to strength. The thirty tests made showed an average increase of over one S-unit. The standing wave ratio of the various antennas was as follows:

Quarter-wave, 1.3 to 1
Five-eighths wave, 1.1 to 1
Three-quarter wave length, 1.2 to 1

The antenna was located on the roof of a station wagon. The transceiver was an SR-42, and the standing wave bridges were a Mars and a Calrad.

Although it is never a good idea to encapsulate the antenna coil, in this case the inductance was so small that no apparent differences were noted between this type of construction and air-wound coils. It was apparent the mechanical advantages were well worth any slight degrading.

Design of UHF Tuners Using Silicon Transistors

Suleyman Sir
Communications Applications
Care of Fairchild Semiconductor
313 Fairchild Drive
Mountain View, California 94041

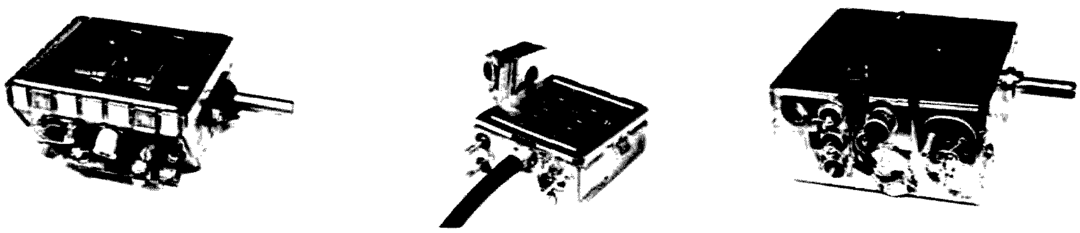

FIG. 1. PHOTOGRAPH OF THREE UHF TV TUNERS IN THE MARKET.

Since the 1964 FCC requirement that all television sets provide UHF reception, manufacturers have spent considerable time and money on the design and development of economical UHF tuners.

Size, performance, cost and reliability are the objectives in tuner design. The introduction of small screen portable sets has made the dimensions of the tuner a decisive factor in design. A miniature UHF tuner is attractive in that it may be used in all sets, but miniature units are not efficient in performance and are expensive to manufacture. A larger tuner, for example, 2.7" x 1.3" x 2.8" is more efficient, easy to manufacture, but often will not fit in small sets. The size problem is solved by manufacturing different size tuners, but this requires additional manufacturing lines and increases inventory cost.

Transistorized UHF TV tuners are superior to tube types because they can be manufactured in small sizes, are more efficient and stable, and do not require periodic maintenance while providing a longer life span. Figs. 1a, b and c show three sizes of UHF tuners presently in use. The first two can be used in small screen portable sets while the larger is suitable for console sets.

Description

The UHF TV tuner described here was built to demonstrate the capability of the new UHF oscillator device, SE3005, and to provide guide lines for its use in tuner design. After the basic size of the tuner is established the design problem would be to assure optimum performance, simple construction, reliability, low cost and ease of manufacturing. Fig. 2 shows the finished tuner. The two compartments on the left are double tuned passive *rf* pre-selector cavities, while the third, on the right, is the local oscillator cavity. The center section also houses the mixer diode and associated components.

RF Sections

The pre-selector *rf* cavities have capacitively tuned lines. The lines and the cavities are self resonant at 1,000 MHz. The lines are selected by an empirical method, mathematical analysis is difficult because the frequency of operation spans from the point where simple transmission line theory can

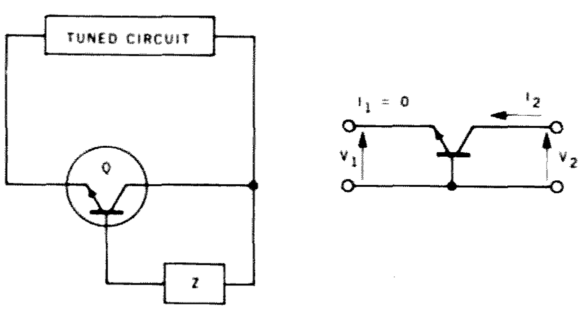

FIG. 1A. BASIC TRANSISTOR OSCILLATOR CIRCUIT.

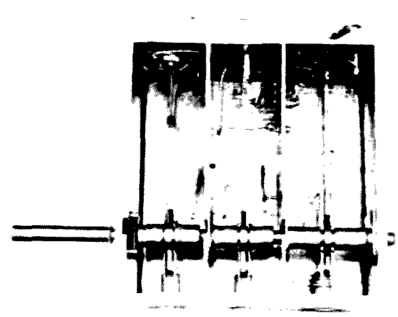

FIG. 2. PHOTOGRAPH OF TOP VIEW OF A UHF TUNER.

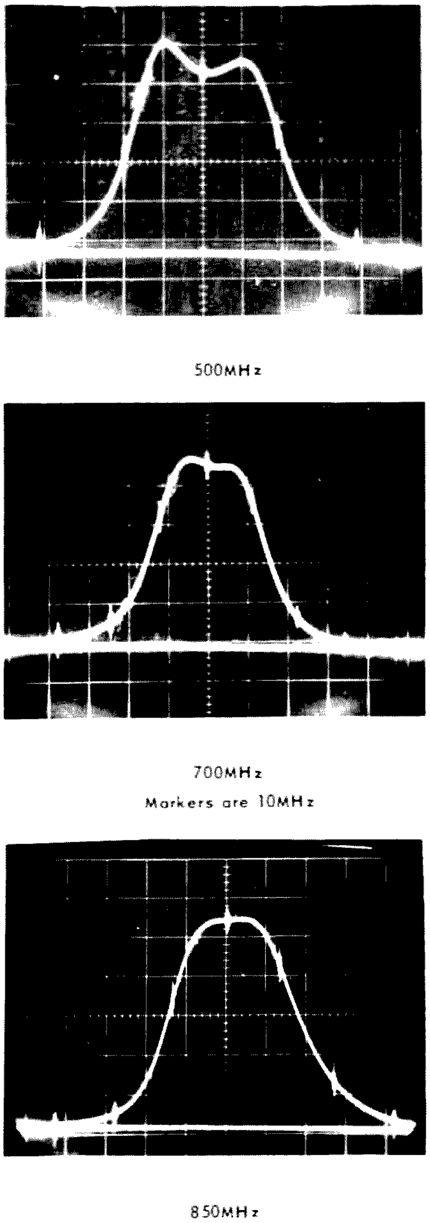

Fig. 3. Q_L of the tuner at three different frequencies.

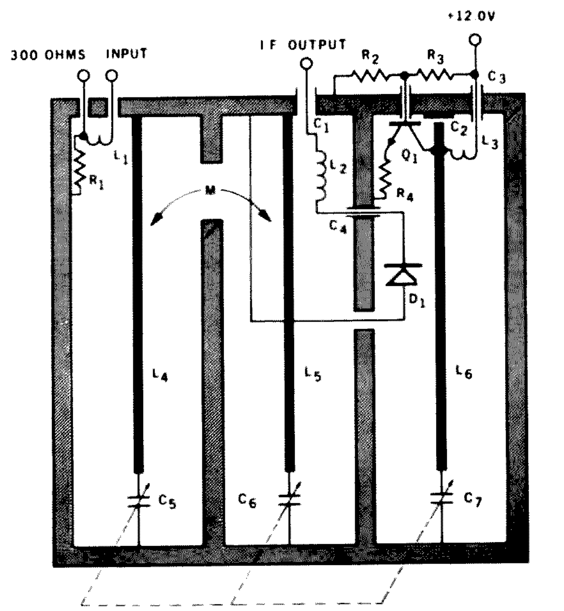
be applied (890 MHz) to frequencies where lumped inductance (470 MHz) is effective. The loaded Q_l of the cavities are high at the high frequencies and lower at the low frequencies. The calculated unloaded Q_U of the cavities is about 1,500 at 470 MHz and 1,800 at 900 MHz. The Q is considerably lower at 470 MHz because the variable capacitor's sliding contacts acts as a signal path at this frequency. The bandpass response of the pre-selector cavities is shown in **Fig. 3** at the indicated frequencies. These cavities are coupled by a 1.3 x 1.8 cm window. The location and the dimensions of the window are determined by the bandwidth requirement and the location of the capacitor rotor shaft.

The 300-ohm input is inductively coupled to the cavities. The lines in *rf* sections are 2.4" x 0.4" x 0.05" silver plated brass. One end of each line is welded to the cavity wall, while the other is anchored with a ceramic stand-off. This method of mounting helps to prevent microphonics.

Oscillator Section

A common-base oscillator was used. The SE3005 has sufficient internal feedback capacity to sustain oscillation across the UHF TV band. Therefore, additional external feedback was not used. The schematic of the oscillator circuit is shown in **Fig. 4**. The transistor base was *rf* grounded through capacitor C_1. The collector tuning tank circuit consists of the transistor collector capacitance, line L_6, and variable air capacitance C_7. The transistor collector was shunted with capacitor C_2 for the desired frequency of oscillation and stability. Capacitor C_2 is a ceramic disc; one side of it was soldered to the cavity wall and line L_6 was soldered to the other side. Therefore, C_2 acts as support to one end of L_6 while the other end of L_6 was supported by a ceramic column. Tying down L_6 in this manner prevented the possibility of mechanical vibration.

The oscillator was biased for minimum



R_1 = 15M	C_4 = 50 pF. Tubular
R_2 = 3.3k	L_1 = Matching network for 300 Ohms
R_3 = 10k	L_2 = 5T, 0.15" ID. #24 Wire
R_4 = 330 Ohms	L_3 = 10T, 0.10" ID. #24 Wire
C_1 = 500 pF. Tubular	L_4, L_5, L_6 = See text
C_2 = 10 pF. NPO	Q_1 = SE3005 Fairchild
C_3 = 1000 pF. Tubular	D_1 = FH1100 Fairchild

FIG. 4. A TYPICAL UHF TV TUNER SCHEMATIC.

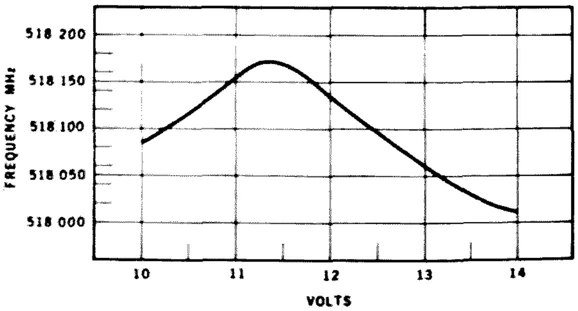


FIG. 5. FREQUENCY VARIATIONS WITH VOLTAGE.

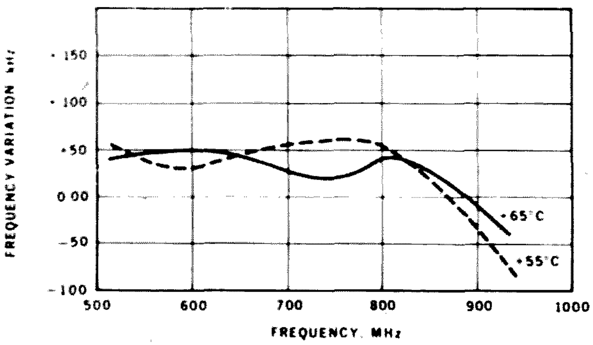

FIG. 6. FREQUENCY VARIATION WITH TEMPERATURE.

frequency drift. Fig. 5 shows frequency drift versus bias voltage while Fig. 6 shows the frequency stability with temperature change.

The oscillator cavity was built larger than the *rf* cavities for ease of soldering the transistor and its associated bias components. The transistor leads were kept as short as possible because long leads have an adverse effect on oscillator performance.

Mixer Section

The mixer section consists of a Hot Carrier Diode (FH1100), an inductance (L_2), a capacitor (C_4) and two pick-up loops. One loop is used in the local oscillator cavity and the other in the mixer cavity. The mixer cavity works as follows: The incoming *rf* and LO signals are coupled into the non-linear diode element; the LO signal forces the non-linear diode element to become a time-varying active network. Under this

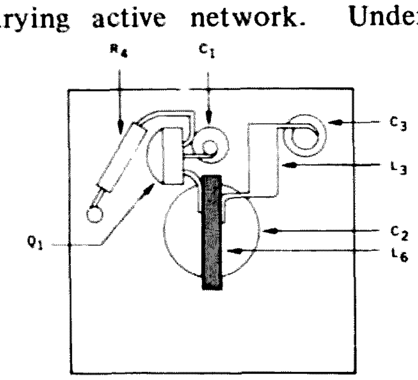

FIG. 7. COMPONENTS LAYOUT FOR OSCILLATOR.

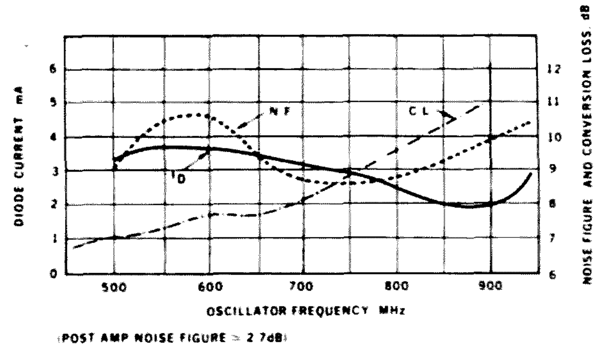

Fig. 8. Diode current, noise figure, and conversion loss of tuner.*

condition the diode generates harmonics; either the sum or the difference of LO and *rf* signals is extracted from the output of the mixer diode and is called the *if* signal. In UHF TV tuners, the LO signal frequency is above the *rf* signal. Until 1966 point contact diodes were used as mixer diodes in UHF TV tuners but Hot Carrier Diodes are seeing increased usage because of better reliability, better V-I characteristics, low noise figure amd low conversion loss.

The inductance L_2 and capacitance C_4 provide a low-pass filter for the *if* signal and provide a matching network between the diode output and the *if* amplifier. L_2 and C_4 are self resonant at 80 MHz for image suppression. The mixer diode current is adjusted by changing the size of the pick-up loop in the oscillator cavity. The magnitude of the diode current depends on loop area and its proximity to the line L_6. The location of the loop was chosen to prevent overloading the oscillator. Since the location of the loop would change the load reflected to the transistor, it could cause the oscillator to stop. Fig. 8 shows the diode current, noise figure and conversion loss variations across the UHF TV band for one diode loop setting. A smooth current output is desired since excessive variations impair overall reception. Forward biasing the mixer diode will affect the noise figure and output current; however, an optimum bias setting is difficult to establish because the oscillator output is not constant across the UHF band.

Conclusion

The tuner described here performs with an output that was not appreciably affected by variations in transistor parameters. Since mass production was not the aim, life expectancy or durability of the cavity under use was not analyzed.

Adjusting FM Deviation

The proper adjustment of the deviation control is important for good FM communications. If it is too low, the audio at the receiver is also low. If it is too high the over-deviation will bring you reports that though your signal is strong, it breaks up when you talk.

Test instruments for measuring transmitter deviation cost upwards of $250. There is, fortunately, a shortcut method for deviation measurement using just an FM receiver and an ac voltmeter (or oscilloscope).

To adjust deviation using this method you must use a receiver with the appropriate bandwidth. The economy priced monitor receivers are of no use here. If you want to use a narrow band ± 5 khz system, you must use a receiver with this bandwidth. If your system contains both wide and narrow band units, adjust all transmitters for narrow band operation. This will cause slightly reduced audio in the wide band receivers, but will provide much better overall performance.

Most commercial units such as Motorola, GE, etc., have power supplies which will allow the transmitter and receiver to be used simultaneously for short periods of time. Refer to the schematic to see how this can be accomplished. In this way you can use your receiver to check the deviation of your associated transmitter.

Connect the ac voltmeter or scope across the speaker terminals. Substitute a five watt resistor for the speaker if you can't stand the noise. Apply a 1 kHz tone to the transmitter or whistle steadily into the mike if an audio oscillator is not available. Slowly advance the deviation control from its lowest position (with the transmitter turned on) and watch the ac meter.

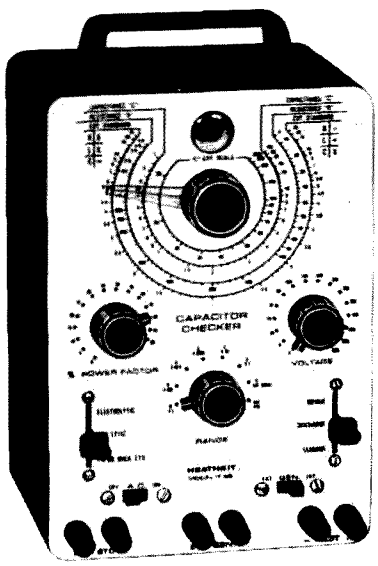
As you increase the deviation you'll see a fairly linear increase in the receiver audio level, followed by a flattening out, and then, as you go outside the passband of the receiver, the audio level will fall off and the noise level will increase. This is just what happens when an over-deviated signal is received by another FM mobile.

Repeat the adjustment several times, paying particular attention to the point at which the linear rise just starts to flatten. This is the point at which the deviation control is properly set.

I've used this system to set deviation on many occasions and have been amazed at its accuracy when compared against properly calibrated instruments.

Review of Heathkit IT-28 Capacitor Checker

Eugene Fleming, WØHMK
328 Gunnison Avenue
Grand Junction, Colorado 81501



A careful scanning of most of the electronics magazines from the early '50s to the present has brought to light some interesting capacitor checker circuits, but none of the construction articles on these instruments boasted a range from picofarads to hundreds of microfarads.[1,2] This is the range encountered by even a casual builder.

Examination of the specs. of commercially available capacitor checkers revealed that most of them do not cover the wide range of values needed by the experimenter and builder. The one that is satisfactory has a price tag that disqualifies it.

When the announcement of the revised Heathkit Capacitor Checker IT-28 recently appeared, I immediately began to devise means to get the XYL out of the house long enough for me to pick the lock on the piggy bank.

Manual

An outstanding feature of the kit is the three page circuit description included in the construction manual. Simplified schematics are used to clarify the theory of operation. Any ham with elementary knowledge of test instrument circuits will find these pages enlightening reading even if he has no intention of building the tester.

In addition to the standard Heathkit step by step instruction and pictorials, there is an easy to read two page schematic of the instrument at the back of the manual. Included on the schematic are operating voltages expected at the tube sockets, which are indispensable for trouble shooting.

Circuit

The big surprise came when the power supply schematic was examined. The half wave vacuum tube rectifier is unusual for new equipment in this time of semiconductors. A little reflection indicates that there is about 1500 PIV in the circuit, which inexpensive diodes do not handle.

The heart of the IT-28 is the bridge circuit, which uses the 6E5 "eye tube" as an amplifier and null indicator. Three resistance and three capacitance standards are included in the instrument. Driving voltage for the bridge is provided by a transformer which supplies 60 Hz ac. Provision is made for use of external driving voltage of up to 10 kHz. There is also provision for connection of standard resistance, capacitance, or inductance for comparison with a component of unknown value connected to the "Test" posts.

Construction

Construction time for a nearsighted, butterfingered technician was approximately 9 hours.

Wiring is greatly simplified by a ready-made harness that already has the insulation stripped from the ends of the wires. Components are uncrowded for the most part.

Most of the electronic components are mounted on a conventional chassis using

tube sockets and terminal strips. Controls are bolted to the front panel. A sizable portion of the construction time is consumed in the interconnection of the panel and chassis.

The hardest part of the whole operation is mounting the line cord strain relief insulator.

Even the beginner should have little difficulty getting this instrument to operate, for construction is straightforward.

Operation

With 8 front panel controls, this instrument might at first glance appear a complicated knob twirler's delight. It does not turn out to be nearly as complicated as it looks. Care is required to be sure the range, bridge-leakage, type, and power factor controls are properly set before beginning to try to get the eye tube to open.

Anyone with vtvm available will find resistance measurement easier with it than use of resistance ranges on the IT-28, even though these ranges are quite usable. The 200 ohm, 1% resistor included for calibration of the instrument also comes in handy for calibrating the vtvm.

The capacitance ranges are a real delight to those who salvage parts from defunct equipment, but who do not want the "junk box" cluttered with components in doubtful condition. These ranges will serve the builder or repairman well as a tool in positively indicating a capacitor's condition.

For best results in checking capacitors of a few tens of pf, it is best to use an external generator connected to the posts supplied for the purpose. A check indicated the frequency of the external signal is not as important as the ability of the generator to supply adequate voltage to the low impedance of the input. A 1000 Hz tone taken from the 16 ohm output of an amplifier running at high gain made the null much sharper than did the internal 60 Hz. It was possible to measure capacitance of a pair of twisted wires.

The "Mini-lytic" function of the "Type" switch will be most useful to those who work with transistor circuits. Who doesn't, these days?

The "Electrolytic" function also provides a test of "power factor" of the capacitor. "Power factor" is the cosine of the angle by which the applied current leads the voltage in a capacitor. Use of a capacitor with a high power factor can seriously degrade the performance of filter, bypass, or coupling circuits.[3]

The "Leakage" position of the "Bridge-Leakage" switch will test quickly the condition of all three types of capacitors, with differences in type taken care of by proper setting of the "Type" switch.

Since the instructions specify that the upper operating frequency of the IT-28 is 10 kHz, it is inconceivable that the comparator range is useful for checking any inductance other than those used at audio frequencies. If much work using this range is anticipated, precision inductances of 1 henry and 100 milahenries should be acquired. Turns ratios of those old transformers cluttering up the "junk box" can also be determined.

Conclusion

For the ham builder who has a vom or vtvm, a grid dip meter and access (maybe at the corner drug) to a tube checker, the IT-28 is recommended highly as the next piece of test equipment.

Specifications:

Test Circuit

AC bridge powered from internal 60 hz or external source.

Ranges:

Capacitance–10 picofarad to 1000 microfarad in 4 overlapping ranges, one range for comparison with external standard.

Resistance–5 ohms to 50 megohms in 3 ranges. One range for comparison with external standard.

Inductance–One range for comparison with external standard only.

Power requirements

115 or 230 (nominal) volts ac 50/60 hz. 30 watts.

Internal power supply

Half-wave rectifier.

Tube complement

6E5, 6AX4, 6BN8.

Controls

Bridge balance, power factor, test voltage, range switch, type switch, bridge-discharge-leakage switch, on-off, int.-ext. bridge power.

Size

9-5/8"x6-5/8"x5"

Weight

5 pounds.

How to Convert Your Receiver for 6 Meter Reception Without Really Trying

...a chapter in the life of a 75A2...a story that asks the question, "Will Collins recognize this receiver after he's done with it?"

Robert L. Grenell, ex W8RHR
3926 Beech Street
Cincinnati, Ohio 45227

Those of you who are fortunate enough to have a 75A2 have undoubtedly been waiting with bated breath for someone to write an article on a six meter conversion. This is your lucky day, because you can now resume normal breathing. You can also prepare to dig into the innards of your receiver.

One feature I particularly wanted to incorporate in my revision of the 75A-2 was the convenience of internal capability for 6-meter coverage. The 75A-2, being a double conversion receiver with a crystal-controlled first oscillator, lends itself to this treatment very nicely, since the front end is really a multi-band crystal-controlled converter. I even had an extra bandswitch position to play with, since it originally covered the lamented 11 meter-band, tuning 26 to 28 MHz. In order to keep the bands in ascending order, I decided to convert the 11-meter band to 10, and 10 meters to 6. The first step entailed only plugging the 10-meter crystal into the 11-meter socket and repeaking the coils. Nothing much to that.

Now, the fun began. First, there were a number of decisions to make and considerations to be met. The *rf* stage uses a 6AK5. Let's face it-6DC6's, 6BZ6's and 6GM6's notwithstanding, you can't find a better tube than the 6AK5 for low noise, high gain, and efficient performance over a wide frequency range. Futhermore, we're talking about 6-meters, where atmospheric and thermal noise are the limiting factor. Only in cases of the grossest misdesign or bad tube choice will the front end noise ever be a serious problem. The 6AK5 is still in excellent shape at 50 MHz. So, I decided to leave the *rf* stage alone-except for the coils. The 6AK5 is just out of vogue, but it's far from outmoded. Obviously, the noisy 6BE6 mixer would have to go, but first I wanted to get things perking on 6 so I could try some substitution tests. I was not particularly impressed with the

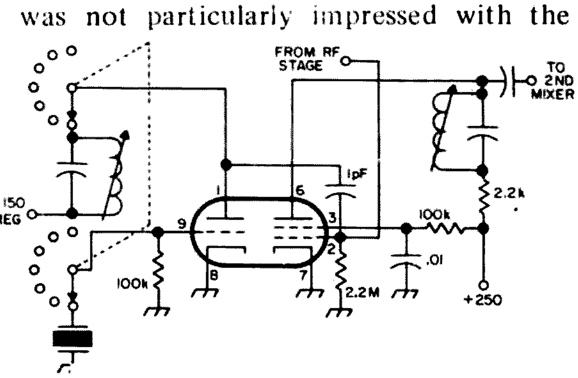

Fig. 1. Mixer-oscillator conversion suitable for adding 6 meter coverage as installed in the Author's 75A2. It is also recommended for improving the performance of older receivers. It features low noise and excellent performance over a wide frequency range. The 6EA8 offers a conversion of 4000 microhmos.

range of tubes which I could try in this application, but, as you will see, circumstances forced me to an excellent choice.

I now began to physically attack the receiver. The 10-meter coils were pulled, rewound for 6, reinstalled, and peaked with a grid-dipper. I plugged in a 55.455 MHz overtone crystal. Nothing happened. It wouldn't oscillate. It seems that the Collins 12AT7 multivibrator oscillator circuit required more crystal drive than I could get at that frequency. Major surgery was called for. Now I had to redesign the oscillator as well as the mixer. However, the problem of choosing a mixer was solved. A quick survey of the tube manuals, literature on new equipment, and back issues of 73 revealed that my best choice would be the 6EA8, a triode-pentode mixer-oscillator closely related to the 6U8. This nifty little bottle is designed for VHF television applications, and provides a conversion transconductance of 4000 micromhos compared to only 475 for the 6BE6—which is a noise generator above 20 MHz. It has excellent noise characteristics, and I felt sure that 6-meter performance would be good, and 10-meter performance much improved.

Everything was stripped from the 12AT7 and 6BE6 sockets. The mixer-oscillator circuit shown in Fig. 1 was built up using the 9-pin socket. The only other change necessary was to reduce the value of the VR tube dropping resistor from 2500 to 2000 ohms. I plugged in the 6EA8 and peaked up the oscillator coil. It took off at once. I realigned the whole front end and started listening. Results were beautiful. Without the masking noise of the 6BE6 I discovered how noisy my location is! The extra gain and low noise characteristics of the 6EA8 really shine on 10 and 15. Signals average 6 to 8 db farther out of the noise than before the conversion. On the lower bands, there's little difference, predictably, except during opening and closing on 20, when the low noise factor and extra gain help greatly. Performance on 6 is excellent. The noise figure is slightly better than that of the familiar Handbook converter using 3 6CW4's! If that seems hard to believe, remember that a converter running into a receiver is subject to matching problems, and that every stage means that more noise is generated in the receiving system. The use of converters as we are accustomed to them is convenient and economical...but it's certainly not optimum!

Six-meter ground-wave reception is solid for a 100 mile radius, and I regularly hear stations in Michigan, Tennessee, Pennsylvania, and West Virginia—as well as the expected Kentucky and Indiana. Although I don't have the equipment necessary to make a good evaluation, receiver noise is well below thermal and atmospheric noise. I hear everything anyone else in the area hears, and more than some. Birdies are not evident, another advantage of an internal arrangement over a converter set-up. The conversion was completed by making the appropriate changes in MHz dial calibration and the band switch index. A conversion of this type is easy and suitable for any receiver having a crystal controlled front end. Even if you don't have an extra band (like 11 meters) to play with, you can add a position on your bandswitch, if you're the ambitious type.

The whole thing goes together easily, is uncritical, and stable. It's nice to be able to flick up to 6 without having to wade through the usual rat's nest of wires, and there's absolutely no compromise between convenience and performance—both are improved! The only thing I don't like is that empty socket that used to hold the 6BE6 mixer. It just sits there begging to be used. Let's see now... what could we put in there...?

...W8RHR

Monitor 2

Alton E. Glazier, K6ZFV
3154 Jordan Road
Oakland, California 94602

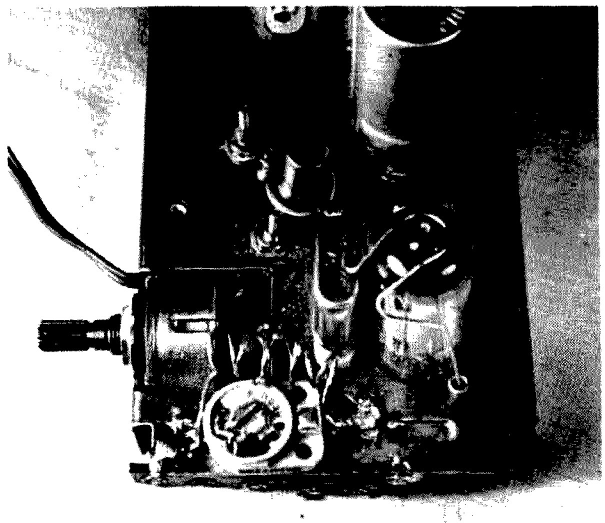
The need for Monitor 2 arose from the many hams who want to monitor two meter repeaters while still leaving their main equipment free, and possibly is an answer to 24-hour-a-day emergency listening. It was decided to make the project as easy as possible, with high reliability and low cost.

The basic receiver is the old standby, the five-tube ac/dc broadcast radio (12BE6, 12BA6, 12AV6, 50C5 and 35W4), purchased from most catalog houses or drug stores for about $10. Most of these imports are hand wired, and this is recommended for ease of conversion.

The major change is at the converter (12BE6). The *if*, second detector, and audio stages are left as is. Remove the variable capacitor, antenna coil and oscillator coil. This will give you the space needed for the crystal oscillator tube and components. The oscillator is the one described by Frank Jones, W6AJF ("The Overtone Harmonic Crystal Oscillator," *CQ Magazine*, February, 1963). This is an excellent circuit, and makes possible this simple conversion.

Remove everything from pins 1, 2, 6 and 7 from the 12BE6. Bypass filament pins 3 and 4 to ground with a .002 capacitor. Mount L-2, C-2 as close to socket as possible. One side of L-2, C-2 connects to pin 7. The other ends of L-2, C-2 connect to ground. Connect a 27 K ¼ watt resistor and a 4.7 pf capacitor from pin 1 to ground. Dress this resistor close to the chassis. This completes the mixer conversion.

The oscillator uses a 6CW4. Although the filament current is slightly different from the rest of the tubes, no harmful effects have been noted. Trace the filament series string and find that filament lead which goes to ground. This will vary according to the manufacturer. Remove from ground, and install a choke made up of ten turns of hookup wire 1/16" in diameter. From the previous filament, connect to pin #12 of Nuvistor socket. Also bypass to ground with a .002 capacitor. Ground pin #10. This completes the filaments. From pin #8, connect a 4uh choke and a 10 pf capacitor. Ground the opposite ends. From pin #4, install a



The Monitor 2.

100K ¼-watt resistor, also a lead to crystal socket. The opposite end of resistor and crystal socket go to ground. From pin #2 connect a lead to top of L3 and C3. Also connect lead of 4.7 pf capacitor. The opposite end goes to pin #1 of 6BE6. At the bottom of coil L3 and C3, bypass to ground with a .002. Also connect a 4700 ohm resistor. The opposite end of resistor goes to nearest B-plus lead. This completes the oscillator circuit.

For those who live within line of sight of the repeater, this simple mixer-oscillator should provide enough sensitivity. For an antenna, connect a piece of insulated wire from the top of L-2, C-2 to back of receiver, then to a wire rod. Because the receiver is hot to ground, be sure to use insulated sleeving over antenna. The connecting wire and rod should measure 38" overall. It is interesting to note that this directly coupled antenna outperformed any attempt to use an outside ground plane.

For those not in line of sight of the repeater, the following *rf* amplifier is very worth while. The *rf* amplifier is quite straightforward. Just be sure antenna coil is shielded from the mixer coil or at least at right angles. The transistor was taken from the *rf* section of a junked RCA FM receiver. Most PNP vhf transistors should work quite

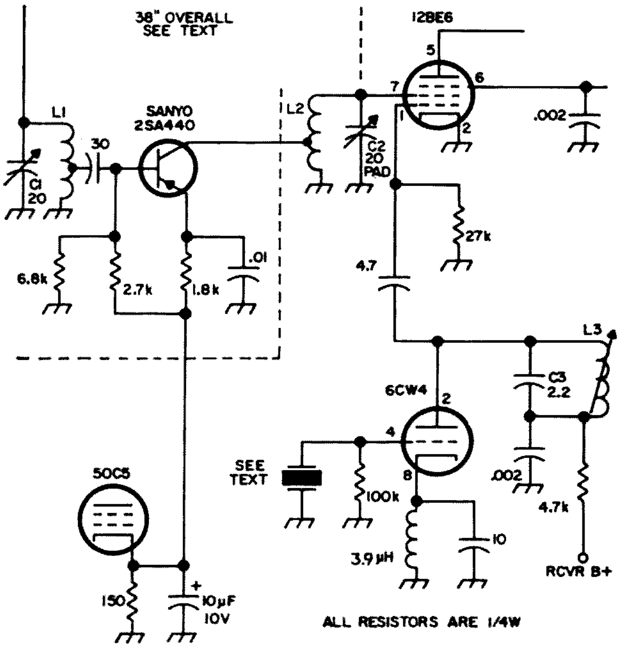


Fig. 1. Complete diagram for Monitor 2.

L1—5T, ¼" diameter, 3/4" long, airwound center tap.
L2—3T, ¼" diameter, 3/4" long, airwound center tap.
L3—4T, ¼" diameter, ¼" long, Miller #4300.
L4—3.9 uh choke.

well, and perhaps a FET would be better. The power for the *rf* amplifier is taken from pin #1 (cathode) of the 50C5. Be sure to use a cathode bypass capacitor if it is not already present. Ten to twenty-five mf, ten volt.

The crystal is a third overtone, and is lower in frequency than the receive signal. The reason for this is that the receive signal that I wanted to monitor was at 145.100 mhz. Due to the fact the *if* frequency is 455 hkz, this puts the image on the lower end of the two-meter band. In one month of monitoring, no image signal has been heard; however, if the receiver is to be used in the upper end of the band, perhaps the crystal frequency would be better on the high side. This will depend on the activity in your area.

As to the crystal frequency, after it has been multiplied three times, it must be 455 khz different than the receive signal or thereabouts. If a surplus crystal is found near enough in frequency, the *if* transformers can be shifted to allow for some difference, for 455 khz is the design center of the *if* transformer, and it can be moved up or down in frequency. For example, in the author's receiver, the crystal used (surplus) is marked "48.222 MC." After being multiplied, it gives a frequency of 144.666 mhz. The frequency of the monitored repeater is 145.100 mhz; therefore, the *if* frequency is 433 khz. The *if* transformer has been shifted 22 khz.

Tuneup

First adjust L-3 in or out until oscillator oscillates. This can be determined by your regular receiver tuned to the multiplied oscillator frequency. Then check for repeater activity. If on, tune first *if* until repeater is heard, then peak for maximum, then the same for second *if* transformer, then peak C-2 for maximum and C-1 for maximum (if used).

Conclusion

This receiver has given excellent reliability, has a narrow bandpass, no drift problems, small in size (5" x 8" x 4"), light weight and low power consumption. By their basic design, any ac/dc radio is dangerous when out of its case. Be sure to remove power cord before working on chassis. In tuning, use insulated tools, stand or sit on insulated material.

Any of the conventional noise clippers or squelch circuits may be used if desired.

...K6ZFV

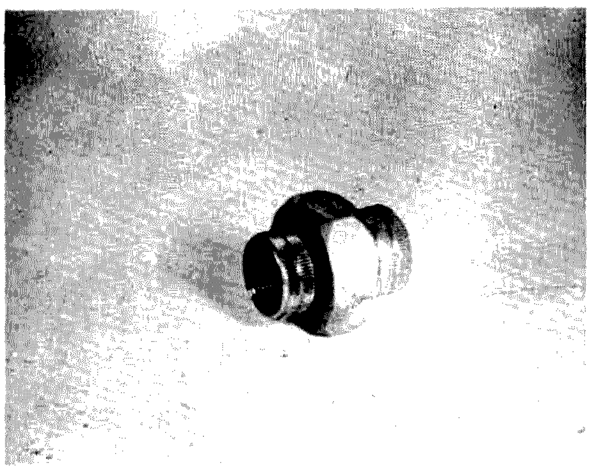
40, 20, and 2

Thomas Niedermier, WA8IYL
Box 163
New Washington, Ohio 44854

The tower here that supports the two meter ground plane and twenty meter inverted dipole also serves as a forty meter vertical. It consists of thirty three and one half feet of one and one quarter inch pipe insulated at the top and bottom with a dielectric pipe union. These are available at most plumbing stores. *This type pipe connector makes it easy to put several antennas on one pipe and insulate them from one another. These dielectric unions have a built in spark gap which makes the whole thing a fairly good lightning rod.

The two meter ground plane is constructed on a one inch pipe cap as shown in the Antenna book. The inverted dipole is also right from the book. I have a twenty meter dipole, but one can be put up for any band.

A five foot section of one inch pipe was used between the ground plane and the vertical here, but any length can be used to get the height you want. Although too much height might get you into support problems.



The dialectric pipe union.

The inverted dipole can be used to help support the tower against prevailing winds.

A hook is installed just below the ground plane for hanging the dipole.

The coax from the top two antennas cannot be run down the vertical, but should be run off at as near a right angle as possible. All three antennas are fed with 52 ohm coax, but each must have its own feed line.

The antenna is held to the side of the house by two snap-in wall mounts from Allied Radio. The weight of the whole thing rests on the bottom dielectric union and the ground pipe driven into the ground.

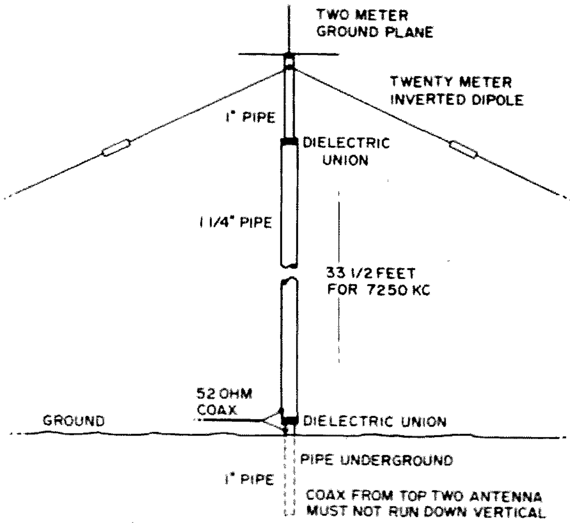


Fig. 1. Assembly of the antenna.

Each of the dielectric unions are one and one quarter on one end and one inch on the other. The one inch pipe driven into the ground can be any length to give a good ground and plenty of support. Here it is about eight feet long and is next to a good well. The ground is always moist, which helped in driving in the pipe.

The vertical must be cut longer than a normal vertical. Maybe because of the end effect caused by the pipe on top. Mine is thirty three and one half feet tall and is resonant at 7250 kHz.

Review and test of the Caringella ACP-1 Compressor-Preamp

John J. Schultz, W2EEY/1
40 Rossie Street
Mystic, Connecticut 06355

The ACP-1 is available in either kit or assembled form from Caringella Electronics, P.O. Box 327, Upland, California 91786.

The Caringella unit offers some unique features as an audio compressor. It is available at reasonable price in both kit and wired models.

One hears and has read about so many audio compressors, both commercial units and those described in various magazines, that the tendency is not to get particularly excited when another unit of this type appears on the scene. This was my initial reaction when I started to review the Caringella ACP-1 unit. However, upon some study of the compressor circuit and particularly after I had built and tested the unit, I felt that it had various unique features that made it well worth a detailed review.

Fig. 1 shows the schematic of the ACP-1 unit and the table below gives the "dry" specifications on the unit. I use the word "dry" to describe the specifications because they are technically accurate, but they give only a static presentation of the performance to be expected from the unit. A better illustration of the performance of which the unit is capable is shown in **Fig. 2**. This graph shows quite clearly the large compression range over which the unit is effective.

Circuit Description (Fig. 1)

Five transistors and one diode made up the semi-conductor compliment of the ACP-1 unit. The input stage, Q1, is a silicon N-channel FET (Texas Instruments 2N3819).

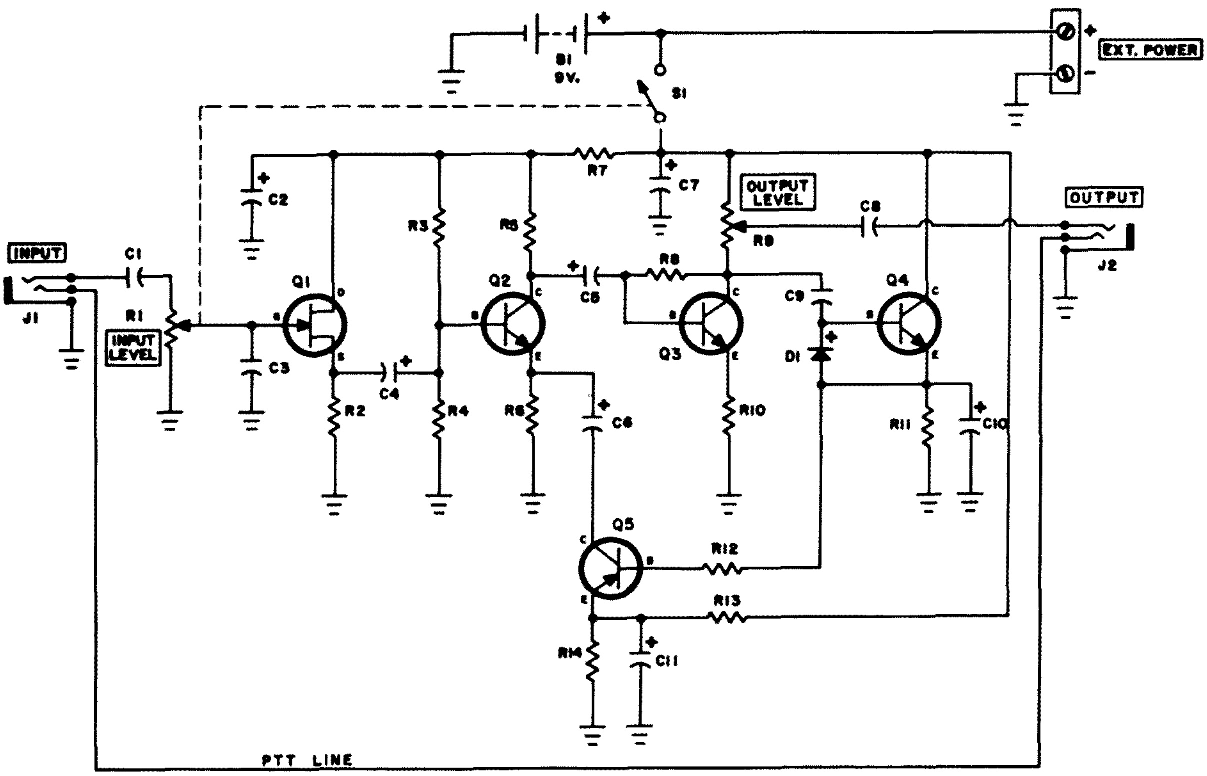

Fig. 1. Schematic and performance specifications for the ACP-1.

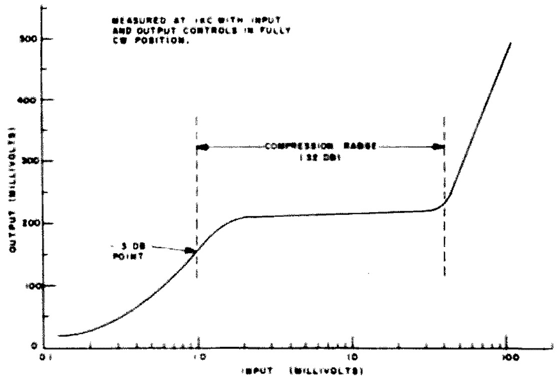

Fig. 2. Extreme compression range of the ACP-1 is illustrated by this graph.

This unit is an extremely low-noise device and, therefore, input noise from the "front-end" of the compressor is negligible. The 2N3819 also provides a very high input impedance for this first stage. R1, a 1 megohm potentiometer, serves as the input level control and is located on the front panel of the compressor.

Transistors Q2 and Q3 are NPN silicon devices used as common emitter amplifiers to boost the audio signal coupled through the source output of Q1. The emitter swamping resistor of Q2 is bypassed through C6 via Q5 in a circuit arrangement which provides the basic compressor action. The emitter swamping resistor of Q3 is not bypassed and the stage operates in a slightly degenerative mode.

The output signal is developed across R9, a 5K ohm potentiometer which also serves as an output level control mounted on the back panel of the ACP-1. Regardless of the setting of R9, however, part of the output signal is coupled through C9 to diode D1 and transistor Q4. D1 rectifies the audio signal segment coupled through C9 and the resultant dc current is amplified by Q4, another NPN silicon transistor.

The amplified dc output of Q4 is used to control Q5, a PNP germanium device. Q5 is operated in its linear resistance region and acts as a current-sensitive variable resistor. This variable resistance is in series with C6, the emitter bypass capacitor for Q2. The gain of Q2 changes as the resistance of Q5 changes since the effect of C6 is reduced and the stage operates in an increasingly degenerative mode.

Circuit Features

One of the significant differences over many other circuits that one notes in the foregoing description is the use of the 2N3819 FET input stage. The use of this FET provides two significant features. One is very high input impedance so that a correct match is provided to the usual hi-z crystal or dynamic microphone. Low impedance microphones require the use of a matching transformer for proper operation. The other significant feature is that the extreme low-noise characteristic of the FET prevents the noise buildup or noise "rush" that is common between speech pauses when using various other compressor circuits. The lack of noise "rush" is also partially due to the well chosen release time of about two seconds.

Another significant feature is the use of Q4 as a dc amplifier stage. The use of this extra stage provides a greater compression range than is possible when only a diode or dual-diode voltage multiplier is used to control the variable resistor element in a compressor. R11 and C10 determine the compression release time while the voltage divider formed by R13 and R14 set the output level at which compression action starts.

Construction

All the components supplied were of high quality and a complete set of plugs and battery connectors are included (the battery itself is not supplied). The components all mount, except for the panel controls, on a heavy duty glass epoxy printed circuit board. The enclosure has a gloss brown speckle finish with white lettering. Provisions are made for internal mounting of a 9 volt transistor-type battery.

The assembly, circuit and operating details are all described in a 3½ page folded sheet. Following the instructions given, the assembly time required was somewhat less than two hours.

Operating Experience

The unit was tried with a SB-34 transceiver and crystal microphone (as well as a SBE microphone through a matching transformer for the input). The SB-34 has no alc circuitry and particularly outstanding results were obtained. Stations worked consistently reported an apparent 6-8 db increase in signal strength when using the compressor. Audio reports were clean and no appreciable noisiness from use of the compressor was reported. It was interesting to note that the tubes used in a linear with the SB-34 started to redden slightly, a sure sign that greater average power was being generated. Transmitters having a usual 8-10 db range alc circuit should exhibit only a slightly less improvement when using the compressor.

SPECIFICATIONS

VOLTAGE GAIN: 40 db minimum

COMPRESSION RANGE: 30 db minimum

FREQUENCY RESPONSE: Flat 20 to 20,000 cps (without RFI filter)
Flat 20 to 5,000 cps (with RFI filter)

INPUT IMPEDANCE: 0.5 megohm

OUTPUT IMPEDANCE: 5K ohm

ATTACK TIME: 1 millisecond maximum (time required to reach full compresion from zero compression)

RELEASE TIME: Approximately 2 seconds (time required to reach zero compression from full compression)

SEMICONDUCTOR COMPLEMENT: 1 — n-channel silicon FET
3 — npn silicon transistors
1 — pnp germanium transistor
1 — germanium diode

FRONT PANEL: Input level control with on/off switch, 3-way phone jack for input connection

REAR PANEL Output level control, 3-way phone jack for output connection, terminal strip for external power connection

POWER REQUIREMENTS: 9 VDC to 12 VDC. 3 ma. to 5 ma.

DIMENSIONS: 4¼" wide x 2½" high x 3½" deep

MISC: Furnished with two matching phone plugs, high quality MIL-type glass-epoxy printed circuit board, and easy-to-follow instructions

SHIPPING WEIGHT: 15½ oz.

PRICE: Model ACP-1 KIT $18.50*
Model ACP-1 WIRED $26.50*
F.O.B. Upland, California
less battery

The unit was tried both using an internal battery and powered by the 12 volt line in the SB-34. In the latter mode, for best stability, it was found necessary to use a 100 pf bypass and a 100 ohm/50 μf decoupling network on the 12 volt line to the ACP-1. The need for these components may partially have been due to the use of an unshielded cable between the SB-34 and the ACP-1.

Summary

The ACP-1 confirmed its specifications as a superior compressor unit. The emphasis in the ACP-1 kit seems to be more on hardware rather than software but, in this case, the emphasis is certainly correctly placed.

The output level control is generally not necessary when the unit is used with a transmitter having a microphone gain control. This "surplus" control space on the back panel plus the space still available in the ACP-1 enclosure sorely tempts one to compact into the enclosure other small transistor or IC station accessories, such as tone generators, VOX or keyer units. I, in fact, easily put an IC keyer that was unhoused into the enclosure and there is still room for a VOX unit.

...W2EEY/1

Promoting vhf

An excellent way of promoting contacts, friendship, and interest in ham radio on the vhf bands is to collect a list of operators on a particular band and mode. In many areas the vhf bands are sparsely populated and for this reason there is much dependence upon ground wave contacts to keep the bands alive. Collecting the call, handle, and city of all known operators within a 200 to 300 mile radius and sending a copy to each new operator along with your qsl creates a feeling of comradeship which can't be gotten any other way. The new man appreciates being a part of the gang, knowing everyone's handle, and what to expect in the way of contacts.

Keep your list current by adding and deleting as soon as changes are made and making new copies at regular intervals. The list will be most useful if some blank lines are left for additions to be made between issues.

Usually there is someone in the area who has access to a copier or mimeograph, who can make copies at little or no cost. Postage costs the same as a qsl when the qsl is stapled inside the list and the two are sent together.

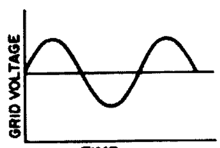
William P. Turner, WAØABI

ATV Video Modulator

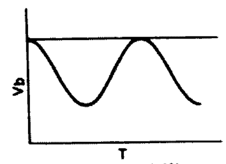
Tom O'Hara, W6ORG
10253 E. Nadine
Temple City, California 91780

Here is an easy way to put a 435 MHz transmitter on the air for ATV. This one-transistor video modulator will provide 10 MHz wide high resolution pictures when used with a good camera and a 450 MHz FM transmitter strip. Any of the FM transmitters that have a 5894, 6907, 6939, etc., dual tetrode, or home-brew rigs using 4 x 250's will work without sacrificing their FM audio capability. The AM or FM mode will depend only on which modulation jack is plugged in. AM phone can even be used by plugging in 1 volt p-p audio from a microphone and preamp.

The input accepts the standard 1 volt peak-to-peak positive going sync signal from the TV camera 75 ohm coax to a SO-239 UHF connector. A 100 ohm pot in parallel with the input impedance to the transistor amplifier approximates the required 75 ohm resistive termination. This is important as any SWR or roll off encountered as the modulating frequency increases will decrease the resolution. The transistor amplifier has a voltage gain of about 50, which is the maximum necessary for the largest tube–4 x 250. The 100 ohm video gain pot varies the negative swing as seen by the final grid. A .001 capacitor by-passes the 100 ohm emitter to give a boost to the higher frequency component of the video. The transistor has a ft of 25 MHz and a collector-emitter breakdown voltage of 300V yet costs only $1.21 each from Allied Radio or your RCA distributor. It's a 6AQ5 without filaments.

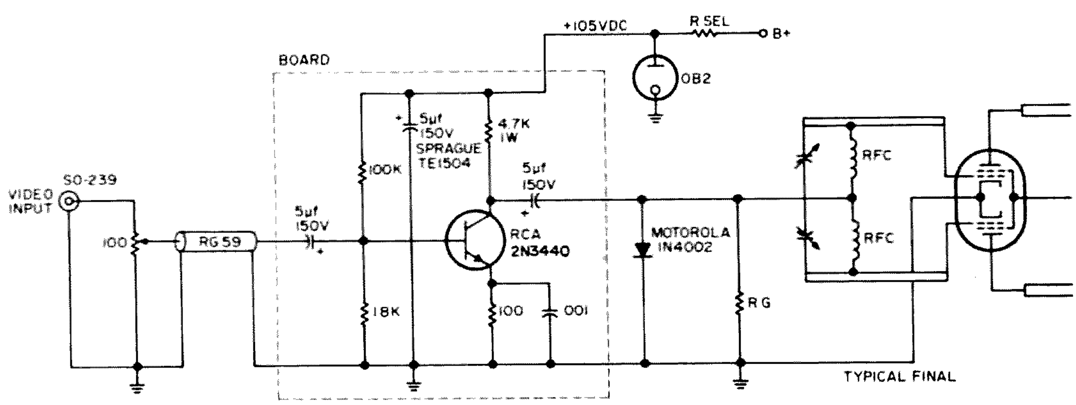


NORMAL AC ON THE BIAS VOLTAGE



DC RESTORED AC ON THE BIAS VOLTAGE

The output of the amplifier is coupled to the control grid of the final tube. The silicon diode dc restores the video so that maximum



Schematic for 435 mhz ATV transmitter.

power always occurs at the sync tips and gives a better contrast picture. This also lets you run the final at the highest class C continuous FM ratings.

Construction

The modulator must be mounted directly at the final grid to minimize *rf* pickup. The amplifier components should also have short leads. The components can be mounted on a copper, fiberglass, vector, or printed circuit board (PC board available from author—$3). The lead from the 5 µf coupling capacitor to the rfc should not be longer than ½". Take off any by-pass capacitor that may have been at this junction. Rg is existing grid bias resistor typically 10 to 22K. The B-plus dropping resistor is selected for a 20 ma flow from the lowest voltage source.

Operation

Plug in the vidicon camera,[1] flying spot scanner, or color bar generator and adjust the gain pot for best received video at a distant location. Your own set may give a false picture from overloading. Get a friend to pad down his UHF TV converter with 2 pf added across each variable tuning capacitor to look at your picture. He can describe your picture as you turn the gain pot, antenna and lens. The Blonder-Tongue BTD-44 converter makes a good 435 MHz ATV converter as all it takes is to screw the two variable capacitors all the way in and go into the TV set on channels 2 or 3 rather than 5 or 6. This will move reception up about 12 channels and 435 MHz will appear just below channel 14.

To keep sync buzz out of phone receivers and to keep modulation bars out of the pictures, I suggest choosing 435 MHz as the ATV carrier frequency. AM phone usually occupies 431 to 433 MHz and FM'ers 440 to 450 MHz. If you later add 4.5 MHz subcarrier audio[2] it will be still in the ATV frequency range at 439.5 MHz. FM transmitters such as the RCA CMU-15 get about 10 watts output and enable you to send a picture to most any station you can talk to on 2 meters with 5 watts. 144.45 and 146.1 MHz are usually used as the ATV calling frequency since recognizing an ATV signal is difficult unless the antennas are orientated right. The Cushcraft 16 element colinear seems to be the best antenna for ATV because of its reliable gain and bandwidth. Hope to SEE you on the air.

VHF, FET, More of

Not being a writer, I found this undertaking to be something short of impossible. But, being a ham fortunate enough to have two or three home spun circuits that work very well, I felt I had to share my joy with others.

The units described here are all based on the use of inexpensive plastic FET's. The designs are by no means mine but rather ideas collected from many sources. The principle source, and that which prompted my experimentation with FET's, was an article written by W6AJF, Frank Jones, in the Sept. issue of 73 for 1968.

My first endeavor was to construct a preamp for 436 MHZ ATV. Being primarily interested in signal gain, I constructed a two stage unit employing the Union Carbide UC734E epoxy field effect transistor. This unit consisted of a neutralized grounded source coupled to a grounded gate. I used sockets in this unit mainly because I am new at transistor construction and didn't want to damage them while soldering. Also, as Mr. Jones points out, this allows the selection of the best transistor for the first stage. I also shielded the drain from the source on both transistors and this proved to be very useful in preventing feedback.

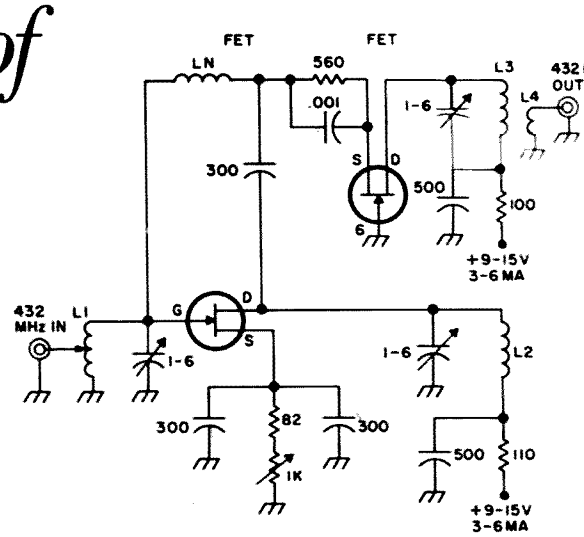

Fig. 1. 432 mhz FET preamp.

Parts List

LI - 1" long x ¼" wide copper strip. Center tapped.
L2 L3 - 1½" long x ¼" wide copper strip.
L4 - 1" #18 wire coupled to L3.
Ln - 2-4 turns #22 ¼-3/8 long x 3/16" diameter slug tuned.
FET - UC734 Union Carbide.

After the usual mistakes were corrected the preamp started to perform. Once the first stage was neutralized, which wasn't too difficult, I had a very hot preamp.

This was fed into an old uhf TV converter employing just a crystal mixer, but retuned to cover the 435 MHZ band. The results were excellent. Local signals, as well as one

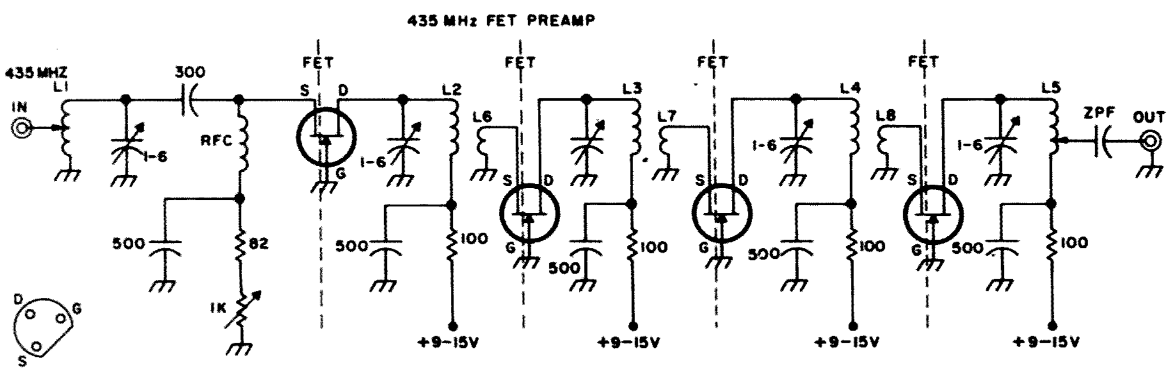

Fig. 2. 435 mhz FET preamp.

Parts List

LI - 1"x¼" copper strap - center tapped.
L2-L3-L4-L5 - 1½"x¼" copper strap.
L6-L7-L8 - 1" #18 wire parallel to cold end of output strap.
FET - Union Carbide UC734-E.

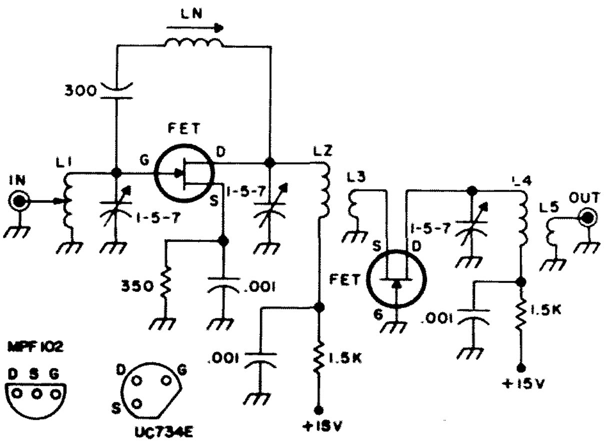

Fig. 3. 2 meter FET preamp.

Parts List

L1 - 4T #20 5/16" dia. x ½" L
L2-L4 - 5T #20 5/16" dia. x 7/8" L
L3-L5 - 2T pickup loop
Ln - 8 turns #26 ¼" slug form
FET - UC734E Union Carbide (1st choice) – mpf102 Motorola

about 100 miles distant, were received with S9 copy. Please note the only antenna at this time was a home brew 3 foot reflector with a dipole in the center.

After such astounding success with the two stage unit, I "naturally" concluded that four stages would be better.

I proceeded to build another preamp of that same configuration except for two additional stages of grounded gate. WOW, was that unit loaded with problems. I spent several weeks trying to tame it down but achieved little success. I then changed the input stage to a grounded gate and experienced the same problems. It became apparent that my shielding was inadequate so I put shielding on top of shielding until I had completely enclosed each tuned circuit. This cured the problem very well. I realize now that the circuit as I had originally built it would have worked very well if I had been much more careful in the way I had used the interstage shielding.

Both 436 MHZ circuits employed the UC734E FET mounted in sockets. Copper clad board was used for the base and also for the between stage partitions. Capacitors are all Arco # 400 miniature trimmers which are very inexpensive, but do a very good job.

It should be pointed out at this time, that all the accepted vhf techniques should be employed in this type of construction or success will be very limited. Shortest possible leads, good bypassing, and adequate shielding as shown above, are all essential at these high frequencies.

After getting both of these units working, I constructed a two meter preamp utilizing the MPF102 in a grounded source to grounded gate configuration. (This FET was used because I ran out of the UC734E.) This preamp required very little adjustment to get it working. It also seems to outperform my 417A preamp as far as noise figure vs gain. I say "seems" because I don't have the know-how or the necessary equipment at this time to perform noise figure tests.

As I have tried to indicate, I am no engineer and these units evolved out of a cut and try approach.

I heartily encourage any one needing a good preamp to try one of these because they are not at all difficult and require a minimum of parts. I suggest though, that before attempting to build one, the reader should refer to the very excellent article by Frank Jones in the Sept. 73 issue. His article covers the basics behind these preamps very thoroughly and takes care of what I have left out.

...K6KTP

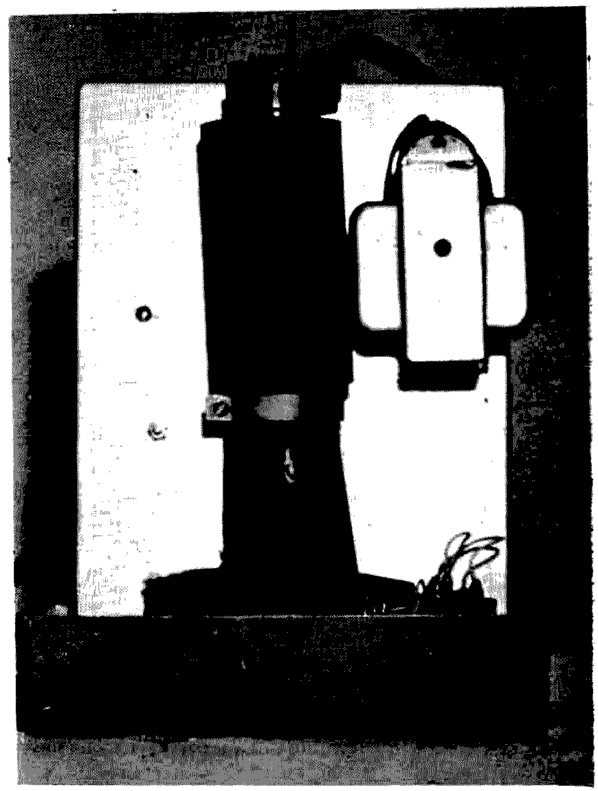
A Simple

Scope for RATT Monitoring

Sam Kelly, W6JTT
12811 Owen Street
Garden Grove, California 92641

Tuning in an RTTY signal is virtually impossible unless some form of tuning indicator is used. The most common indicators are the tuning eye tube, meter, and cathode ray tube. Of these, the most flexible by far is the cathode ray tube. In addition to providing tuning information it can be used to identify interference and check on proper transmitter operation.

For some reason, most amateurs shy away from building oscilloscope indicators. Actually, they are no more difficult than any other electronic project. This little indicator is about the ultimate in simplicity. This is due to the availability on the surplus market of the 902-A cathode ray tube. This tube is available for about $3.00. It has a deflection sensitivity of 90 V/inch making it

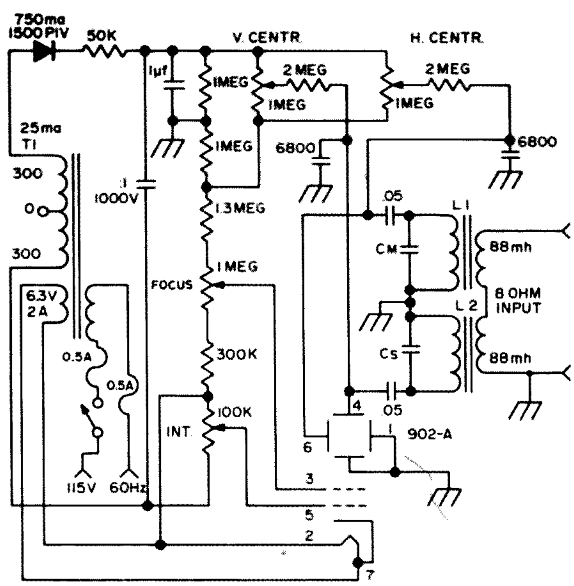


Top view showing water pipe shield installed. Note the small foam rubber cushion at the front of the tube.

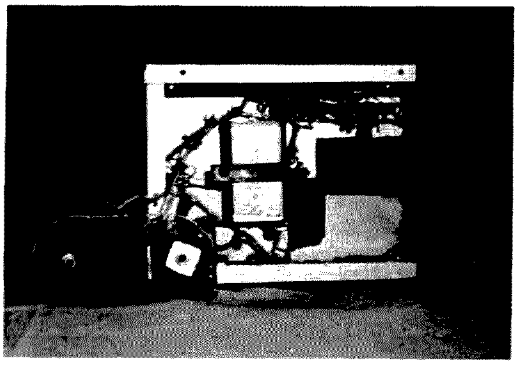
possible to obtain adequate deflection without amplifier stages. In addition, its high voltage requirements are modest, allowing the use of a small cheap power transformer (300-0-300 v) in a half wave rectifier configuration.

The scope was constructed on a 6 x 9 x 2 inch aluminum chassis. The circuit (Fig. 1) was divided into two sections. The power and oscilloscope control components were mounted on the panel and chassis. The input transformer – tuned filter networks were constructed on a 2 x 5 inch piece of vector board which was mounted underneath at the rear of the chassis on stand-offs. Leads to this board should be long enough to allow the board to be slid out of the chassis for tuning.

Due to the small size of the cabinet it was



Schematic for the Simple Scope.



Bottom view showing filter board removed for tuning.

necessary to mount the transformer with the core parallel to the axis of the cathode ray tube. This produced an un-wanted deflection. The cure was a tube shield made from a 4 inch length of 2 inch diameter galvanized water pipe. After cutting, the shield was de-burred and painted black.

All my receiver output lines have an 8 ohm impedance whether they are from the hf communications receivers, or the vhf FM system. A standard 88 mH toroid is used for a combination tone filter and step up transformer. To match the 8 ohm line a primary winding of 35 turns of No. 22 enameled wire is wound over the existing turns of the toroid.

After checking the wiring, turn the scope on, allowing it to warm up. Advance the brilliance control until a spot appears, then sharpen the spot with the focus control. Center the spot with the centering control. Connect an audio signal generator to the input. Remember, most audio oscillators have a 600 ohm output impedance, so a matching transformer should be used.

Now you are ready to tune the filters. There are several ways to do this. The results obtained by using a counter to check the frequency of your audio oscillator are well worth the trouble of obtaining the use of

this instrument. If you are active in Army MARS a counter can usually be obtained from your nearest test equipment pool.

The easiest way to tune the filter is to use a value of 0.033 uF for the space capacitor. With your oscillator set at 2975 Hz tune the circuit to resonance by removing turns from the toroid.

About 4 turns per Hz is a good rule of thumb. Next tune the mark filter using a 0.066 mF capacitor to start with, and the same procedure. The audio oscillator should be set to 2125 Hz.

An alternate method is to substitute capacitors until the desired frequency is reached. This is simpler than removing turns only if you have a large selection of capacitors.

Remember in both cases, a good grade of mylar or paper capacitor should be used.

If you can't get your hands on a audio oscillator, the output from a friends AFSK oscillator can be used.

In operation the input line is bridged across the 8 ohm input to the TU. The receiver BFO is turned on and the desired RTTY signal tuned in until a distinct cross is obtained on the CRT. The audio gain is adjusted to obtain the desired height.

Curtain Rods, Coat Hangers, and Control Links

Glen E. Zook, K9STH
818 Brentwood Lane
Richardson, Texas 75080

One of the recent trends in amateur radio is the rapidly increasing number of six and two meter FM repeaters. Since FCC requirements specify the use of a control link above 220 MHz, and since the 450 MHz commercial band "splitting" has rendered many older units obsolete, many repeaters utilize the 420-450 MHz band for the control link and for satellite transmitters and receiver links. Prime consideration must be paid to the antenna system used in these links. The master control link must use directional antennas, and directional, gain antennas are desirable for satellite links.

Although many of the repeaters are backed by large amateur groups with excellent financial position, others are maintained by small clubs or individual groups on a limited budget. These small groups must rely on donations of time and material to establish and maintain the repeaters. Since there are few 450 MHz antennas gathering dust in amateur shacks which could be donated to the repeater, these groups often make do with cut-down 2 meter ground-planes and similar antennas. The purpose of this article is to describe a yagi antenna which is very inexpensive (cheap!) and easy to construct, which will fulfill the antenna needs of these repeater links.

The basic items needed are described in the title: Curtain rods, coat hangers, a piece of threaded rod, and a piece of aluminum tubing. The boom is constructed from a cafe type of curtain rod. These rods come in varying sizes. Since there are two sections to each rod (one sliding inside of the other) two antennas may be made from each rod. The rods which extend to 48" and are brass plated make excellent booms for 420 – 450 MHz. All parasitic elements are constructed from coat hanger wire and the driven element is constructed from a combination of 1/4" threaded rod stock and 3/8" aluminum tubing. The parasitic elements are soldered directly to the boom and the driven element attached by a single No. 10 bolt. The antenna may be easily mounted either vertically or horizontally and weighs less than two pounds.

The first step is determining the spacing between elements and the length of the elements themselves. This may be done with the use of the various antenna handbooks. The antenna described in **Fig. 1** will work well at the high end of the band where most links operate. If desired the spacing and number of elements may be varied to result in more gain, better front-to-back ratio, etc. if desired. The dimensions in **Fig. 1** were chosen to facilitate the boom material available while giving good gain without critical adjustment.

Lengths of coat hanger wire should be cut to the desired length (three coat hangers will provide enough material for the antenna in **Fig. 1**). Next scrape the paint from about ½" either side of the center of each element.

The driven element should be constructed from a piece of 3/8" aluminum 2" longer than the calculated length of a ½ wave driven element. The extra is to allow 1" to be flattened and turned up at each end which will be drilled to hold the remainder

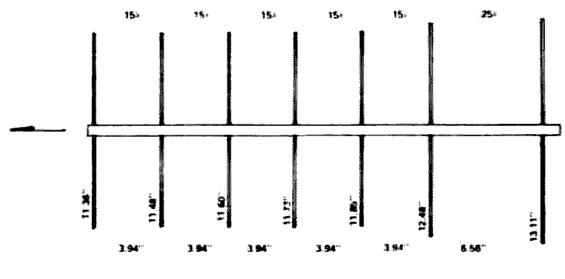

Fig. 1. Dimensions of antenna. 10.5 db measured over ground plane at Denton, Texas, Repeater Link.

of the driven element. The remainder of the driven element is made from two sections of ¼" threaded rod the length of which total the length of a ½ wave driven element. When these rods are mounted as in **Fig. 2** the amount of rod taken in attaching a nut to hold it to the remainder of the driven element will allow a gap in the center of the antenna. To this place the 300 ohm (don't worry about matching, I'll cover this later) twin-lead will be attached.

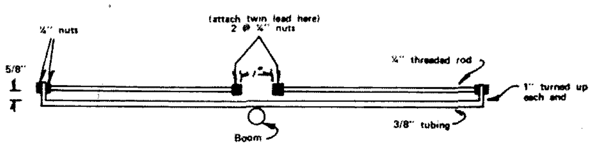

Fig. 2. Driven element.

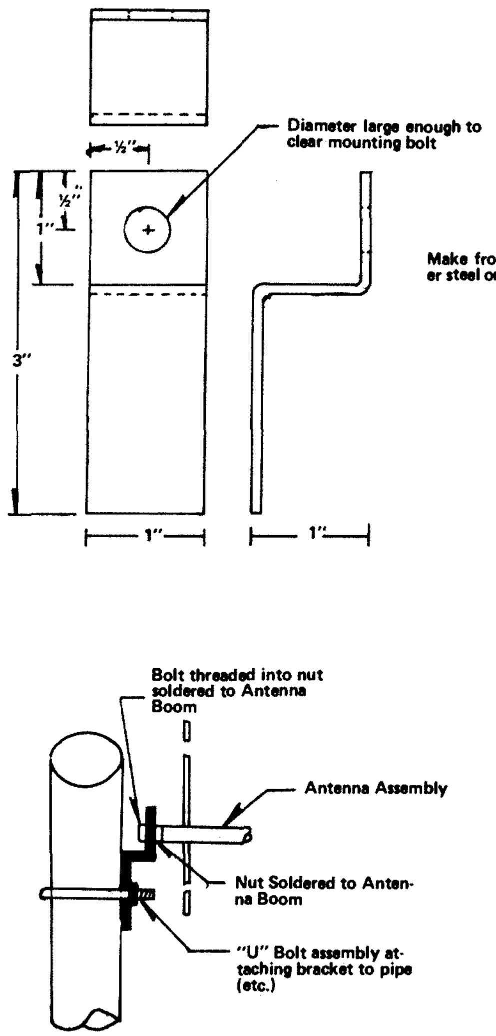
For most of the remaining steps a soldering iron or gun with a fairly high wattage rating will be needed for best results. The antennas in the accompanying photographs were built with an old 250 watt gun. No problems were encountered while soldering.

A close look at the curtain rod will show that it is basically a brass plated sheet of steel rolled into a cylinder. Since there is no weld at the seam the rod can be distorted by twisting. To overcome this the seam should be spot soldered every four or five inches. Most rods have a coating of laquer which should be scraped away at each spot. The whole operation takes about five minutes for the first boom, and less time after you get the "hang of it."

The next step is to attach a nut to the open end of the boom (as in photograph) by soldering. A 5/16" nut and bolt work quite well for most booms. The purpose of this nut is to hold the bolt which in turn mounts the antenna. If care is taken in soldering, the joint is quite strong and will support considerable weight.

Next the parasitic elements should be soldered on the boom 180° from the seam. Again make sure that the proposed joint is scraped clean. The elements may be aligned by letting one end rest on the bench as they are being soldered. Since the wire is relatively soft the remaining distortion may be easily eliminated.

The driven element is attached by a bolt inserted in a hole drilled through the boom and the driven element. The feed line is attached to the driven element as shown in the photographs. Finally the antenna may be mounted by inserting the bolt through a drilled hole into the nut soldered on the reflector end. Or, as an alternate the antenna may be attached to a small bracket (as in Fig. 3) and the bracket attached by "U" bolts or other means.



• Fig. 3. Bracket details, and assembly sketch.

The reasoning behind the use of a folded dipole driven element and 300 ohm feed line may be obscure to some new comers to the UHF bands. The reasoning is simple: 300 ohm twin lead is cheaper than, and has much less loss than most coax (and all coax within the budget of most amateurs). Also, it is easily available and fairly easy to work with. The main restrictions is to avoid sharp bends and to keep it spaced from other objects. This may be accomplished by standoff insulators which are easily obtained.

All obsolete commercial UHF equipment commonly available utilize a coax feed system. To match the 300 ohm feed line to the transmitter and receiver a balun must be built. This may be constructed from either a ½ wave length of coax or a 1½ wave length

of coax. If the dimensions in Fig. 4 are followed, do not use foam type of coax. If it is desired to use foam coax then the length must be modified to allow for the increased

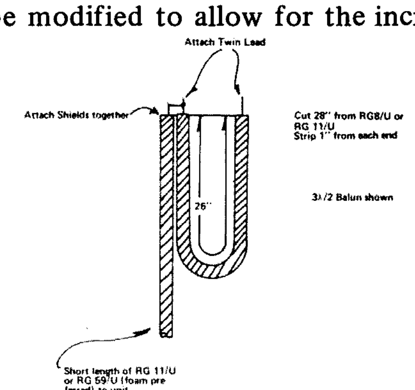


Fig. 4. Balun dimensions. Formulae (length of shield) in inches. V = velocity factor (.66 for regular coax):

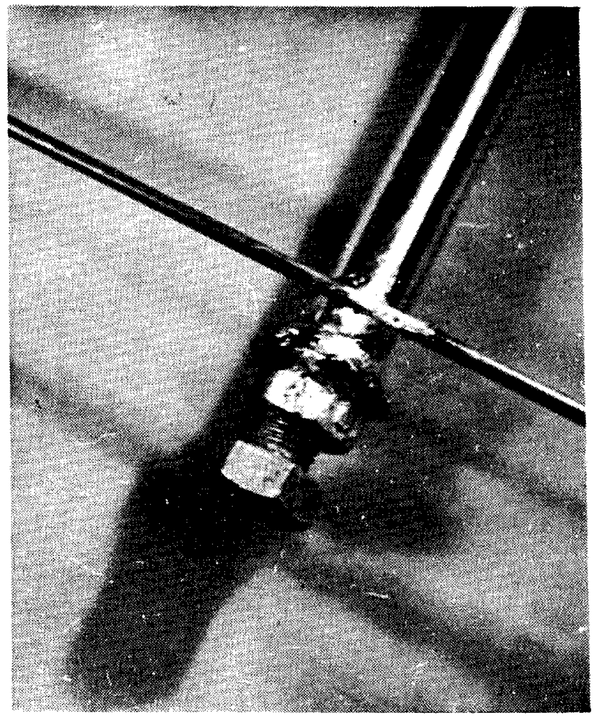
$$\lambda/2 \text{ Balun} = \frac{11811}{\text{FMH}_z} \times V \times .5$$

$$3\lambda/2 \text{ Balun} = \frac{11811}{\text{FMH}_z} \times V \times 1.5$$



Mounting nut details.

velocity factor. The formula for calculating the length is also part of Fig. 4.

Optimum gain in the antennas may be obtained by adjusting the spacing and element lengths as in any other type of yagi. However, formula derived lengths and spacing are usually satisfactory. Also, once the spacing has been determined for the first antenna, each additional antenna may be built with the same dimensions.

The prime advantages in using this antenna are the low cost (approximately 25 cents each) and the ease in mass producing several for use at remote receiving and transmitting sites. In the case of two or more remote locations it may be desirable to utilize a non directional antenna at the central site and directional antennas (as described herein) at the remote sites. In the latter case, the over all system gain will not be as great as when using directional antennas for both halves of each link, but the improvement over ground-planes at each end is remarkable.

One last note: After completion of the antenna it is desirable to coat the entire antenna with clear Krylon to prevent corrosion, especially at points which have been scraped clean to facilitate soldering. By the way, this antenna does not have to be used only on control links. It will do a fine job when used for other amateur work.

An Antenna With a New Twist

After reading the article on the Spiralray antenna[1] I decided to make one. I now work 2 meters AM and FM, so I thought this would be a good antenna to try, since AM is normally horizontal polarization and FM is vertical. While I usually use a 3 element vertical colinear for the FM because of its all directional gain, a beam is sometimes very useful.

Like most hams, I look around for the easiest and cheapest way for my first try at something. I just happened to have a Cush-Craft 11 element beam on hand which hadn't been put up yet, so I decided this should do the job. Although the Fig. 1 and the photo are for the 11 element beam, it will work with any beam on hand.

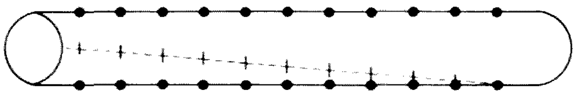

Fig. 1. Marking the boom for the new placement of elements.

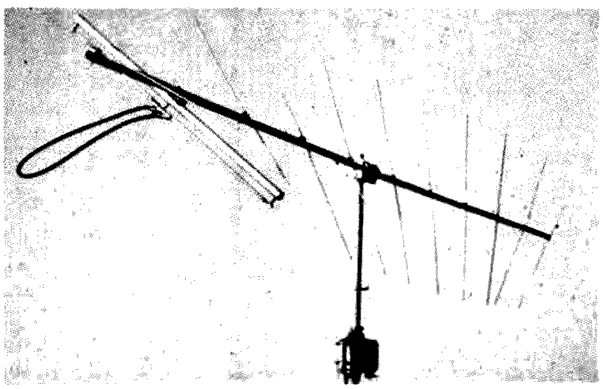
The first thing to do is to number all the elements so they will go back in the right place. Then remove everything from the boom. To get the proper twist in the elements take a piece of string and put one end



An antenna with a new twist.

through the existing mounting hole for the reflector and fasten it tight. Then run the string the length of the boom and tape it so that the end is ½ way between the existing mounting holes for the forward director. With a center punch make a mark for the new mounting holes along the string line and even with the old ones. The new holes could be made with a hand drill but I would recommend using a drill press so that they will be straight.

All that remains is to re-install the elements, check the swr, and put it up. Reports show excellent results on both AM and FM, with either vertical or horizontal polarization.

Facsimile and the Radio Amateur Part II

Ralph Steinberg, K6GKX
110 Argonne Avenue
Long Beach, California 90803

The response to my article on facsimile equipment[1] was most surprising and encouraging, with letters arriving from all parts of the United States seeking more information about the equipment and operations.

In the first article, mention was made about Western Union Telegraph Company donating some of its older models of the Interfax equipment to radio amateurs. Judging from the letters received, some of the amateurs did acquire some of the machines and are looking for information about schematics and facsimile paper for the Interfax equipment.

Through the courtesy of the Western Union Telegraph Company, schematics will be furnished, at no cost, by writing Western Union Telegraph Company, 60 Hudson Street, New York City, attention of Catalog and Specifications Library. Be sure to mention the model numbers of the Interfax equipment for which you need schematics. Also, this company will sell the facsimile paper for the machines at $1.56 a roll. This paper can only be purchased from the offices of the technical managers of Western Union. These offices are in the large cities of the United States such as New York City, Los Angeles, Chicago, Washington, etc. If you wish the address of the technical manager in your area, contact the manager of the Western Union office in your town and he will give you the needed information.

The most common question in the letters received was "Where can I secure facsimile equipment if I don't belong to MARS?" The answer to this is to check the advertisers in 73 as several advertisements appeared in the December issue offering facsimile equipment at very reasonable prices. Watch the ads each month as more of this equipment is gradually reaching the surplus market. Another source where this equipment can sometimes be purchased is at the retail surplus stores at military bases. The most likely place to find this surplus item would be in these stores at Naval Shipyards, Naval Air Stations, Air Force and Marine Air Stations.

Another question which was asked, "What frequencies are weather maps transmitted on?" There are a number of radio weather stations in both Canada and the United States. For frequencies, check with your local weather bureau and also write the U.S. Weather Bureau, Suitland, Maryland, which is headquarters of all U.S. weather stations. You will find more of these weather stations after you have become accustomed to the tones of facsimile on the radio bands.

In one letter the question was "Are there clubs or groups that are interested in facsimile and is there a magazine or manual published on the equipment?" On the first part of this query, I have not heard of any groups or clubs experimenting with facsimile, but would like to find out if there are any so the information could be passed on to others. A list could then be published of these groups or clubs so that information on facsimile could be exchanged. In reference to the second part there are no special magazines or manuals published for the radio amateur about facsimile equipment and operations. There possibly may have been articles published in the amateur radio magazines in past years, but I believe this article and those previous[2,3] on facsimile are the only ones of recent date. If there is enough interest in facsimile, allowing for the letters I have received, a series of articles could be prepared for later publication. Write *73* and let them know if you want more information published on this subject.

With slow-scan television legal on the low bands, facsimile may be the next mode of communications to follow in the near future. All it needs at the present time is enough interest by the radio amateurs to show the Federal Communications Commission, by petition, that facsimile will contribute to the state-of-the-art. It has been proven by Paul Blum, W2KCR, in 1957 and myself in 1968 that facsimile operations by the radio amateur could be a great morale booster for our servicemen in all parts of the world. With these operations being on record there is no doubt that other radio amateurs will continue to carry on projects to expand the interest in facsimile.

I wish to thank the many radio amateurs

Getting Your Extra Class License

Part V - Transmission Lines

Staff

Last month we examined some of the basic principles upon which antennas and radio-wave propagation operate, and promised to continue the discussion in this issue.

This time we'll to into an area which has been the subject of possibly more discussion—and fewer hard facts— than any other in all radio, amateur or otherwise. What we'll come out with won't be new—but we may offer you some new light on it along the way.

The questions from the FCC Extra Class study list which we'll be covering are:

22. Can a lossy transmission line be used to transmit signals? Explain.

32. Explain the properties of a quarter-wave section of radio-frequency transmission line.

44. What are the current and voltage characteristics along a transmission line when it is matched, and when it is mismatched?

55. A 70-ohm transmission line is connected to a 35-ohm antenna. Calculate the standing wave ratio (SWR), the reflection coefficient, and the percent reflected power. If 10 amperes are flowing in the antenna terminals, what is the current in a transmission line node?

79. Describe briefly some well-known types of antennas and antenna systems used by amateurs which do, and do not, reduce harmonic radiation.

As usual in this series, we'll rephrase these five questions into new ones which will hopefully include all the subject matter of these five together with enough additional related material to provide complete coverage of the subject.

Four of the five questions deal with transmission lines; only one deals directly with antennas. A logical first question for us, then, is "What Is A Transmission Line?" From this foundation, we can then ask "What Are The Major Characteristics of a Transmission Line?" We will find that one of the major, although secondary, characteristics is our old friend SWR; this leads to our third question, "What Is a Standing Wave Ratio?"

By this time we should have waded through more information than most of us ever want to know about transmission lines and their properties, so we can return to antennas. The major properties of antennas were covered last month, but with the main emphasis being placed upon their directional effects. Let's turn now to their frequency-sensitive sides and ask "How Are Operating Frequency and Antenna Design Related?" With that taken care of, we'll close our examination of antennas and transmission lines by determining "What Are The Most Popular Types of Antennas in Ham Use?"

All set? Let's get going.

What is a Transmission Line? Strictly speaking, of course, a transmission line might be considered as a "line that transmits." However, when engineers use the term they mean any line which is conducting electrical energy, and when we as amateurs (or the FCC examiners) use it we usually mean an *rf* transmission line, which is a special type of cable conducting *rf* energy.

Two general types of transmission line are in wide use; they are parallel line, of which the familiar TV twinlead and the open-wire feedline are common examples, and coaxial cable. While coax is probably in wider use because of a number of practical advantages it has over the parallel type, it's much easier to see the theory of what happens in the parallel variety so we will be talking primarily about parallel lines.

Before we do, though, we might as well summarize the advantages of coax; the reasons why they are advantages will come out as we proceed. In a coaxial line, the *rf* is

essentially confined to the interior of the cable and thus cannot radiate so easily. Neither can noise contaminate received signals. Coax is relatively insensitive to its surroundings as well. These three points are the major advantages; counteracting them are the facts that coax is (1) more expensive and (2) has higher losses, in general, than parallel lines.

Having disposed of coax cables for now, let's turn our attention to parallel lines to determine what a transmission line amounts to.

Any line conducting alternating current, at any frequency, loses at least some of that energy by radiation. The radiation is a direct consequence of the flow of alternating currents in the line, which create (or at least are accompanied by) reversing magnetic fields about the line.

A flow of current, though, requires two conductors, and if the two conductors are located very close to each other the radiated energy from one is effectively cancelled by that from the other. The net result is that almost no radiation occurs.

If the conductors are separated an appreciable fraction of a wavelength, however, this mutual cancellation cannot occur. Whenever the size of the circuit is physically such that no mutual cancellation is effective, energy will be radiated.

The terminated or "travelling-wave" antennas we examined last month were examples of "transmission lines," which had only one-way net current flow (ground serves as the second conductor in this example). Such a "transmission line" is an excellent radiator of *rf* energy—if it's big enough.

Mere physical size is not enough, either. The dimensions must be large in comparison to a wavelength. A cross-country power distribution highline fails to do much radiation of its 60-cycle power although it's many miles long, because its conductors are spaced only a minute fraction of a 60-cycle wavelength apart and their fields mutually cancel. A 6-meter antenna, on the other hand, radiates nicely from elements which are much shorter than the distance between highline conductors, and a microwave circuit can provide appreciable gain from a beer can!

Since a transmission line consists of two conductors, which are insulated from each other, then it must have some capacitance between them. In addition, each of the conductors also has some self-inductance, and of course at least a little resistance as well.

Let's look at a very short section of a very long line, such as that shown in **Fig. 1**. In even this very short distance along the line, the voltage between wires is not the same at all points, nor is the current in either wire.

For instance, the current flowing through the wires must by Ohm's Law result in at least some voltage drop across the resistance and inductive reactance of each tiny portion of each wire. That is, the voltage from A to D indicated by dotted line 1 is greater than that from B to C indicated by dotted line 2, because of the two voltage drops—one from A to B and the other from C to D— caused by the current flow.

Similarly, alternating current effectively "flows" through a capacitance, so that the current flowing from E to F is greater than that from F to G, because of the leakage current through the line's capacitance from F to H.

Since this is ac we're discussing, to be theoretically accurate we would have to resort to a set of differential equations—but for all ham purposes it's adequate to think in terms of Ohm's Law for ac. This tells us that the effect of the inductance and capacitance as illustrated in **Fig. 1** upon the voltage and current in the line must be an *impedance,* since only an impedance can relate voltage and current in an ac circuit.

And impedance, like a resistance, is essentially independent of voltage or current. It's determined by the physical characteristics of the device or component, not by the signal that happens to be applied or the devices to which it may be connected.

In the case of our transmission line, the impedance is determined by the inductance and capacitance of each tiny part of the line. Both the inductance and capacitance are distributed over the entire length of the line, rather than being lumped into coils or capacitors, and thus the impedance is an essential built-in part of the line.

Incidentally, this capacitance which helps form the impedance is no theoretical fiction. Should you ever be in need of small precision capacitors, you can cut them to measure from *rf* feedline such as TV twin-lead. All these lines are rated for capacitance in picofarads per inch; simply cut off as many inches as you need. It's a handy trick to keep in mind when

electrically small capacitors are necessary.

What Are The Major Characteristics of a Transmission Line? We've already met some of the characteristics of a transmission line. Its impedance is one of the most important, for *rf* use. But impedance is not the only characteristic—and a length of line lying on the floor has far different characteristics than does the same line when trimmed to dimension and installed in an *rf* circuit. Let's look both at the intrinsic characteristics of a feedline, such as impedance, capacitance, inductance, etc., and also at the effective characteristics or properties of specific lines of special length or with special terminations.

We have seen that the impedance of a line is determined by the inductance and capacitance distributed throughout the line's length. For *rf* transmission lines, the impedance is approximately equal to the square root of the ratio of inductance to capacitance. If the resistance of the wires in the line were absolutely zero, and the leakage resistance of the insulator separating the wires were infinite, then the line's impedance would be exactly equal to the square root of inductance divided by capacitance—and in *rf* lines the wire resistance is low enough and the leakage resistance great enough that we don't get into trouble.

However, the wire and leakage resistances *do* exist, so we can't ignore them completely. They contribute to losses in the line, and so provide a characteristic of the line which is called attenuation. Attenuation in any type of transmission line increases as the signal frequency goes up, because the wire resistance goes up and the leakage resistance goes down with increasing frequency. In most practical applications the attenuation of any line is given as a "decibels per 100 feet" figure; a line rated for 3 db/100 feet attenuation will lose half its power in every 100 feet of length. If you pump a kilowatt of *rf* into a 300-foot length of such a line, you'll get out only 125 watts. The first 100 feet of the line will lose half the input power or 500 watts, leaving only 500 to go on. The next 100 feet will lose half of that remaining 500, and the final 100 feet will dispose of half of the 250 watts which had survived the middle portion.

The attenuation of a line is at least as important as its impedance. The attenuation figures tell you how much power is going to make it through the line, and they also will affect the way in which the line looks to your transmitter—as we shall see shortly.

In Fig. 1, we assumed that the power going through our short section of transmission line was all going from a source to a load. That is, the line was carrying power only one way.

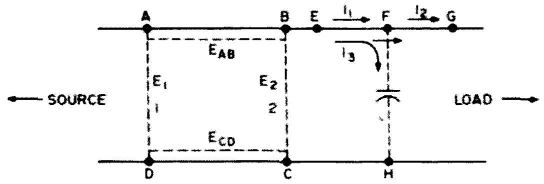

Fig. 1. The most basic physical characteristics of a transmission line are shown here. Assume that current is flowing from the source direction toward the load. The voltage from A to D must be the same as the sum of that from A to B, B to C, and C to D—but current flow through the wires means that the voltage drop from A to B and from C to D will be greater than zero, so the voltage between the two wires at A-D is greater than that at B-C. Similarly, current at point E includes that flowing to charge capacitance F-H, and so must be greater than that at point G. These voltage and current relationships define the impedance and attenuation of any transmission line.

In practice, this is seldom true. The nature of the fields and waves which make up *rf* energy (or any ac energy for that matter) being what it is, a one-way travel of any set of waves will stay one-way only so long as that set of waves stays in the same medium. When any boundary is reached—that is, when anything gets in the way—some of the energy is reflected at the boundary, and at least some of the reflected energy comes back in the direction exactly opposite to its original direction.

It happens to be possible, from a mathematical point of view, to account for *all* the reflected energy in terms of just two sets of waves. One set is considered to be the original set, going "forward" or in the original direction, and the other set is considered to be going in the exact opposite direction. This is known as the "reverse" or "reflected" wave, while the original set is called the "forward" or "incident" wave.

Note that this way of accounting for the energy does not claim that all the energy is actually contained in the forward and reverse waves; we actually do not know for sure exactly what does happen. It merely says that if we consider only the two sets of waves, we can account for what happens.

If we can account for what happens, and

our accounting method lets us predict what will happen in any normal set of circumstances, then it's a workable tool whether it's a correct one of not—and the concept of incident and reflected waves in a transmission line is just that, a workable tool. We don't need to know more than that in order to make use of it, any more than we need to know the atomic structure of steel in order to cut a hole through metal with a cold chisel.

Terman says the same thing in a different way on page 84 of his "Electronic and Radio Engineering" (fourth edition): "The voltage and current existing on a transmission line as given by equations 4-6 can be conveniently expressed as the sum of the voltages and currents of two waves." Notice that his sole reason for doing so was *convenience.*

Now that we've established the incident and reflected waves on a transmission line as convenient tools—without going any deeper into whether they actually exist as such—let's see how we must define each of them in order to make it into a useful tool.

The incident wave starts at the source and goes toward the load. It is the wave we considered in **Fig. 1**, in which both the voltage and current get smaller as we go farther from the source. Since the wave takes a definite time to go any given distance down the line, the instantaneous phase at any point along the line must lag as we get farther from the source. That is, the part of the wave most distant from the source must represent a part which left the source *before* any nearer part did.

There's nothing in the transmission line itself to alter the relationship between voltage and current in the incident wave, because the retarding effects of the distributed inductance along the line are cancelled by the advancing effects of the distributed capacitance and the net reactance is zero. Therefore the voltage and current at any point in the incident wave have the same phase relationship to each other that they had at the source.

All this means that we can describe the incident wave as a voltage accompanied by a current that is everywhere in phase with, and proportional to, the voltage. Because of the continual decrease of both voltage and current we saw in **Fig. 1**, both the voltage and current decrease as we go away from the source, and drop back uniformly in phase.

This description corresponds to that of a travelling wave, propagating away from a

source, and so we say that the incident wave travels *toward* the load.

The reflected wave, on the other hand, is identical with the incident wave except that it is travelling in the opposite direction. This means that it is largest at the load and gets smaller as it nears the source; its current goes toward the source rather than away from it, and its phase advances rather than dropping back.

The reflected wave comes into existence because of a reflection at the load end of the transmission line. Keeping in mind that the whole idea of incident and reflected waves is a *tool* based on a mathematical accounting for events, and not necessarily an accurate description of the events themselves, it's not too surprising to find that the generation of the reflected wave is dictated by equations in the mathematical accounting. Five separate sets of equations must be satisfied simultaneously to make the reflected wave account for events; we'll ignore the separate sets of equations and examine only their merged result:

The final result of the simultaneous solution determines a factor known as the "reflection coefficient", which boils down to be the ratio of voltage in the incident wave at the point of reflection to voltage in the reflected wave at the reflection point. If voltage in both is zero, as in the case of a short-circuit (which we shall examine before long) then the current ratio may be used instead—and since impedance is a quantity determined by voltage and current, it's possible to define reflection coefficent in terms of the ratio between impedance of the line and impedance of the load.

In a perfect line—one which has no losses and thus no attenuation—the reflection coefficient is the same anywhere on the line,

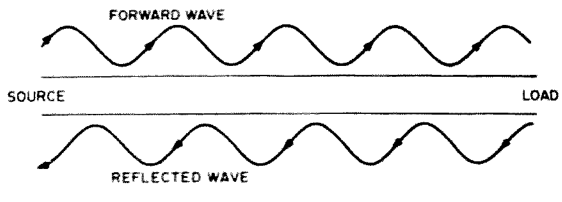

Fig. 2. Actual wave upon transmission line can be accounted for by two special waves called "forward" and "reflected" waves, each traveling in a single direction as shown here. Actual wave is then the net total of forward and reflected, at any point. Perfectly matched line has no reflected wave and forward wave is equal to actual wave; mismatch puts in "reflection" and modifies this situation. See text for details.

and is determined by that at the load. Any actual line, however, has attenuation; this attenuation acts oppositely upon forward and reflected waves because they go in opposite directions. Looking back at the source from the load, the forward wave gets larger as the source is approached because it has been affected less by attenuation, while the reflected wave gets smaller because attenuation is affecting it more. This means that on such a line, reflection coefficient is highest at the load or reflecting point, and becomes ever smaller as you move back toward the source. We'll see some practical implications of this fact, in the next section.

For now, though, let's back up a bit and look again at the relationship between the incident and reflected waves, and the actual voltage and current existing upon the line. It's actually very simple: the actual voltage at any point upon the line is the sum of the incident-wave voltage at that point and the reflected-wave voltage at the same point, and similarly the actual current at any point is the sum of incident and reflected currents at that point. If the two voltages (incident and reflected) are equal in value but opposite in sign, the "sum" would of course be zero since the two would cancel out.

Since the line is carrying ac, the voltage (at any one instant) is differenct at different points along the line both in value and in polarity. When we want to examine the situation all along the line rather than just at a single point, we speak instead of the voltage (or current) "distribution" on the line.

To see the part played by the incident and reflected waves in determining voltage (or current) distribution on a line, let's look at several examples of extreme cases. In all these examples we'll assume a perfect line with no losses just to simplify the situation. A little later we'll include the effects of losses upon similar examples.

For our first extreme, let's look at an open-circuited line which simply stops with no load of any sort connected to it.

With no place for any current to go, the current flow at the load end of this line must be zero.

But by our definition of incident and reflected waves, to account for this situation we must assume that both the incident and reflected waves do have current flow in them, of equal value but opposing sign. This is the only way in which the incident and reflected waves can cancel each other out to

produce an *actual* current of zero.

In other words, the open circuit reflects all the current which reaches it back down the line, reversing its polarity as it does so.

Our definition of reflection coefficient—the ratio of incident voltage or current to reflected voltage or current— tells us now that the reflection coefficient of an open circuit must be 1.0.

We can measure a voltage across this open circuit, which shows us that the voltage polarities at this reflection must remain unchanged although the current polarity reverses (had the voltage polarity as well been reversed, the measured voltage would have been zero).

At this point we have defined a reflection coefficient of 1.0 for an open-circuited transmission line. Let's move back along the line from the open circuit and see what happens to the actual voltage and current distributions.

At a point exactly ¼ wavelength from the open circuit, we are examining a part of the incident wave which is 90 degrees earlier in phase than that at the open circuit. The voltage of the reflected wave is 90 degrees *later* in phase than that at the open circuit, which means that from where we now stand the voltages of the incident and reflected waves are 180 degrees out of phase with each other. That's 90 degrees early for the incident combined with 90 degrees late for the reflected.

But in any ac waveform, any two points 180 degrees apart in phase have equal value and opposite sign. That means that, at this point, the voltages of the incident and reflected waves must always cancel each other out and the actual voltage at this point must always be zero.

How about current here? The reflection introduced a 180 degree phase shift in the current at the open circuit. The current of the incident wave is 90 degrees earlier than that, and that of the reflected wave 90 degrees later, so the currents of the incident and reflected waves are 90+180+90 or 360 degrees out of phase right here. But a 360 degree phase shift amounts to no shift at all in a periodic waveform—so at this point the current is maximum while the voltage is minimum.

Let's more another ¼ wavelength back so that we're examining a point a half wavelength back from the open. Now our voltage phase shift is 180+180 degrees, which amounts to no change at all, and we

CLUB SECRETARIES NOTE

Your club can round up some extra funds by imploring, cajoling, convincing, or forcing your members to subscribe to 73 Magazine. Never mind the cries of anguish, just remember that you are doing what is best for them—and the club.

Subscriptions to 73 are normally $6 per year. The special club rate is exactly the same: $6. The only difference is that the club treasury holds 25% of the loot and sends the rest to 73. Send us $4.50 for each one year subscription, in groups of at least five subs. Just think, if your club has 10,000 members you can quickly get $15,000 for the club on this deal!

Send the subscriptions to us on 3"x5" cards, giving the name, call, address, city, state and zip code of each subscriber. If the subscription is a renewal please include the address label from a recent 73 wrapper. Indicate all renewal subscriptions so we won't start a second sub. We have been known to do that.

Send to: Club Finagle, 73 Mag. PETERBOROUGH, N.H. 03458

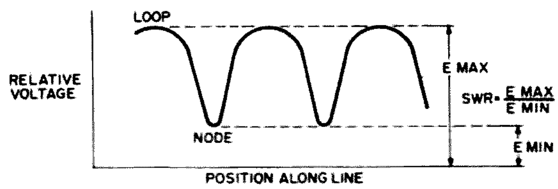

Fig. 3. Voltage distribution on transmission line having measurable standing wave ratio looks like this, if measured at various points along the line. Maximum-voltage points repeat every half-wavelength along line, as do minimum points. Ratio of maximum voltage to minimum voltage is one meaning of SWR; other meanings are equally valid as discussed in text. Note that voltage distribution does not follow a sine-wave pattern.

will find the same actual voltage as that which exists across the open circuit. The current phase shift is 180+180+180 or 540 degrees, which corresponds to a 180 degree change. The incident and reflected currents cancel each other out. Once again we find the same condition that existed at the open circuit.

As we move back on the line, at every ¼-wave interval we will find these conditions alternating. Every half-wave the conditions of the open circuit–full voltage with zero current–are duplicated, and at the intermediate ¼-wave points (usually called "odd quarter-wave" points) the opposite condition–zero voltage with maximum current–exists. It's brought about entirely by the phase relationship between incident and reflected waves, which is determined in part by the reflection coefficient at the open circuit and in part by the distance from our measuring point to the open.

Let's try another example. Instead of an open circuit, let's short the line out.

This gives us zero voltage across the short, together with maximum current. Curiously enough, that's the same condition we found at a distance of ¼ wave in from an open circuit.

To get the zero voltage, we must have again a reflection coefficient of 1.0 at the short, with 180 degrees phase shift for voltage and 0 degrees phase shift for currents at the reflecting point. That's the only way we can make the incident and reflected waves come out to match the measurable conditions at the short.

If we now move back a quarter wavelength on the line, we'll find a voltage phase difference between incident and reflected waves of 90+180+90 degrees, which amounts to no shift at all, and a current phase difference of 90+0+90 degrees, or 180 degrees, which produces cancellation. Full voltage and no current! The open-circuit condition, no less.

Regardless of our termination, we find that the terminating condition is repeated at half-wave intervals back from the load end of the line, and that its "opposite" occurs at the intervening ¼-wave points.

Let's look in a little more detail at that "opposite". When we terminated in an open circuit, which featured high impedance and almost no current flow, at the quarter-wave point we apparently had a short circuit, with low impedance and maximum current flow. When we terminated in a short, or low impedance, we found at the ¼-wave point an apparent open, or high impedance. We found, in effect, that a ¼-wave length of transmission line acts as a *transformer* to change high impedances to low, and vice versa.

Before we explore this idea any deeper, let's take one more example. What happens if we terminate a transmission line in another, identical, infinitely long transmission line?

Reflection coefficient, you'll remember, we defined as the ratio of incident to reflected voltage–and we added that it could be described in terms of the ratio of impedances also. If the two impedances are identical, the reflection coefficient must be zero. And if it is zero, then the reflected wave cannot exist; the actual voltage on the line and the incident wave must be equal to each other. In such a case, the line is said to be "matched." As it happens, we could substitute a resistor in place of any part of the infinitely long line, and if the impedance remained identical, nothing would change. This is the principle behind efforts to "match" antennas–and the success of our efforts to match impedances is measured in terms of a standing wave ratio or SWR.

We'll get into SWR in detail just a little later, after cleaning up a few loose ends about the major characteristics of a transmission line. We have determined that a line has capacitance, inductance, resistance, impedance, and attenuation, and that the energy in it at any point can be accounted for by incident and reflected waves travelling in opposite directions along the line. We have also determinded that any change of impedance along the line will cause a reflection, and that the amount of reflection is indicated by the reflection coefficient,

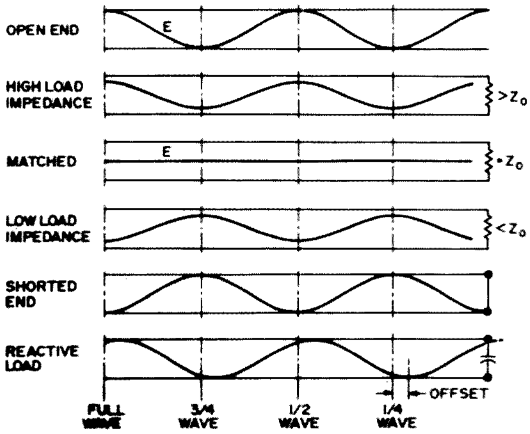

Fig. 4. SWR voltage patterns, similar to that shown in Fig. 3, for a number of different types of line terminations. Note range and phasing from open circuit (top) through matched condition (third from top) to short circuit (next to bottom). Effect of reactive loads is similar to open or short, with reflection coefficient of 1.0 for pure reactive loads; capacitance makes line appear longer and inductance shorter than physical length. Mixture of reactance and resistance changes phase (like reactance) and SWR (like lines 2 and 4) both.

which in turn is determined by the impedance ratio present at the reflection point.

We found that a reflection coefficient of 1.0 exists with either a short circuit or an open circuit as the load on the line, and that in either case the load condition repeated itself every half-wave back from the load, while the opposite condition occurred at the intermediate quarter-wave intervals.

But our examination of what happens when incident and reflected waves get together examined only a few extreme cases, and completely neglected the effects of line losses (attenuation). Let's see what happens when we plug the losses in too, and check out some in-between cases.

Remember that we found a complete cancellation between incident and reflected waves at the intermediate points, in our examples. This could not happen with any losses at all in the line, because the energy making up the reflected wave must always go farther along the line—out to the reflection point and back—than does the incident wave. The result is an almost, but not quite, complete cancellation instead—which leaves us a very small voltage or current in the incident direction, instead of zero. This is the only effect of small to moderate values of attenuation.

If we terminate a line in an impedance

greater than its own, but smaller than an open circuit—just to get a figure. let's say one three times as large as the line impedance—the result will be similar to that when we have an open, but not as extreme. The reflection coefficient in this case would be ½ instead of 1, which would make the reflected wave half as strong as the incident wave. When a cancellation would occur with an open circuit, only half of the incident wave would be cancelled in this case and the other half would remain. When a reinforcement would occur, the resulting sum would be a full-strength incident wave and a half-strength reflected wave, or 1-½ times the "matched" value. Both voltage and current would vary from half normal to 1-½ times normal, for a 3-to-1 variation.

At the quarter-wave point, the current would be 1-½ times normal and the voltage would be only half normal. This higher-current/lower-voltage condition defines an impedance LOWER than that of the line although the load impedance in this case is greater. We would expect this because we have already seen that a quarter-wave line transforms an open circuit into a short. The value of this lower impedance, though, bears the same ratio to the line impedance as the line impedance does to the load; in each case it's 3 to 1. That's necessary in order to keep the reflection coefficient constant all along the line. We can step up as well as down this way, and it's widely used.

What is a Standing Wave Ratio? We have just seen how any reflection upon a transmission line produces an interaction between the incident and reflected waves to create a pattern of high and low voltage points (loops and nodes) from that reflection back to the generator, and that this pattern does not vary with the instantaneous voltage or current of the outgoing energy.

Such a stationary pattern of voltage or current distribution is called a "standing wave" since it is not travelling. The amount of standing wave present on any line is measured by the "Standing Wave Ratio" or SWR, which is the ratio of maximum voltage to minimum voltage along the line, or alternatively the ratio of maximum to minimum current. This is very similar to the definition of reflection coefficient, and in fact SWR and reflection coefficient are related so closely that either can be converted to the other by a little arithmetic. The major difference is that reflection coefficient compares values in the forward wave with those in the reflected wave, while SWR compares actual maximum value on the line with actual minimum value and is thus somewhat easier to measure directly. Reflection coefficient, however, is easier to measure indirectly, and most of our "SWR meters" actually measure reflection coefficient instead, making the conversion to SWR by their scale calibration.

Some authorities speak of the "voltage SWR" or VSWR when they mean the ratio we have just defined, and use the bare term SWR to mean "power SWR". Power SWR is the square of voltage SWR, since the power in any resistor is proportional to the square of the voltage (or the current) applied to that resistor.

Fig. 3 shows a waveform view of what we've been talking about for so long, now that we have most of the words. While the illustration is based upon voltage waveforms, the same sort of thing is true of current waveforms as we saw a while back. Fig. 4 compares voltage and current waveforms in the SWR patterns created by several types of loads on the same type of line.

We saw last month that the presence of a standing wave upon an antenna structure made it easier for radiation to occur, and that also holds true of transmission lines. A high SWR will increase the likelihood of radiation from the line—which is usually an unwanted situation, since radiation is one major source of line losses.

A high SWR will also increase both leakage and resistive losses within the line, since it will increase current at the high-current points along the line ("current losses") and will increase voltage at the high-voltage points as well. Higher current means more power loss in a given resistance ($P=I^2R$), and higher voltage also means more power loss.

Most operators who take pride in a "good" operation, for these reasons, strive to achieve the lowest possible SWR in their transmission lines.

As we have indicated, SWR can be measured by actually measuring either voltage or current all along the line and then determining the maximum-to-minimum ratio, or by measuring the reflection coefficient with a "reflectometer" or "directional coupler" and converting to SWR. It can also be calculated by a much simpler rule: If the load impedance is known, and is a pure resistance without reactance, then the VSWR is equal to the ratio of load

impedance to line impedance (or line impedance to load impedance, whichever yields the highest figure). Our 3-to-1 example a few paragraphs back shows this, and how it comes about.

The VSWR, incidentally, can never be better than 1-to-1, since this says that the load and line have identical impedances and under this condition the line is perfectly matched. An SWR figure less than 1.0 simply says that you have a pretty bad SWR and have calculated it the wrong way; divide 1 by the figure you have to get the real SWR.

The VSWR of an open or a short circuit is infinite—but you can never measure it to be such a high value, because of line losses. The more loss in the line, the more the reflected wave will be reduced. The more the reflected wave is reduced, the less effect it can have upon actual net voltage or current an any point, and the smaller effect will produce a lower SWR. A long, lossy line is one of the best dummy loads available, because it can present a near-perfect SWR at its input end even when the load end is open circuited. For the same reason, SWR measurements should be made as close to the load end of the line as possible to escape this "swamping-out" effect of line losses.

Let's take as an example to calculate most of the things about SWR which the FCC wants you to know the case of a 52-ohm line terminated in a 104-ohm resistive load. We know immediately that the VSWR is 104/52, or 2 to 1. We also know that if 10 amperes are flowing in the antenna terminals, either twice as much or half as much will be flowing at a point ¼ wave back from the load because the VSWR is 2 to 1. Since the antenna's impedance is higher than that of the line, the ¼-wave point will have an impedance lower because of the transformer action—and in a lower impedance, more current must flow. This tells us that twice as much current will be flowing, and also that the point ¼ wave back is a current loop. Therefore 20 amps will be flowing at the loops, and 10 amps at the nodes.

Had the load resistance been less than that of the line but with the same VSWR (which would have required a 26-ohm load), the current at the ¼-wave point would have been only half that at the load. This would mean, in turn, that the load represented the highest current point or loop, and the other loops would have been at the ½-wave intervals back along the line.

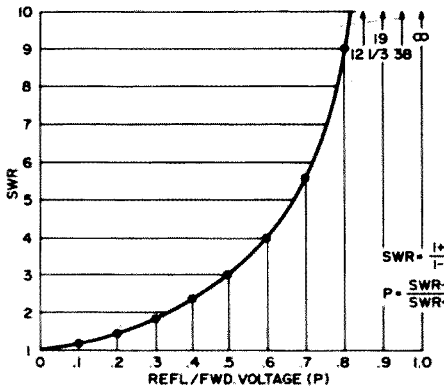

Fig. 5. Conversion from reflection coefficient to SWR and vice versa can be done by either this graph or the two equations shown here. Common SWR bridges and directional couplers measure reflection coefficient; any meter which is set to full scale with "forward" voltage or power and then read using "reverse" or "reflected" quantities probably works the same. Any meter movement can be calibrated for use with such devices by using horizontal scale here and taking SWR reading from vertical scale.

Getting the conversion from VSWR to reflection coefficient is fairly simple arithmetic. Fig. 5 shows the formula, together with a graph which permits reasonably close reading of the values (the formula is exact). With an SWR of 2, the formula tells us that reflection coefficient is (2-1) / (2+1), or 1/3. For every ampere or volt going up the line, 1/3 amp or volt comes back. But since actual energy is only that part of incident versus reflected which does not cancel out, it's quite possible to have 26-2/3 amps going up, 6-2/3 coming back, and find only 20 amps in the line! Either a forward power or a reflected power reading is meaningless alone so far as telling you what the actual power in the line may be; you must have both, and the actual power is the difference.

Just as VSWR is determined by voltage, and must be squared to get an SWR figure relating power, so is the reflection coefficient determined by voltage, and it too may be converted to a power figure by squaring it. This means that our VSWR of 2, produced by a 2-to-1 load-to-line impendance ratio, is a power SWR of 4, a reflection coefficient of 1/3, and represents a power reflection coefficient of 1/9. To get an actual power of 100 watts out, we must send 111.1 watts forward up the line because 11.1 watts (1/9 of 100) will be reflected back. Actually, it's a little more complex than that because the reflected power will be 1/9 of our forward power; this means that we must send more than 111.1 watts up. It works out to be 112.5 watts forward; 1/9 of this or 12.5 watts is reflected, and the remaining 100 watts is the actual power in the line. The percentage of reflected power is sometimes taken as the ratio reflected-to-forward times 100, and sometimes as reflected-to-total times 100. In the first case, the percentage of reflected power would be 11.1 percent (which is our original 1/9 figure); in the second it would be 12.5 (which is 1/8, and can be gotten by merely subtracting 1 from the denominator of our original figure). In practice, VSWR is met so much more often than is percentage of reflected power that you're not likely to have much trouble.

We've said that a high SWR was normally to be avoided. While this is true in transmission lines used to carry *rf* for considerable distances, there are exceptions. A quarter-wave section used as a transformer, for instance, must have upon it an SWR equivalent to the transformation ratio it is providing. If such a section is being used as a resonant circuit rather than as a transformer (that is, with one end open-circuited to produce the effect of a series-resonant circuit at the other end, or short-circuited to produce the effect of a parallel resonant circuit at the other) the SWR will be extremely high. While "infinite" is a bit too strong a term to apply to the SWR in such a case, it will be in the thousands or higher. VHF addicts who are familiar with the high currents to be found in coaxial or parallel-line tank circuits can attest to this fact.

In addition to the effects the SWR has upon line losses, the interaction between the forward and reflected waves modifies the line's input impedance. A 50-ohm line will only look like 50 ohms at the input end if it is matched to a 50–ohm load. If the load is 100 ohms instead, then the input impedance may be as low as 25 ohms resistive (for an odd number of quarter-waves of line length) or as high as 100 ohms resistive (for multiples of half-waves of line length).

But in between these extremes, even if the load itself is a pure resistance, the line won't look like pure resistance at all. Instead, it will show both reactance and resistance. Fig. 6 shows how the impedance varies along such a line with a VSWR of 2 to 1.

This fact helps explain why the pi-network transmitter output circuit, with its reputed ability to "match almost anything",

sometimes comes a cropper for no apparent reason. If the line length from transmitter to antenna just happens to fall in a region which emphasizes reactance, and with even a moderate SWR, the input impedance can become so reactive that no physical component in the pi-net can possibly provide proper adjustment. For instance, while loading is usually minimum with the output capacitor set for maximum capacitance, a pi-net in such an unhappy circumstance as we are examining here may already have far too little capacitance even when the capacitor is set at maximum. With critical line lengths and SWR as low as 2 to 1, it's possible to run into a need for *negative* capacitance (not inductance, which has opposite reactance sign but behaves differently with respect to frequency!). quency!).

It's also possible, at a critical line length on the other side of resistive point, to find that even with the loading capacitor set to minimum the circuit just won't load. This is because most of the capacitance of the circuit is being supplied by the line's input impedance.

In both cases two cures are available; one is to reduce the SWR, and this is the one usually recommended by most authorities. It's fine for a commercial, single-frequency operation, but hams must operate over the limits of a band rather than on a spot frequency and SWR necessarily changes from one end of a band to the other. The other cure is simpler—just adjust the line length by adding a 1/8-wavelength extension to the line. The SWR remains the same, but the length is no longer critical and the transmitter can once more be loaded. It will seem to act normally, for a change.

How Are Operating Frequency and Antenna Design Related? Any wire antenna is a circuit with "distributed" constants. That is, its inductance, capacitance, resistance, etc., are distributed throughout its length rather than being lumped into concentrated areas. Because of this, the current distribution in the antenna which results from applying a voltage at just one location depends upon, among other things, the length of the wire—which is measured in wavelengths. This is one of the most fundamental relations between operating frequency and antenna design, because operating frequency and wavelength are simply two ways of measuring the same property.

Last month we made the acquaintance of both "resonant" and non-resonant or "travelling wave" antennas. In both cases, the directional pattern of radiation was determined by the current distribution upon the antenna in conjunction with the relative phasing of the radiated fields from each tiny part of the antenna structure—and phasing also is related at least indirectly to operating frequency, because the frequency is a measure of the time between points of identical voltage in the signal, and phasing is a measure of the same quantity but in a different context. Frequency is measured in terms of the time to reach an identical voltage at the same point is space, while phasing is measured in terms of the time difference between points of identical voltage at different points in space.

Last month we concentrated largely upon the action of the non-resonant amtenna; this time let's turn our gaze to the resonant case.

A resonant wire corresponds to a transmission line that is an exact number of half wavelengths long and is open-circuited at both ends (a non-resonant antenna also corresponds to a transmission line but it is matched at both ends). We have already seen that such a transmission line will repeat the conditions at its end every half-wave along its length. If the wire is only a half-wave long, it will repeat the open-circuit of one end precisely at the open circuit which is the other end. If it is a full-wave long, again the open from one end will repeat at the other, but now both the opens will repeat at the midpoint of the wire as well.

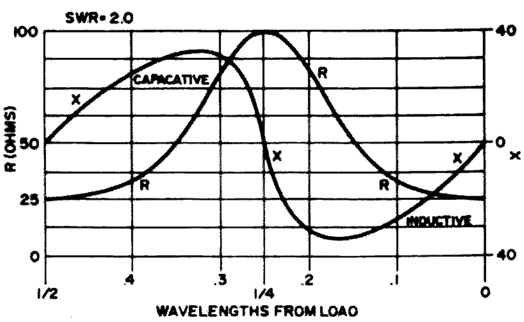

Fig. 6. Variations in both resistance and reactance along transmission line with SWR of 2.0 over any half-wave interval are shown here. Source of line is at left, and load is toward right. At 0 and ½ wavelength points, resistance is lowest and reactance is zero. At ¼ wavelength points, resistance is highest but reactance is also zero here. All other points have intermediate resistance, but also reactance. Patterns are similar for other values of SWR but variations are more extreme when SWR is higher. With extremely high SWR, resistance approaches infinite values.

A half-wave length of wire is two quarter-wave lengths back to back. But a quarter-wave length of transmission line open-circuited at one end will appear to be a short circuit at the other end. This would indicate that a half-wave length of wire open at each end should have an apparent short circuit at its midpoint—and except for the fact that the wire does have some "losses" (the radiated energy is lost so far as the standing wave upon the wire is concerned), it well might! The impedance is very low at the midpoint, at any rate. This low impedance provides a feedpoint for the antenna which matches a low-impedance feedline, and is known as a "current-fed" system.

The low-impedance points produced by quarter-wave transformation of the open circuits at the antenna ends will coincide only when the operating frequency is such as to make the antenna an exact half-wave long, electrically. If operating frequency departs even slightly from this one single spot, the two low-impedance points will not coincide, although the impedance at the center will still be low over an appreciable band of frequencies.

As we saw in Fig. 6, when even a moderate SWR exists upon a transmission line the impedance is pure resistance only at exact quarter-wave intervals along the line. At all other points reactance is present also. An antenna, being a pair of quarter-wave transformers, operates with a very high SWR upon its structure, and the variations shown in Fig. 6, are exaggerated still more in this case. This means that if operating frequency is not precisely that for which the antenna was cut, the antenna cannot be a pure resistance to its feedline. Again, reactance will remain low ever an appreciable spread of frequency. Bandwidth depends upon the particular antenna design; some have wider usable bands than others.

Outside this usable band of feedpoint impedances, the mismatch between antenna and feedline is so great that more power is reflected than is radiated. We say that the antenna in such a situation "refuses to load."*

For any single length of wire fed at its midpoint, there is a single lowest frequency

*(*Ed. note: A purist will quarrel with this terminology. An antenna does not "load." It presents a load to the transmitter. The transmitter will refuse to load into a mismatch. The antenna will refuse to radiate.)*

at which it can operate in this manner; that's the frequency at which the wire is electrically one half-wave long. If operation at twice this frequency is attempted, then each side of the antenna acts as a half-wave repeater rather than a quarter-wave transformer and it will refuse to load.

As we go up in frequency to three times the original value, though, we reach a point at which each half is three quarter-waves long, and the wire again acts as a pair of transformers. The loading conditions of the first frequency are essentially repeated here, and the antenna radiates nicely.

At four times the original frequency, we have repeaters again instead of transformers. In fact, at any even harmonic of the first or "design" frequency the halves will act as repeaters and a minimum of energy will be accepted. However, at any odd harmonic of the design frequency the halves will act as transformers and operation will be similar to that at the design frequency. The radiation pattern will, of course, be different at each frequency because of phasing interaction—but the antenna will accept and radiate the energy from the feedline.

The antenna we've been examining is, of course, the familiar half-wave dipole which appears in many variations such as the folded dipole, the inverted vee, etc. The same principles apply to all; at the design frequency and odd harmonics operation is excellent, and at even harmonics essentially no energy is accepted or radiated. Such an antenna is said to reject even-harmonics. If cut for operation at 7 MHz, it can also be used on 21 MHz.

Current feed is not the only possible way to feed an antenna. It could be fed at a high voltage point instead, with a transmission line of sufficiently high impedance. This would change things, since the high voltage point is at one end of the line. At the second harmonic, now, the line is a full wave long—and the antenna is still matched. At the third, the length is one and a half waves, and the matched condition persists. An end-fed half-wave, then, will accept all harmonics either—odd or even. Often called a "Zepp" antenna (such antennas were used on early Zeppelin airships), this type of antenna is popular with operators who like to use all bands and have only limited space in which to erect antennas.

Similar operation can be achieved with current feed by connecting several antennas in parallel and feeding them all at once from

the same line. Each antenna is cut for a different frequency. Those which are offering high impedances take little energy and so have little effect, while those which offer low impedance take most of the power and do most of the radiating. In such a case, the composite antenna will exhibit at least some SWR at all frequencies, because the "idling" antennas will put some reactance into the line, but operation is highly satisfactory. The major disadvantage—as for any all-band antenna—is that harmonics are radiated as well as is the fundamental frequency, if they should happen to reach the antenna in the first place.

Directive antennas achieve their effects by intricate phase relationships which we examined last time around. These are all frequency-sensitive, and most types of directive antennas are even more sensitive to operating frequency than is the simple dipole. The traveling-wave and reflective antennas are exceptions, since their effects are achieved differently.

In fact, the non-resonant traveling-wave antenna is almost independent of operating frequency, although its directional pattern changes slightly with changes in frequency. Such antennas, then, radiate harmonics as well as fundamentals, but can be used over frequency ranges as great as 2-to-1 or more without adjustment.

While our example so far has been the half-wave center-fed dipole, all that we have found applies equally well to a quarter-wave wire or whip mounted vertically upon a reflecting ground plane. The reflection from the ground plane acts as the missing half of the structure. Such antennas are used throughout the HF and VHF range, for both home and mobile stations.

What Are The Most Popular Types of Antennas in Ham Use? The number of different types of antennas is almost limitless, because virtually any structure which is capable of reflecting or refracting a radio wave and which can be coupled to a feedline of any sort *can* be used as an antenna. used as an antenna.

However, only a relatively few types have any major popularity. Preferences differ depending upon the frequency range of interest: the UHF addict for instance will almost never be found using a simple dipole, while the 40-meter enthusiast seldom sports a quad Yagi array.

The two major categories into which antennas can be divided when discussing popularity are "non-directive" and "directional". The major difference, in most cases, is that the directional antenna is usually set up so that it can be pointed in the desired direction, while the non-directive antenna is installed in a fixed location.

But at low frequencies, and in some other special cases, directional antennas may be permanently mounted in a single direction, and any "steering" that is to be done is accomplished by switching to another antenna rather than by moving the single structure.

Most hams operate primarily in the HF range from 3 to 30 MHz; those who use the three lower-frequency bands frequently stick to non-directive antennas, while those who operate primarily at 14 MHz and higher use some type of movable directional antenna.

VHF and UHF enthusiasts, almost without exception, perfer movable directional antennas. Occasionally they will use a non-directive antenna as a "backup" installation for local rag-chews.

The non-directive antenna classification includes three major types, each of which has many variations—each with its own name. The major types are the long-wire, the resonant horizontal, and the vertical.

The long wire, as its name implies, is a random length of wire. It is exceptionally popular among beginners because of its ease of installation. As experience with antennas is gained by the operator, the long wire is usually replaced by some other type which is easier to live with. A long wire's directive pattern is unpredictable, and it may or may not accept *rf* energy properly at any specific frequency. It offers little or no reduction of harmonic radiation—but the accompanying antenna tuner which frequently is necessary in order to get the antenna to accept *rf* energy does help reduce harmonics.

The most popular example of the resonant horizontal antenna is the half-wave dipole—which is possibly *the* most popular ham antenna. This antenna tends to reject all even harmonics of a signal, but will radiate odd harmonics almost as well as it will the frequency of its fundamental resonance.

A group of half-wave dipoles all connected together at the feedpoint, and each cut for a different ham band, is known as a fan antenna. Each dipole acts individually. The harmonic-rejection capability of the single dipole is lost, but such an antenna will operate on all ham bands and so is popular with many operators.

A single dipole may be loaded with

lumped-constant traps so that it automatically adjusts its effective length to fit several fundamental frequencies. Such an antenna is called a "trap" antenna and is in wide use as an "all-band" antenna for operation on the bands from 3.5 through 30 MHz. Its harmonic-rejection capability depends upon the exact design of the traps and upon the particular frequency in use.

A dipole antenna fed at the end rather than in the center is known as a "Zepp" antenna and is moderately popular. This type of antenna will radiate all harmonics of its fundamental frequency, in contrast to the center-fed dipole.

An offset-feed resonant horizontal antenna which has enjoyed moderate popularity from time to time is known as the "Windom" antenna. When cut to appropriate dimensions and fed from the proper off-center position, it provides a resonable match to 300-ohm twinlead on all the HF ham bands and so permits all-band operation. The trap antenna has displaced the Windom for many operators since it offers the same type of operation but permits use of coaxial feedline. Like any all-band antenna, the Windom has little harmonic reduction inherent in its design.

The most common vertical antenna in the HF range is the Marconi or quarter-wave vertical, which is simply a center-fed dipole cut in two at the feedpoint. The missing portion is supplied by ground reflections. Such an antenna is often used for 80 or 40 meter operation.

The corresponding design for 20-meter or higher-frequency operation is the ground-plane antenna, in which a metallic structure of rods replaces the actual ground to provide the reflections. This is a popular antenna up through the 50 MHz band.

Either the half-wave dipole or the Marconi may be "folded" to increase its feedpoint impedance. The dipole gets the name "folded dipole" while the Marconi becomes a "folded monopole" antenna. The "folding" consists of connecting another wire to the open end or ends of the antenna. In the dipole, the added wire connects the two open ends; in the monopole, the added wire connects to ground or the ground plane at the lower end.

Both the fan and trap variants of the dipole may be found in vertical versions as well, and both are moderately popular.

Among directive or "beam" antennas, far and away the most popular is the parasitic Yagi design. It comes in single-band, multi-band, and trap versions. The single-band corresponds in characteristics to the plain dipole, the multi-band to the fan dipole, and the trap to the trap dipole. Since Yagi has many more critical dimensions than does a simple dipole, it is inherently less apt to radiate harmonics. If a multi-band or trap version is in use, however, and a harmonic happens to fall within a region which is one of the antenna's higher-band operating regions (as, for example, a 10-meter harmonic of a 20-meter signal), it will be radiated.

Running the Yagi a close second in popularity is the "quad" antenna, which is a parasitic array of loops rather than rods. It is found in both single-band and multi-band designs; actually, a multi-band quad consists of several single-band quads sharing the same supporting structure and a common feedline, and so somewhat corresponds to the fan dipole.

VHF and UHF operators also make wide use of colinear arrays, most of which are variations of the Franklin colinear antenna and include both endfire and broadside array principles.

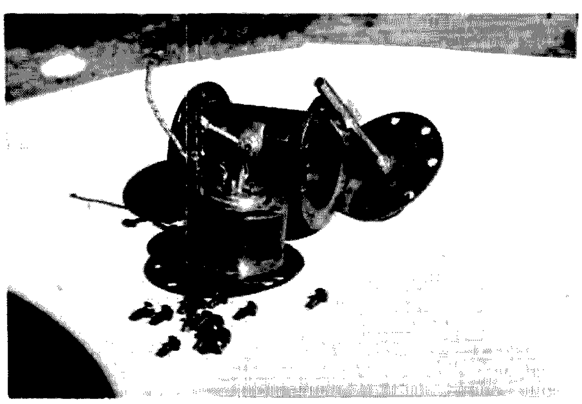
UHF operators, in particular, are employing parabolic-reflector "dish" designs for advanced work, as well as helical-beam antennas. These, however, are "popular" only in this limited area of interest.

We're a long way from exhausting the list, but it's long enough to more than accomplish the purpose of answering FCC questions. If you're really fired up with interest, check the various books we recommended last month—they'll keep you so busy studying antennas that you'll have time for very little else, and even then you won't be keeping up with the state of the art because it's changing too rapidly!

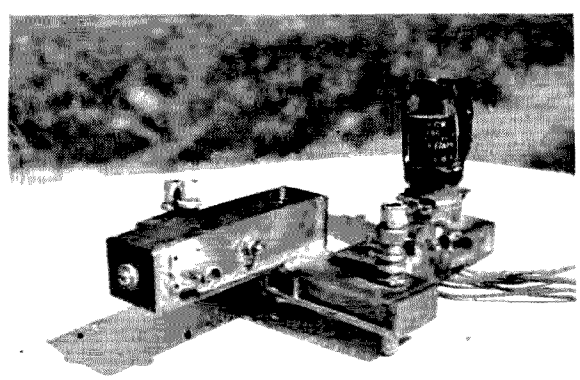
Soft Solder Construction of Cavities and Lines

Silas S. Smith, Jr., WA9VFG
2308 McCord
Murphysboro, Illinois 62966

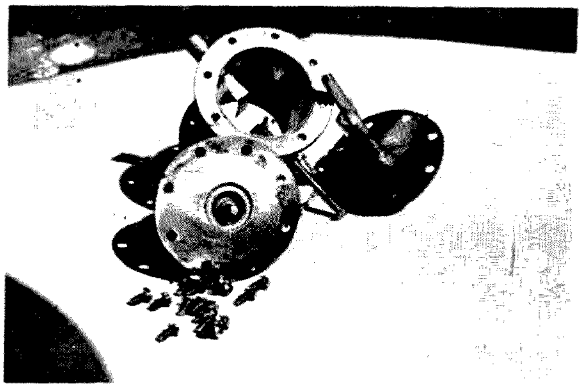
Most every piece of information on microwave equipment is either line drawings, or pictures showing very complex machined parts. It would be nice to have the proper skill and a machine shop. This isn't always practical however. Here then, is the next best construction method that any experimenter can use. Soft solder construction uses ordinary solder, either core or solid, and the only tools needed are simple hand tools found around any ham shack. So simple is the first method of construction described here, that line drawings can be followed almost exactly. I have repeatedly used this method. An oversized end plate, or what have you, is soldered to the line or cavity and then filed down to fit. Although a perfect fit is insured there are some disadvantages. A complex design cannot be built easily by this method, as any excess heat will cause all the parts to fall apart. The cathode cavity for the 416-B was constructed by this method. One secret for keeping things together is to start by soldering the larger and heavier pieces first, then progress to the smaller items. Along with this method, one of my favorite ways of construction uses ordinary copper or brass pipe with flanges made of large heavy washers. The large washer centers are laboriously filed out to the outside diameter of the pipe with a rat tailed file. Fortunately I found a friend to turn some out on a lathe. I used steel washers, but I would advise the use of brass if you can find a supply. After filing out the washers, the washers were then soldered to the pipe. Holes were then drilled and tapped. The ends are then draw filed to insure a good fit. The file is ordinarily used lengthwise but in draw filing, the file is held by each end. The file is then drawn over the material in a flat horizontal fashion. The ends could also be "lapped," using a good grade of emery cloth over a flat surface. The end plates were made of 1/16 inch stock. It's a good idea to mark the end plate and washer so they can be aligned, just in case the holes are not evenly spaced. The plate line for the 416-B uses this type of construction. This type of construction has several advantages: (1) material is cheap; (2) the line can be shortened easily; (3) easy access can be gained to the inner cavity; (4) can be used for any shape of line, round, square, etc. Lines or wave guides can be constructed of 1/16 inch or heavier flat stock by allowing enough extension to form a good solder bead. "C" clamps can be used to hold the sides in place. After soldering, the joints may be wiped. Wiping is a method whereby the solder is brought up to the melting point and wiped with a cloth. The purpose is to give a neat look and to remove the excess solder. If the solder is too cool the appearance will be rough. "Fanning" with the blaze of a torch until the solder is just about ready to flow will give a smooth surface. Oftentimes the cavity or line will become



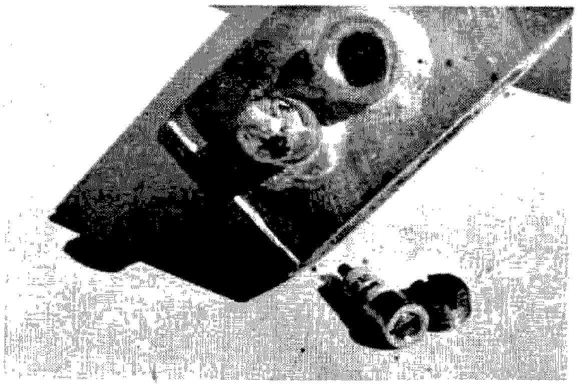
Soft solder construction.



Parametric amplifiers.



Using washers of steel or brass soldered to the pipe.



Crystal diode holder.

the support for other components. One component, the crystal diode, for instance, can be rather easily mounted. A suitable crystal diode holder can be constructed from a nut. The i.d. should clear the body of the crystal centered and soldered over a hole in the wall of the cavity or line. The hole is drilled to fit the main body of the diode crystal. A cap to hold the crystal in place is cut from a bolt with the same thread and size as the nut. The cap need only be approximately 3/16 inches long with a screwdriver slot cut at the top.

I usually use threaded BNC fittings. Soldering a threaded nut to the walls of a cavity or line presents a special problem. During the soldering process, the threads of the nut fill up with solder. The simple solution would be to use a 3/8 -32 tap to clean the nut, but trying to find a tap that size is a still bigger problem. In the meantime, I dirty up an old BNC or the threaded portion of an old pot, and use it to hold the nut in place and keep my fingers crossed that it doesn't get soldered. I suppose that I have about 50% luck. Tubes are often mounted within the cavities. The gold nugget, 416-B, is one such tube. Mechanically there are two problems in using this tube. One, the grid requires a threaded hole 3/4 inch 40 threads per inch and two, the cathode requires a mount. I had a machinist turn out some rings 1/8 inch thick with a 3/4 inch hole 40 threads per inch. I soldered these rings in place for the grid connection. As for the cathode mount, I used finger stock made from brass weather stripping. This is an excellent material for finger stock as it has lots of spring and is easy to cut and shape. One way of cutting the weather stripping is to sandwich it between two pieces of hard wood. Hold firmly in a vice or with "C" clamps. Use a hack saw to cut slowly, evenly spaced slots. The finger stock can then be shaped. Literally speaking, the next method is cooking in oil. This is a useful method used in soldering large parts where heat is not of consequence. This is the oil bath method. Oxidation becomes a big problem when parts are being heated and usually requires the use of flux. Flux does one of two things: one, it will etch away oxidation; or two, it will flow over the heated area and prevent oxidation. Larger parts require a lot of heat; thus, oxidation will occur, so an etching flux is necessary. In the oil-bath method, the parts to be soldered are assembled in a tray or shallow pan filled to a level sufficient to cover the area to be soldered with a high ignition point oil. The oil and parts are heated enough to cause the solder to flow freely. The oil acts as the flux in the fact that it keeps the air from the heated parts. Although the soldering is actually done in the oil, very good results are to be expected. A simple household detergent can be used to remove the oil and you will have very bright soldered parts. This method is also useful in salvaging parts from printed citcuit boards, or from "can" type structures in which parts are sometimes mounted. The XYL's cooking range can be used as a heat source. As a word of caution: safety precautions should be taken. It would not be unreasonable to use goggles and gloves. There is always a danger of reaching the ignition point, thus a fire. Keep a box of ordinary baking soda close at hand. In case of fire sprinkle the baking soda over the fire and avoid breathing the fumes. This is a trick the XYL has probably used many times when cooking. Here are a few ideas which I hope will dispel the notion that one cannot build cavities, lines, or wave guides without a machine shop.

...WA9VFG

Police Converter

W. G. Eslick, KØVQY
2607 E. 13th
Wichita, Kansas 67214

Besides having the fun of building this police converter and listening to the exciting calls, this circuit has other possibilities as shown in Fig. 2, as a 2-meter oscillator for your 2-meter converter (ugh on using a transistor oscillator into a diode harmonic generator as of old).

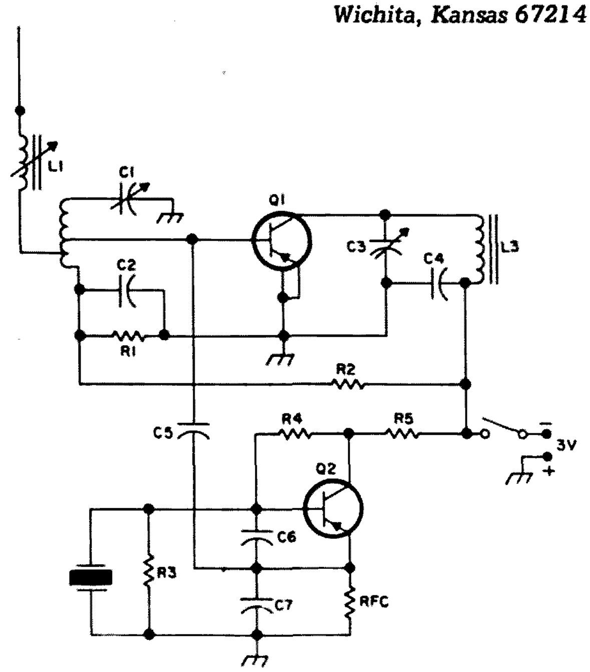
I also made up a one transistor oscillator using a 48.383 MHz. HC18/U third overtone xtal to see what kind of a signal it would put out on 2. On my bench, about 15 or 20 feet from my receiver, it put out almost as good a signal as my Millen grid dipper. There was also 48.383 signal present about ½ the strength of 145.15 MHz. I didn't try to trap it out. This will make a good signal source for 2M and with proper crystal, a cheap frequency standard for club or MARS frequency.

I also tried modulating it as a modulated oscillator (not on the air) it FM'd quite a bit, but could be read. I am sure that with a cheap final stage it would make a nice low-power transmitter for transmitter hunts on 2M, etc. A 2N1141 would work as a final here, but I can't say how much output you'd get.

A few of you may not of ever seen this oscillator circuit. It is Scotch for sure, using one transistor third overtone oscillator/tripler. What more do you want? I am sure there are others like me who lift part of a circuit from a magazine and use it.

I hope this will suggest many circuits to you. Another thought would be a small signal generator and a good hot check for third overtones (provided the output coil was tuned to the 1st, 2nd or 3rd frequency marked on the crystal. All overtone crystals (I think) are marked with overtone frequency. In other words, a 48 MHz crystal could put out 48 MHz (without a tuned circuit—if you wish), 96 MHz and 144 MHz. I haven't tried this oscillator to see if it will work higher harmonics of the crystal.

Getting back to the police converter; some commercial jobs use Japanese transistors and I used 10K in the base circuit of the mixer back to ground and I lost a 2N2996. I had to use a 2.2K. I mention this as a point to check carefully when you use different types of transistors.

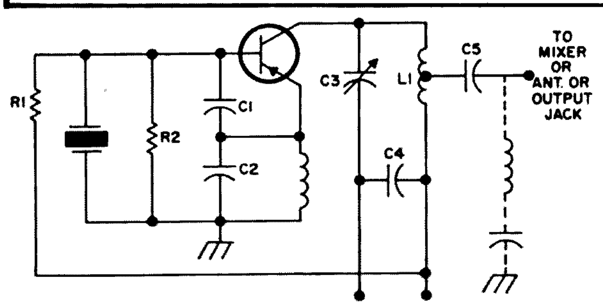


Parts List

C1 = 2-15 pf trimmer
C2 = .001 mfd.
C3 = 10-200 trimmer
C4 = .01 to .05 mfd (Iused .05)
C5 = 5 pf.
C6 and C7 = 33 pf.

L1 = 6T #24 on ¼" slug form
L2 = 4T #14 3/8" dia. ½" long tapped at cenfor base of Q1 and 3/4T from cold end for antenna.
RFC = aircore 17T #24 ¼" dia.
L3 + Loopstick ant. from junk transistor radio.
R1 = 2.2 k
R2 = 27 k
R3 = 10 k
R4 = 18 k
R5 = 15 to 27 ohms
Q1 = 2N2996 TI
Q2 = 2N1141 TI
xtal: see text.

The police frequency here is 155.15 (I understand this may be true over the USA, but I'm not sure—better check) and as in any superhet, the oscillator can be above or below the incoming signal. Crystal frequencies between 51.9 to 52.250 (being on the high side of the received signal) will permit the broadcast radio to tune to the converter and,



Parts List

R1 = 18 k
R2 = 10 k
CI = 27 pf
C2 = 27 pf
C3 = 1-12 pf trimmer
C4 = .01 mfd.
L1 = 3½T #14 3/8" dia. 5/16" long
L2 = 16T #24 aircore ¼" dia.

L3 and C6 can be a 48+ Mc. trap
Xtal = 48+ mc. (depends where you want on 2 M)
Q= 2N1141 TI

crystals between 51.183 to 51.533 (low side of signal) will also permit converter to work into a BC radio. Compute it thus:

155.15 MHz - .550 MHz (low end of BC band) = 154.6/3 = 51.533 MHz

155.15 MHz - 1.6 MHz (high end of BC band) = 153.55/3 = 51.183 MHz, which is the crystal frequency for each end of BC band.

155.15 MHz + .55 MHz = 155.7/3 = 51.9 MHz

155.15 MHz + 1.6 MHz = 156.76 3 = 52.25 MHz

Select any crystal frequency between these points, but be sure there isn't a local or a strong station picked up on your BC radio at this point or you will have a squeal or garbled output.

Three volts powers this nicely. If you use 9 volts, resistors will have to be changed and that means metering each transistor and checking oscillator output and checking the gain of the mixer.

This converter placed near (3 or 4 inches) or laid on a transistor radio so both loops are coupled somewhat is all that is needed.

A word to save some of you young 'uns some grief, if you get this idea! You select the proper crystal and this circuit to listen to a club frequency on two meters.

Happy listening to police or ham frequencies with this and may it furnish you with other project ideas to build. ...KØVQY

The Neglected Mini Vee Beam

Stan Johnson, WØLBV
855 So. Fillmore Street
Denver, Colorado 80209

Many of the current crop of hams do not have even a nodding acquaintance with the Vee beam – yet it is an antenna with some very positive advantages: it will provide excellent gain on three or more bands; is easy to build and tune up for real efficiency over a wide range of frequencies; and it is so neat and inconspicuous that it will be a lot more popular with the neighbors than the usual quad or tri-bander.

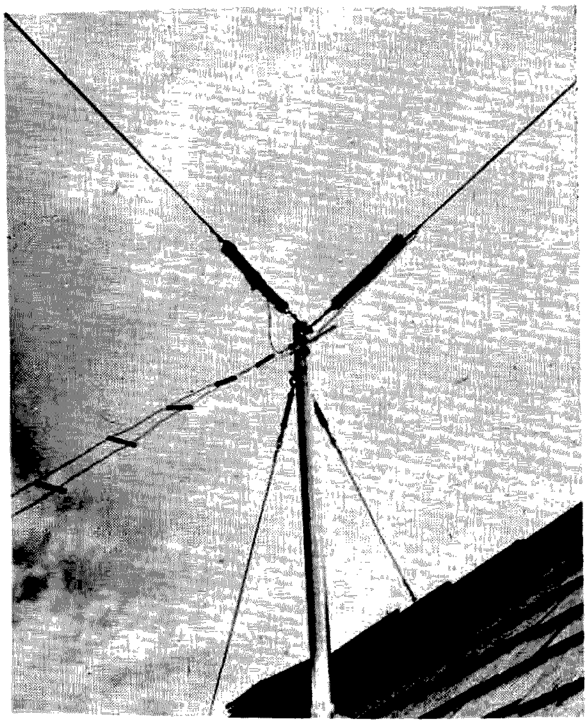
Probably one of the reasons that the Vee beam has been so neglected is that those hams who do know something about the configuration usually feel that the antenna is not practical unless you live in the country – or at least on an acre of ground.

Happily, this point of view is not quite true. Size does help, of course, but it is possible to build a Vee beam which provides very worthwhile gain on 20-15-10 meters, yet can be put up on the average city lot, particularly if you have an understanding neighbor who will allow you to run a small portion of it over one corner of his property.

And such an antenna does perform effectively. The one illustrated was first put on the air on 28 megacycles. In actual use, a flattering number of CQ's resulted in three and four station pile-ups on the frequency – from stations 1500 to 2500 miles away.

On 10 meters, of course, this is no great trick, ordinarily. But the transmitter used for test purposes was an ancient, modified Heathkit At-1, running about 40 watts input, *AM Phone*, and doubling in the final amplifier, which meant that there was something less than 20 watts in the antenna. Despite the low power, reports of "10 db over S-9" were commonplace, and one CQ was answered by a station in northern Japan.

The theoretical gain of a Vee beam of the dimensions shown is approximately 6 db on 10 meters, or about that of a typical 3 element beam. On 15 meters, gain is somewhat less, approximately 5 db, and the gain is in the neighborhood of 4 db on 20 meters. In the writer's opinion, though, and the opinion is shared by others, a long wire antenna of any type will deliver more in actual



Mini-Vee beam for 10, 15 & 20.

communication gain than a parasitic array which is rated at the same level.

This is *probably* true for at least two reasons. First, long wire antennas do not seem to require as much height, to deliver low angle radiation, as is needed for the smaller beams. Second, receiving "efficiency" – if there is such a thing – seems to be markedly better. At any rate, a Vee beam or other long wire type of antenna, will often dig out DX which other local stations are having difficulty receiving, and pull in that DX with less QSB. This could be accounted for by the fact that the long wires develop both vertical and horizontal polarization – and in addition, the larger capture area provides for a kind of diversity reception.

Perhaps *none* of these theories is entirely correct – but there is no question about the results; long wire antennas, particularly Vee beam and rhombics, have justly earned a reputation for generating outstanding signals.

A Practical Vee Beam

The drawing, Fig. 1, shows the layout of a Vee beam which is small enough to be practical for many hams. It is fed by a tuner, the circuit of which is shown in Fig. 2. Regular readers of "73" will recognize the tuner as being a modification of one described in a past issue by W5DWT. It is simpler than the W5DWT version because it is designed for only three bands. Despite its simplicity, the tuner will bring the antenna to exact resonance at any frequency in the three bands, and will provide a virtually perfect load for the transmitter, allowing standing wave ratios as low as 1.1 to 1, or beyond the accuracy of the usual swr meter.

The antenna is likewise very simple, consisting of two wires, mounted parallel with the ground, and as high as local conditions permit. The antenna shown in the photograph is approximately 25 feet above the ground, higher, of course, would be better.

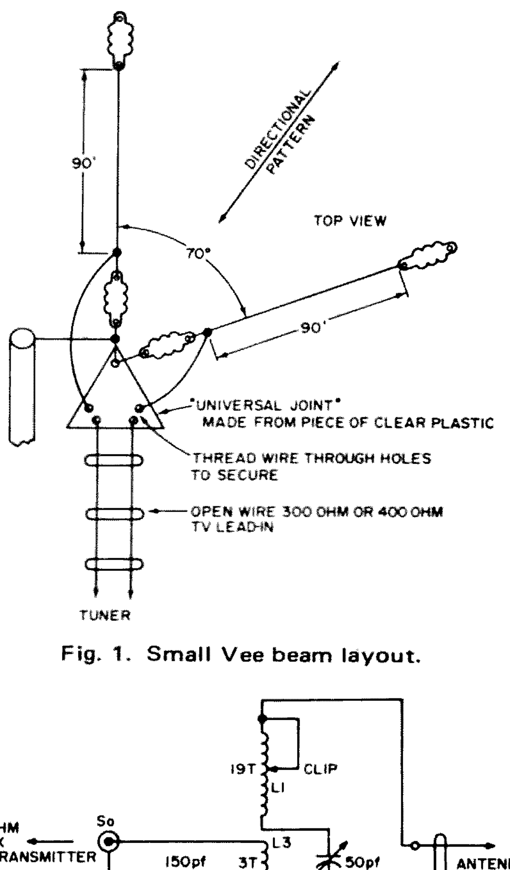


Fig. 1. Small Vee beam layout.

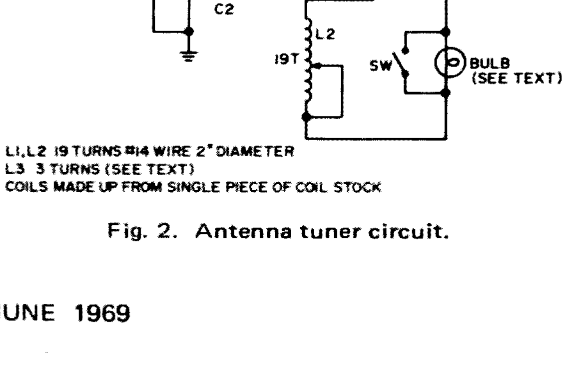

Fig. 2. Antenna tuner circuit.

Ideally, the feed line would drop down from the antenna at right angles, however in practical application this frequently is not possible. Both the photograph and **Fig. 1** show a kind of "universal joint" made up from a piece of clear plastic, which serves as the termination point for the feed line, and allows the feed line to leave the antenna at almost any convenient angle.

The feed line itself is the open wire "ladder" type of TV line, either 300 ohm or 450 ohm (preferably the latter). This line is adequate for any SSB rig which does not have a linear amplifier – or for a CW rig up to 200 or 300 watts. For powers above that, the line should be made up with number 14 wire, and either ceramic or clear spreaders.

Remember that even a 90 foot wire, loaded up with ice, can become pretty heavy, so if you live in W1 land be certain to use strong turnbuckles, screws, etc. The same thing applies for W4's, who on occasion experience what they call "atmospheric disturbances" that blow down palm trees.

The 70-degree angle is about optimum for an antenna to be used on three bands. However, if this angle isn't possible, you can narrow it to 50 degrees, or, preferably, use a larger angle, up to as much as 90 degrees. The last-named angle will reduce gain somewhat on 10 meters, but will give better results on 20 meters.

The Vee beam provides a "figure 8" bidirectional pattern. With the dimensions given, the pattern is quite broad.

Building the Tuner

The tuner for the Vee beam is made up on a 5 x 7 x 2 inch chassis. Building the tuner requires a minimum of parts: two tuning condensers, one length of coil stock, a switch, a dial light bulb, some insulators, and miscellaneous hardware.

The smaller of the two variable condensers, (50 pf.), should be double spaced. Since it is used at a low voltage point, even a midget variable like that shown is adequate for a fair amount of power. A single spaced variable condenser, 150 pf. or larger, likewise should do the job even for the more powerful SSB rigs run barefooted. If you go in for a gallon, use condensers with more spacing at both points.

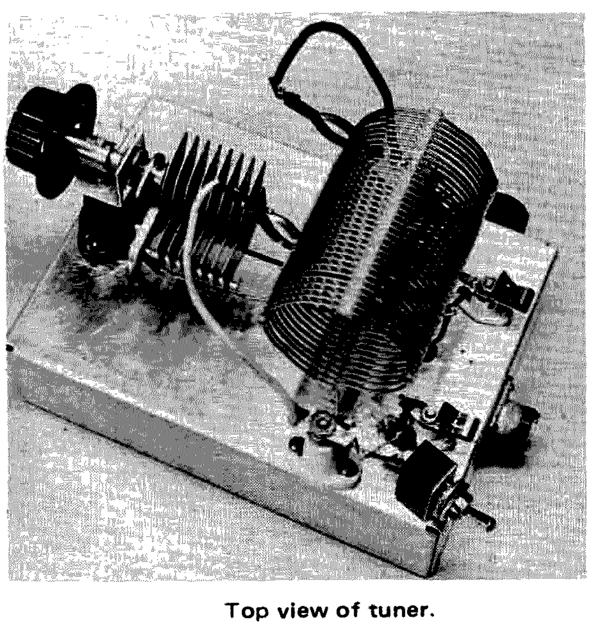
The coil can be of standard coil stock (B+W 3900). If you have difficulty in obtaining coil stock, you can roll your own, as detailed in the writer's book, "Ham Antenna Construction Projects," which is available from any Howard W. Sams' distributor.

Notice that the coil is actually *three* coils. This is accomplished by clipping the coil stock at the proper point with sidecutting pliers as shown in the photo. I found that clipping the coil is easy, but following the turns by eye to make certain which winding is which can be confusing. The best answer is to use an ohmmeter as a continuity meter – or a flashlight bulb and a battery. It sounds ridiculous, but the tuner illustrated failed to work properly, and it took me, a ham for over 30 years, all afternoon to discover that the connections to the clipped-apart-coil were wrong!

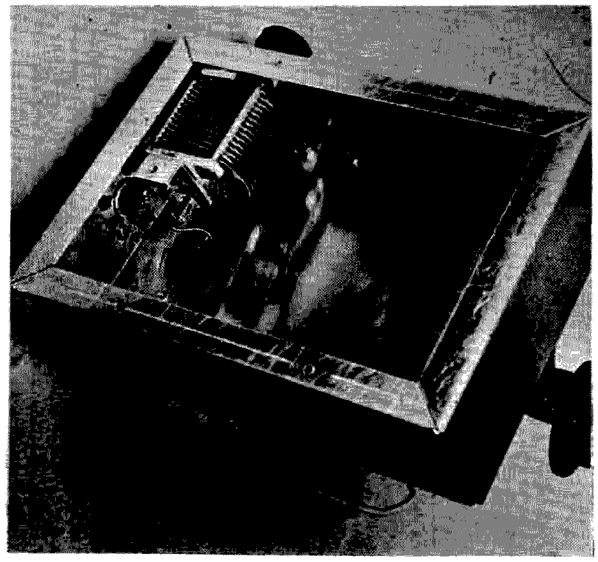
The tuner is so simple that the actual wiring is at most an hour's job – and if you are handy with a soldering iron, you can do it in half that time. Use some scrap lengths of No. 14 wire, if possible, for the leads. Note that the variable condenser above the chassis is mounted on an insulator so that both the rotor and stator are "above ground." The variable condenser below the chassis can be mounted directly to the chassis, since the rotor is grounded.

Tuning Up The Antenna

The Mini Vee beam, like any center fed antenna fed with a tuned line, can utilize a simple resonance indicator which shows when there is actually power in the antenna. And this is what counts – *not* the swr ratio. A low swr is a fine idea, especially with an antenna fed directly with co-ax, but contrary to what appears to be an unfortunate popular opinion, a low swr reading *may* mean simply that you have lucked into a critical length for the coax you are using. Low swr does *not* guarantee your antenna is working efficiently – a brutal fact explained in an earlier "73."



Top view of tuner.



Bottom view of the tuner.

With a tuner like that shown you have the best of both worlds: the tuner resonates the antenna and its feeder – *and* allows tuning out the reactance on the coax which runs between the tuner and the transmitter. An swr meter inserted in this line *will* show low swr, and furthermore the reading is honest!

The resonance indicator on the tuner is simply a dial light bulb in series with one feeder. (The system is balanced, so in theory, at least, the same current will appear on both wires of the feed line.)

A number 44 bulb will handle up to 35 watts or so – and if two bulbs are put in parallel, they will handle considerably more power. Higher power will require use of a Christmas tree light bulb, or, if *it* blows out, simply clipping a flashlight bulb over a portion of the feeder, as shown in Fig. 3.

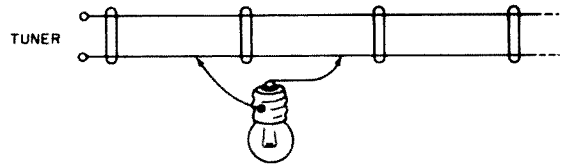


Fig. 3. Resonance indicator on feedline.

Step One

In tuning up any antenna system, I like to start out by tuning up the transmitter to a suitable dummy load. For example, with low power, a 40-watt oven bulb (the clear glass makes the filament easier to see than on a frosted bulb). As the first step it is always nice to know that the transmitter is putting out power.

Next, let's tune up on 28 MHz. Remove

the dummy load from the transmitter and hook up the coax to the tuner. Place the clips on the tuner coil in approximately the position shown in the photograph.

Set condenser C2 at approximately one-half capacity (assuming 150 pf).

Adjust the load controls on the transmitter so that meter readings indicate the antenna appears to be taking some power. Now rotate C1, and watch for the bulb to light. If it does not, throw the switch, and try again. If you still get no indication (chances are you will) move the clips either closer to the center, or further out. Try to have the same number of turns on both sides.

You may make a few false starts, but in a couple of minutes you should arrive at a point where tuning condenser C1 through resonance will cause the bulb to light. Now adjust C2 for maximum brightness of the indicator bulb, and "touch up" the tuning of the transmitter. The name of the game is to achieve maximum brightness on the indicator bulb without, of course, overloading the transmitter – which probably has a plate milliameter to indicate proper input.

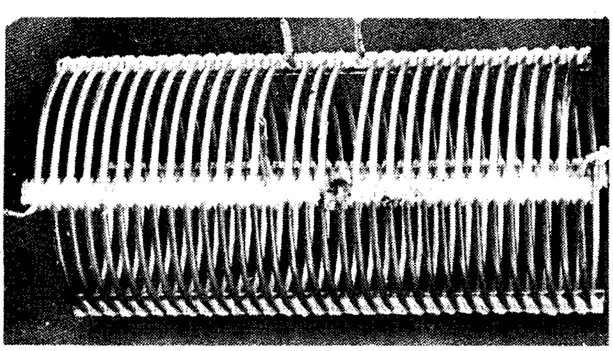
If you want to insert an swr meter into the coaxial line, now is the time to do it – and chances are very, very good that the swr will be quite low, although careful adjustment of C2 may bring it still lower.

Once you have discovered the proper tap points for 10 meters, indicate them with a dab of paint (or finger nail polish) alongside the clips so that it will be easy to return to the same spot.

Tune up on 15 meters and 20 meters follows exactly the same procedure. When you have maximum brilliance on the bulb you have the system in resonance and virtually a written guarantee that you will "get out."

Additional Bands?

Yes, the Mini Vee will tune up on the



Coil stock is clipped to form three coils.

other bands as well. It will tune up on 6 meters with the coil shown, and you may get it to tune up on 2 meters as well, although most of the coil will have to be shorted out and it would be better to use a smaller coil. The radiation pattern will not be a bi-directional "figure 8" (as will be true on the lower frequency bands) but rather a figure 8 plus a number of other lobes, many of which will be highly useful, and tend to give coverage in all directions.

In addition, the antenna can be used as a random length long wire (fed with an L network) on 80 meters and 40 meters so the Mini Vee is actually an all-band antenna. All of this can be done with a somewhat more complicated tuner plus a simple switching arrangement. But that is a story for another time – and perhaps the subject of another article!

...WØLBV

Technical Aid Group

Please refer any questions of a technical nature to one of the following members of 73's Technical Aid Group. These are dedicated amateurs who really want to be of help and do so without compensation. Be sure to state your problem clearly and enclose a S.A.S.E. for a reply.

John Allen, K1FWF, high school student, 51 Pine Plain Road, Wellesley, Mass. 02181. HF and VHF antennas, VHF transmitters and converters, AM, SSB, product data, and surplus.

Bert Littlehale, WA1FXS, 47 Cranston Drive, Groton, Conn. 06340. Novice transceivers, test equipment and homebrew projects gone wrong.

Bob Groh WA2CKY, BSEE, 123 Anthony Street, Rochester, New York 14619. Specializes in VHF/UHF solid-state power amplifiers, but will be glad to make comments on any subject.

G. H. Krauss, WA2GFP, BSEE, MSEE, 70-15 175 Street, Flushing, New York 11365. Will answer any questions, dc to microwave, state-of-the-art in all areas of communications circuit design, analysis and use. Offers help in TV, AM, SSB, novice transmitter and receivers, VHF antennas and converters, receivers, semiconductors, test equipment, digital techniques and product data.

Charles Marvin W8WEM, 3112 Lastmer Road, RFD #1, Rock Creek, Ohio 44084. Will help with any general amateur problems.

Stix Borok WB2PFY, high school student, 209-25 18 Avenue, Bayside, New York 11360. Novice help.

PFC Grady Sexton Jr. RA11461755, WA1GTT/DL4, Hedmstedt Spt. Detachment, APO New York 09742. Help with current military gear, information from government Technical Manuals.

Sgt. Michael Hoff WA8TLX, Box 571, 6937th Comm. Gp., APO New York 09665. Help with all types of RTTY both commercial and military. Also data techniques. Covers conversion of military RTTY equipment.

J. J. Marold, WB2TZK, 279 Farmers Ave., Lindenhurst, New York 11757. General.

Ira Kavaler, WA2ZIR, BSEE, 671 East 78 Street, Brooklyn, New York 11236. SSB transmitting, color TV, computer programming and systems, digital radio and remote control, rf transmission lines, dipole design, audio amplifiers, linear and class C rf amplifiers.

Fred Moore, W3WZU, broadcast engineer, 4357 Buckfield Terrace, Trevose, Pa. 19047. Novice transmitters and receivers, HF and VHF antennas, VHF converters, receivers, AM, SSB, semiconductors, mobile test equipment, general, product data, pulse techniques, radio astronomy, bio-medical electronics.

NEW PRODUCTS

Remote Control Relay

Alco's Remote Control Relay is a remote control component that combines a step-down transformer and a sensitive AC relay in a single laminated core that fits in a compact midget size package. It converts a 95-125 VAC power source to 30V that can be run through ordinary surface wiring without shocks and hazards.

Simply plug this relay into any outlet, and it provides the actuating voltage to a 110 VAC alarm or remote control accessory. It has a 3-way receptacle to select a Normally Open or Normally Closed circuit. The side jack serves as a plug-in for the remote switch or sensor.

28 Circuit Ideas Are Free

Our 28 Design Idea Booklet shows circuits on how to build typical remote control circuits of appliances; machine tools; TV commercial killers; fire, smoke and burglar alarms; garage doors; sprinklers—and other apparatus requiring safe, remote control circuits.

For further information, contact Alco Electronic Products, Inc., P.O. Box 1348, Lawrence, Mass. 01843.

Closed-Circuit TV Camera

ATV Research announces the availability of its new line of SOLID-STATE MODULES for building your own TV camera (vidicon type) or for updating existing cameras. Through the use of these wired, pre-tested, encapsulated modules building a complete camera can be accomplished in a single evening. No previous TV knowledge or special test equipment is required.

Modules include: (1) Video module, (2) Vertical sweep module, (3) Horizontal sweep module, (4) RF modulated oscillator module and (5) DC-DC HV module.

Using the first four modules, experimenters and constructors can build a complete TV camera (less power supply). Power requirements include 12V for modules and focus coil, 6V for vidicon filament and 200 volts for the vidicon control circuitry through the use of the (5) module which amplifies and rectifies the horizontal sweep pulses.

These modules are compact, light weight and economically priced from $10 to $20 per module. Each module comes complete with hook-up instructions.

Write ATV Research, Dakota City, NB, 68731.

Mod-U-Line Cabinets

Sorenson Electronics Co. introduces a complete line of electronic cabinets for the builder. Constructed of high strength H-34 hardened aluminum alloy, these cabinets can be twisted, dropped, drilled, punched, and still stand up with no distortion or misalignment of panels. Chip proof baked enamel finish in contrasting grays (other colors are available on special order) is applied over alodined surface. Available in just about any size any builder could want at modest cost. A catalog is available on request from Kaylor Electronic Products, 1918 Menalto Avenue, Menlo Park, California 94025.

The Guerilla

The life of an editor is fraught with many crises. Virtually upon the eve of my wedding day, I received an antenna in the mail. This was for evaluation and review. It comes from Dusina Enterprises of Melbourne, Florida. I have to admit that I asked for it.

In my term as Editor of *73*, I have tried to maintain a high degree of integrity in our advertising. If you look back a year or so, you will find many advertisers in the pages of 73 who no longer appear in the magazine. A few were voluntary "drop-outs." Most of them just didn't meet my rigid standards for honesty in their ads. After receiving complaints from some readers about false and misleading advertising, I began to scrutinize the ads more carefully. We lost a few good old customers in the process.

When an ad came in from Dusina, I was more than skeptical about their claims. I came close to not accepting their ad. I made an agreement that we would run the ad for one month, but I wanted to see the antenna. The antenna arrived on Monday. Tuesday morning dawned, cold and rainy. Being partially editor and partially idiot, I often refer to myself as "Idiotor" of 73. Today I really earned the title. At 10 A.M., I was up the tower at 75 feet tying the center of the "Guerilla" to match my existing dipole. Since the dipole is strictly for 75, and the Guerilla is for 40 *and* 75, I then spent the next hour

and a half cutting another dipole for 40, tying it at the 75 foot level, and tossing rocks at tree limbs to tie up the ends of the whole mess.

I am first of all a woman, I'm also a grandmother (albeit a young one) and have a degree of arthritis in my throwing arm.

By noon I was cold, damp, and tired. I had been up and down the tower four times and had thrown innumerable rocks over numberless branches. I took a martini break and, after checking resonant frequencies on all antennas concerned, started making some on the air tests.

What was I trying to prove? Well, the "Guerilla" is essentially a trapped dipole which claims 50% power gain (2 db) over a conventional dipole. My question was, "How can a dipole have *gain* over a dipole?"

Now, I pride myself on having an efficient antenna system. I am an incurable QRPer. I never run over 100 watts, so if I am going to communicate, I have to do it with the antennas. I consistently get good reports. I do a lot of operating on the top end of 75 meters and compete with kw stations all the time. So, I know my 75 meter dipole is good. At 3.999 my SWR is 1:1. At 3.999 the Guerilla showed 2:1 SWR. A station in Washington, D.C. gave the Guerilla 10 db over my antenna. A station in New Jersey gave it 1 S unit over my dipole, and a station in Buffalo (not in a favorable direction) said both were the same. On 40 meters, the resonant point of both dipoles were much closer, and the Guerilla topped my dipole on every report.

I have not answered the question of how a dipole can have gain over a dipole. For the time, I can only say that the Dusina "Guerilla" does have high efficiency to at least 2 db gain over my conventional dipole.

Basically, the Guerilla is a twin lead folded dipole, fed with twin lead feeders with a built in balun at the transmitter end. The overall length is 120 feet. The feedline is 50 feet. I found it necessary to go to RG58/U coax to reach the shack, but this still looked like 50 ohms at the transmitter. I can only assume the 2 db gain comes from the low loss in the twin lead over a coax feedline of over 100 ft.

The Guerilla comes with green nylon cord, built-in eyelets at the ends of the dipole, and lead weights for throwing over tree limbs. (The rocks were for my 40 meter dipole.) It is lightweight, easy to erect, and works! It is rated to take two kw PEP. The SWR curve is very flat on 40 meters, but has a more pronounced dip at resonance on 75. It is cut for 3.9 and maximum SWR is 2:1 on the phone band.

Available for $33.75 from Dusina Enterprises, 571 Orange Ave. W., Melbourne, Florida.

Modifying a Tube Converter for FET Operation

L. C. Maurer, W6OSA
209 Nob Hill Way
Los Gatos, California

With the advent of VHF FET's, such as the TIS-34, at $1 or under, it becomes practical to remove the tubes from old style converters or receivers and replace them directly with Field Effect Transistors. The unit that I chose for my first experiment along these lines was a rather ancient VHF-152, 10, 6, and 2 converter (see **Fig. 1**). I decided to start with the ten meter band but in order to be certain of having plenty of signals for tests I moved the lower limit down to 11 meters, the C.B.'ers being very active in these parts. A 4 pf capacitor across each of the three ten meter coils did the trick, (dotted lines in **Fig. 2**).

It can be seen from the schematic that the VHF-152 is not wired like a conventional receiver front end. I don't say the VHF-152 is better, just different. Note the 18K resistor which serves as a plate choke for the 6AK5 *rf* amp. Obviously that will have to go before we can substitute an FET for the 6AK5.

Next comes the problem of neutralization. A typical VHF FET has about 1.5 pf capacity between its input and its output as compared with the .02 pf capacity of the 6AK5. There would seem to be two possible routes. Either use a conventional tapped plate (drain) coil and a neutralizing capacitor, or employ 2 FET's in place of the one 6AK5 in a cascode arrangement.

Because of the band switch consideration, it was decided to use the cascode approach. LI will serve as the gate inductance for Q1 and L2 will serve as the drain inductance for Q2. It will be necessary to lift the bottom end of L2 from ground and feed the plus 21 volts through it as in **Fig. 2**.

This particular model converter never did work well on 2 meters. One look at the band change switch will explain why. But, it was thought that the transistorized version would cover 10 and 6 meters in good style. Therefore, the band change switch was preserved. For 2 meter operation, a separate *rf* preamp which I already had on hand (refer to 73 Magazine, July, 1967, page 48) can be wired into the band change switch as shown in **Fig. 2**.

Because this was my first attempt at con-

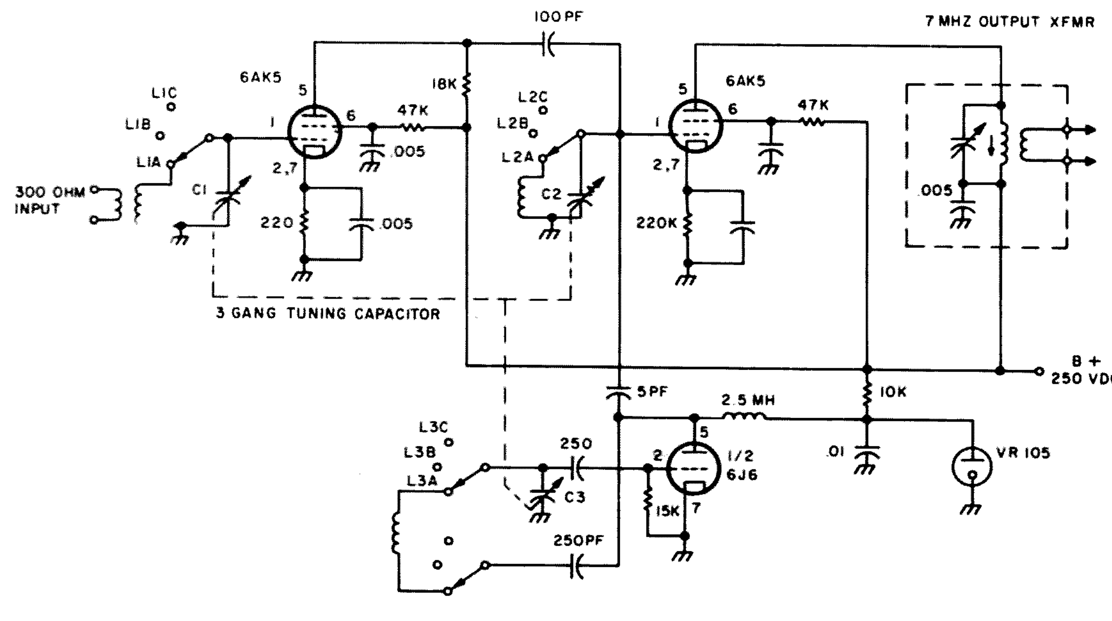

Fig. 1. Schematic for the 10, 6 & 2 converter.

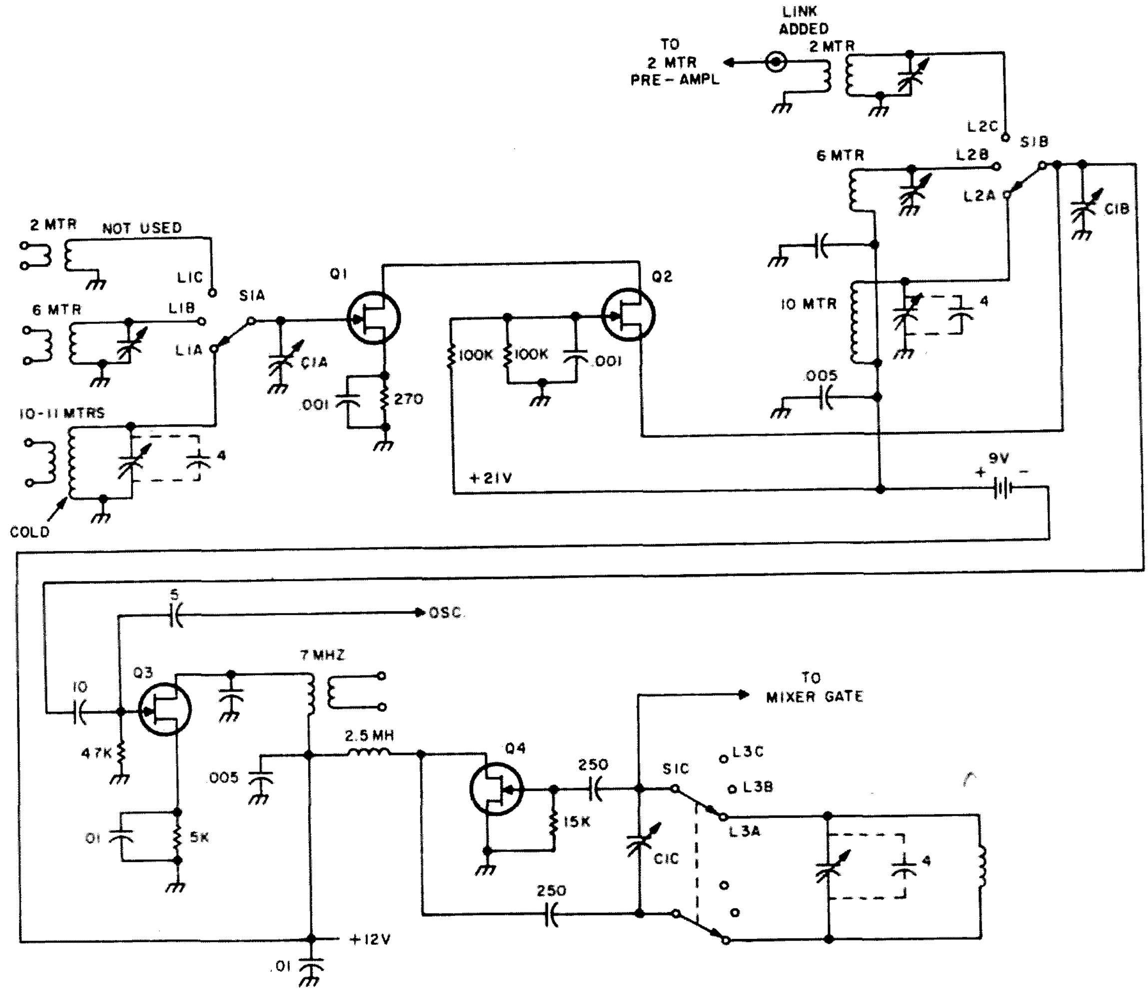

Fig. 2. Modification to FET.

verting from tubes to FET's, I used a cautious three-step approach. The idea being that if something didn't work, I would have a better idea where to look for the trouble. The 6J6 oscillator tube was removed first and a TIS-34 soldered to pins 2, 5 and 7 of the tube socket. I had expected that the injection voltage from the new FET oscillator might be a little low for a tube mixer but this did not seem to follow. The converter worked as well as ever with improved stability.

Next, I removed the 6AK5 mixer and soldered another TIS-34 to pins 1, 5 and 7 on the mixer tube socket. It was necessary to change the grid leak and cathode (source) bias resistors. Operating again as a hybrid with two FET's and the 6AK5 *rf* amp., the old VHF-152 performed better than it ever had in its life. I was almost tempted to "leave well enough alone."

The final step was to remove the 6AK5 *rf* amp and replace the tube with two FET's. In this type of cascode circuit, the FET's are in series so it is desirable to increase the voltage to some value between 18 and 24 volts. What I actually did was to add a small 9 volt transistor battery in series with my 12 volt regulated power supply. In the original VHF-152 circuit, the bottom of L2 was grounded (refer to Fig. 1). It was merely necessary to lift the ground, bypass it, and supply the 21 volts as shown in Fig. 2. The ideal situation would be to have the voltage drop across Q1 and Q2 approximately equal. If you use transistor sockets, you might try swapping Q1 and Q2 back and forth to get the best arrangement. The gain of the stage is determined almost entirely by Q1. You can even use an NPN bipolar transistor such as the 2N706 for Q2 if you wish. The voltage divider for the base bias should consist of two 6K resistors instead of the pair of 100K resistors shown in Fig. 2. No other change is necessary.

Now comes the part that is a real pleasure. The power transformer, choke, rectifier tube and VR tube can be removed from the VHF-152 chassis and deposited in the junk box. The new VHF-152 is ten pounds lighter than

DX Quiz . . . Answers

Here are the answers to the country quiz on page 56.

1M4	Minerva Reef*	7G1	Republic of Guinea
1S9	Spratley Island*	7P8	Lesotho
		8F4	Indonesia

5R8	Malagasy Republic**		
5T	Mauritania	9M2	West Malasia
5U7	Niger		
		9X5	Rwanda
		9Y4	Trinidad & Tobago

*As far as we know, no operator has legitimately operated from these countries as yet.
**Madagascar is not correct.

the old one used to be. It is more stable and its signal to noise ratio is improved. It can be operated entirely from small inexpensive batteries if desired.

Although the above remarks appear to be aimed entirely at the VHF-152, I want to emphasize that any converter, or receiver front end for that matter, can be converted to FET operation by following the same basic procedure. One word of caution; if you use the step by step approach, be sure to remove all wiring from the "B" plus 250 volt supply which might come in contact with the new FET before attempting to operate in the hybrid mode. Also, be careful about the battery polarity. It is sudden death to reverse the battery on an FET stage.

The TIS-34 is an N-channel FET and there are several other types which would no doubt work equally well. Make certain that the one you select is rated to operate at the highest frequency that you intend to operate the converter. A bipolar transistor can certainly be used in the oscillator stage. I don't recommend bipolars for Q1 or for the mixer stage because I like to preserve the hi-Q and image rejection of the tuned circuits in LI and L2. It would be difficult to tap down on these coils due to the band change switch.

...W6OSA

(...de W2NSD/1 continued from page 2)
stay CB'ers...or Technicians. Keep after them. Get them into your club and keep them coming to meetings. We've certainly published enough information on how to make club meetings interesting and valuable so you have no excuse for letting your club fail.

The United States twenty years from now will reflect the interest and effort that *you* show today. Electronics will be reaching into every aspect of life then. Schools will be using computers and television more than we even envisage today. Communications satellites will put every home and business in instant touch. Every person, for that matter, may well have a personal phone right with him at all times. Well...almost all times. Credit cards may be used for even the smallest purchases. Just stick it in the slot and your account will be debited from anywhere in the country.

Both on the military and economic fronts, the strength of our country in the future will depend heavily on electronics. We have a lead right now, but can we hold it? You know darned well that Russia is aware of this for they are organizing amateur radio on a level that is leaving us behind. They emphasize the fun over there. They have elevated amateur radio fox hunts to a national craze, with regional championships and then enter national championships. Thousands of clubs participate in this.

In a large measure the future of the country is in your hands. If you have a club, get it into action. If you have no club in your area then start one. If you can't do that, elect yourself a committee of one to go to your local high school and sell ham radio. Get those classes started. Call the school principal today and see if you can arrange to bring down some equipment and QSL cards for a talk in assembly or to the science classes. You certainly can take one night a week off for an hour or two of classes. Or even a Saturday?

...Wayne

Ham Hospitality

Some years ago an organization sprung up in Europe called the Ham Hop Club. The basic idea of this club was a good one, but the effort floundered as the paperwork grew with the size of the club and no one could be found to do the work for no fee.

The Ham Hop Club was set up to enable hams visiting other countries to meet and stay with the local hams. The club, on getting a copy of your itinerary, would. write to members in the countries you planned to visit and arrange accommodations for you. This was a lot of work and took a lot of time.

I made very interesting personal contacts in Paris, Rotterdam, Amsterdam, and other cities as a result of the club, though I preferred to use hotel accommodations rather than put people out with overnight visits. It was through the Ham Hop Club that I met Pierre, F2BO, who later came to New Hampshire to work at 73 and went on to successful work at the University of New Hampshire.

In almost all of the 80 countries that I have visited so far I have been met and entertained by hams. I can testify that ham hospitality is first rate. For some time now I've been wondering what I might be able to do to help get local hams together with visitors. Setting up an office like the Ham Hop Club was obviously out of the question. Perhaps I now have an idea that will work. It seems worth a try.

It has been my experience that when I visit DX amateurs that I benefit tremendously. First of all, the warm welcome makes the city or country seem much more friendly. Secondly, my host is able to explain the customs and mores of the people so that I can understand them. Thirdly, I love to try new foods and often I am treated to a dinner of local specialties which are exciting and fun. In return I find that there are an almost infinite number of questions about the United States that are waiting to be answered. Foreigners read about us all the time, but they have no way of knowing how we look at and understand our own country. They want to know about how our people really feel about the racial problems...Vietnam...how we think of their country, etc. What do we think about our changing morality...big business...politics ...revolt. They want to know about all of those things that QST says you shouldn't talk about on the air.

The DX amateurs that I have visited and talked with seem most enthusiastic about entertaining us W's. I might just offer a warning though that invitations be worded explicitly. I have known U.S. amateurs to accept carelessly offered hospitality by turning up with wife and two children, hitch hiking with full back packs, intending to stay for some weeks.

It seems worth while to me for us to make a try at getting hosts and travelers together through the pages of 73. If you are interested

in extending hospitality to a visiting amateur, write and let us know the details of your offer. We will in turn publish it, and from there on it will be between you and the travelers. Please keep your Ham Hospitality notices brief. I suggest you start with your city and state or city and country for DX. U.S. amateurs should specify DX or W/DX. Specify OM/XYL/children. Few families do much traveling with their children, but if kids would spoil the visit just say OM/XYL. If you and your wife have any other interests you might list them...travel, photography, skiing, occult, etc. Give your address and phone number. Users of our Ham Hospitality service will be requested to write or call as much ahead of time as possible and to recognize that all of us have plans that we don't want to break and that all offers are contingent upon the time being open. Try and keep your offer to 30 words or less please.

Sample:

Peterborough, NH. DX OM/XYL, overnight/dinner, local sightseeing and rag chewing. Interests: travel, photography, skiing, skin diving, Mensa, art, occult, UFO's. Wayne Green W2NSD/1, Peterborough NH 03458. 603-924-3873.

Gentlemen's Agreement

Many AM holdouts on our 20M band keep bringing up a "gentlemen's agreement" which guarantees them permanent exclusive use of lower half of the 20M phone band. For the information of those of you who have entered amateur radio during the last ten years, there was indeed at one time such an agreement.

Back in the early years of sideband the pioneers were not interested in working DX. Indeed, attempts at it were rather futile, since very few DX operators even had an idea of how to tune in a sideband signal. I remember visiting OE1ER in Vienna back in 1958 and finding that he was under the impression that his receiver (AR-88) wouldn't tune in sideband. I showed him the technique and broke in on my good friend W2CFT, calling on AM. Al said hello to us immediately and it wasn't many moons before OE1ER was heard with a rather potent sideband signal.

Since they couldn't work DX, most of the sidebanders congregated on the non-DX end of 20M, the high end. At first they took up the top 20 kHz (they were kc in those days, alas). Then, as more fellows found out about the advantages of SSB, they gradually expanded...30 kHz...40...50! At about this time, the phone band was extended from 14.3 to 14.35 and the SSB crew filled the 14.25-14.35 segment almost immediately, leaving the 14.2-14.25 segment for AM.

But by now more and more DX stations were getting into the act and learning how to work the sideband stations. And even worse, from the AM point of view, every now and then a DX station would change over to SSB. Even the unthinkable happened...a DXpedition operating on SSB instead of AM! The sidebanders found that they had to tune up on the low end of the band to work these DX stations and that was when the gentlemen's agreement went out the window.

With some intelligent leadership the AM'ers might have rescued the situation for themselves by regrouping on the high end of the band. Their opportunities for working DX were fading away and there really was no good reason for sticking to the low end other than stubborness.

Unfortunately for the health of our hobby, the same personality traits that kept fellows sticking to AM when the rest of the world was changing to sideband, also kept them on the air bitching about things and generally trying to make as much of trouble as they could. This, of course, does not apply to all AM ops, but it does to enough for us to make a good general case.

When I operate I try very hard to be as polite and helpful as I can. Sometimes, I feel quite a strain and I discover that I feel like quitting for a while. I wonder if it is really necessary for us to make it so difficult for the FCC to take the licenses away from fellows who have serious psychological problems and insist on venting them on the air.

I digress; as usual.

Perhaps it is time for us to initiate a new "gentlemen's agreement" for the AM'ers on 20M. It would make life a lot easier for them...and certainly for the rest of the resident 20M ops, if they started working from the 14.35 end of the band, as the SSB'ers did when they were as rare as the AM ops are today. I'm open to any good reasonable arguments for or against this...but if you find yourself hot under the collar, wait until you cool off and can write an intelligent and well thought out letter which will be of interest and value to us all. We have enough emotional harangues on the air and they are not needed in print.

Z-1000 Certificate?

Would there be any interest in a new type of certificate? I have in mind something the

reverse of the A-1 Op certificate. Should we have some permanent memento that we can send to ops who demonstrate on the air their stupidity, their thoughtlessness, their lack of consideration for others, and other lousy characteristics which go to sour the average amateur?

A nice big certificate, edged in black, could be sent to any operator who has made such an ass of himself that a bonafide amateur radio club has taken the effort to submit an official censure memorandum to us. We could then issue the certificate, printing the detailed complaint on it and the calls of the club members who have lodged the complaint. We might also send a copy to the local FCC office for their information.

What is your reaction to this? If you don't like the idea, what can you offer as a positive suggestion that we might all be able to do to help straighten out these either thoughtless or "sick" ops that are botching things up?

Wayne

Covers?

We need interesting and colorful covers for 73. Perhaps some of our readers are artists and can paint some good covers? Or can you photographers come up with some cover ideas that will help us sell more magazines on the newsstand? Our newsstand distributor is most adament that we should have a person on the cover as well as equipment, parts, a tower, or whatever. And if this person happens to be gorgeous so much the better.

Keep in mind the aspect ratio of our cover format. We can vary from this, but we tend not to. We can work from color slides of the regular 35mm type, or from larger color positives or negatives. We can work from color enlargements too. And of course we can work from original oil or watercolor paintings or pastels. Paintings should be about three times the finished size.

Cover ideas are hard to come by, so see what you can come up with. Remember that we run special issues now and then devoted to surplus, antennas, vhf, dx, transmitters, receivers, and such. RTTY, ham-tv slow-scan tv, moonbounce, dishes, and other ham developments are all worth while for covers.

We are paying a fortune to reprint color pictures on the cover so be sure that your entries are colorful...have good composition ...and are sharp and clear.

FCC Action

Perhaps "action" is an exaggeration. At any rate the FCC on March 11th announced that they had extended the time for receipt of comments on the petition by John Attaway, K4IIF, to hold up on extending the Extra Class CW bands on November 22nd since the present allocations had yet to be adequately used. The extension was until April 7th. Since the next possible issue of 73 that we could get the news of this extension in would not be in the hands of readers until April 25th or so, we did not fall all over ourselves to get this notice into print.

If you feel that the FCC is rushing things a little with their intention of opening up another 25 khz to the Extra Class for CW, come November this year you might sit down at a typewriter and compose your thoughts on the matter, giving all of the arguments you can think of to back up your proposals. Address these to the Secretary of the FCC, Washington, D.C. 20554, and send along the usual 15 copies to make it official. It does not hurt to get a notary on the original copy.

The FCC will continue to slough us off as long as we remain disinterested enough in our own fate to keep our opinions to ourselves. If the FCC doesn't get any more mail than I do about these things then they are absolutely right in dismissing us as unworthy of much consideration. If anybody cares much about what is going on they are keeping mighty quiet about it. The squeaking wheel gets greased. Office copiers are just about everywhere now so there is little excuse in not making up those silly 15 copies and filing your opinions officially.

Wayne

Ontario QSO Party

All amateurs are invited to participate in the Ontario QSO party sponsored by the Radio Society of Ontario, Inc. The contest will run for a 31-hour period from 1700Z July 19, to 2400Z July 20. There are no power or band restrictions. Ontario stations score 1 point per contact and multiply by the number of ARRL sections and foreign countries worked. Others score 3 points for each Ontario station and multiply by the number of countries worked on each band. Ontario stations send QSO number, report and county. Others send QSO number, report and section. Logs must be postmarked no later than August 31, 1969, and sent to: Contest Chairman, Radio Society of Ontario, Inc., P. O. Box 334, Toronto 18, Ontario.

LETTERS

Last year, at renewal, I wrote a somewhat critical note stating that I thought the quality of 73 had degraded. As you can see by my 3-year renewal I don't feel that way anymore. Although I do believe that your magazine is not as "good" as it was 2-3 years ago—I think it's improving qualitatively issue by issue.

I would like to give you some of my thoughts regarding the state of amateur radio.

First of all, after I received my latest renewal from ARRL-*QST*, I decided the hell to the ARRL. I am discouraged Wayne, that a bunch of 70 year olds—living in a consciousness of the 1940's (at best)—are trying to run a (the) ham radio organization and amateur radio itself. When I read those assinine editorials—as I have in the last few issues of *QST*—about restricting freedom of speech on the air to nice safe, non-controversial topics I become upset for the future of our hobby. As you are well aware, the average QSO is the most repulsively dull conversation imagineable. Further, I am discouraged that these same 70 year olds—with the help of many fuddy-duddy engineer types—railroaded thru that damn incentive licensing giving the granddaddies lots of privileges and effectively "wasting" the lower 25kc of our bands (listen how void they are of use). Third, I am discouraged about the racism that I hear on the air and that I sense when I meet fellow hams. Amateur radio appears to me to be one of the most segregated hobbies in American culture. At a time when our hobby is hovering near increasingly faster (sharper) declines in new applicants—and perhaps air space—we should go to Boys' clubs, etc., in the inner cities and help set up at least club stations. But I sense that many hams are afraid that such communication potential may be used in riots for other than avocational purposes—such a ridiculous argument presumes of course that other forms of two way communication are not available—and they are. But, I guess that the real reason inner city kids are not introduced is because hams are fuddy-duddy—old and mainly traditional, solidly middle class, and scared. (Lack of equipment availability I do not see as a problem.) In fact, if you peruse the pages of *QST* you see lots of lines devoted to trivia, i.e., what Joe Ham is doing in the Midwest section with his new Drake Line, etc., or gobs of stuff on that puffed up public service bit called civil defense (excepting natural disasters), but little of social significance.

And, yes, Wayne, even you have been quiet on the turmoil in our society—focussing instead on safe stuff like USO nets, etc.

At a time when long distance telephone rates are cheap, telephone accessibility is so widespread there is little public service left that hams do, excepting certain overseas patches. Traffic is a slow farce; civil defense can be better (and has been) handled by CB'rs; and contributions to the electronics industry and our national defense is a delusion we allow ourselves but which is actually groundless when one considers how laggardly the state of ham technology (homebrew) is and how few young people participate in our hobby.

All in all—hams need a good kick in the butt, and probably deserve to lose frequency space considering the outmodedness of our hobby.

Gerhard J. Hanneman, WA8VBN
Michigan State University
East Lansing, Michigan 48823

While I am unhappily acknowledging Kayla's happiness, I will take the opportunity to say I'm sorry to know you are losing such a fine editor. She has a unique way of putting a feeling of friendship into "73." I suppose it is achieved simply by being friendly. She will be missed.

I am very glad to learn from your editorial how well you have succeeded with "73" in so short a time. You are to be congratulated, indeed. I rather doubt that it is getting too big for you as I am sure you are growing with it and are capable of handling its future growth, which, I hope, will be somewhat more than considerable.

While I am at it, toss my thanks to Zaranski for his article, "Minimum Cost Semiconductor Survey."

Also, I have for a long time wanted to thank Robert Suding for his article, "A Cheap and Easy Frequency Counter," November "73," 1967. I note in the current issue of "73" "Looking Back," refers to Votipka's counter, Nov. 1968 as being "over-simplified," and difficult to build. As I am about to revise my counter constructed from Suding's article with a few modifications, such as wave former and input gate and reading for one second, displaying one second, then repeating to update, I would appreciate it if you will use the enclosed SASE to forward the material mentioned on Votipka's counter (Nov. 1968).

If I recall corrently there was one omission but no errors in Suding's article, which remains the simplest and cheapest counter I have seen to date. It worked perfectly the first time I connected it up.

Again, congratulations on your excellent publication, the excellence of which its growth will continue to show. And, again, my regrets that the world, you and me, have lost our fond "Editorial Liberties."

C. W. Pate
Bryte, California

I know letters like this must be a pain, but if you would print this, I would appreciate it. It's to ask if there are any Swedish or English hams with whom I could exchange correspondence, cause om-a-goin' there. Naturally I would like them to be near my age (17), and longhairs, (you know, radical trouble-making whipper-snappers like I obviously must be). I write to you because of all the magazines, yours seems to have the readership with the largest number of people like me. I mean that as a compliment, you know. Thank you.

Richard Klein, WB22TN
(Sorry, can't help you leftist fellow-travelers—ed.)

Your March 69 issue of 73 *Magazine* was especially pleasing to me. The W1EMV and W2NSD/1 editorials continue to be outstanding; however, it was a most pleasant surprise to find an *open letter* to the editor by our old friend, A. David Middelton, W7ZC (page 71). In his typical straight-from-the-shoulder style, without repetitious "gobbly-gook," Dave conveyed his message to the reader. To the best of my memory this is the first public article by W7ZC I have seen in almost five years. What a void to hamdom!

I am appalled by the inactivity or loss of so many fine writers and club editors. In the past five years and particularly since the questionable "Incentive" Licensing action there has been a definite lack of controversial articles and "think" items for the amateur radio readers. As the result, amateur radio is suffering immeasurably by this loss of material. Since the innovation of the "incentive" ruling, radio amateurs are resorting to small independent cliques, uninterested in the overall picture because they have been subjected to one-sided information, or worse—no opinions at all!

During the promotional years of supporting amateur radio reciprocal licensing in this country, readers consistently found numerous excellent debatable reading matter in several magazines and club bulletins (but very few ever appeared in QST, I might add). These were the product of a great number of quality writers, many of whom were non-professional, but who have since chosen to remain dormant or have totally given up crusading in behalf of hamdom.

DX Magazine from Burlington, Kentucky, and The Monitor from Dallas, Texas, topped a long list of excellent periodicals, most of which have been discontinued. The Kentucky publication, edited by Don Chesser, W4KVX, and assistant editor Bob Knapp, W4OMW, was eagerly read by every *thinking* radio amateur. This same keen interest was directed to The Monitor, edited by courageous Joe Martin, W5RYP, and his talented staff of associate editors J. Foy Guin, W4RLS, A. David Middelton, W7ZC/W5CA, and Len Collett, KZ5LC; Oklahoma Editor, Doris Anderson, K5BNQ; Indiana Editor, Phil Hunsberger, K9PNT; Maryland Editor, Mari-Anne Payton, W3LQY; Nevada Editor, Leonard Norman, W7PBV; Circuit Board Editor, Walter Stevens, K5ICV; Virginia Editor, Van Wimmer, WA4BIX; Texas Panhandle Editor, Phil Patterson, W5SFW; and Mississippi Editor, Eddie Livingston, K5VOK.

The Institute of Amateur Radio, Inc. (IOAR), offered the hams outstanding "think" material by two well-informed writers: Wayne Green, W2NSD/1, and A. David Middelton, W7ZC. Dave also served for a time as the secretary of IOAR. Although sorely needed by all of hamdom, radio amateurs did not have the foresight nor the capacity to discriminate between facts and personalities—with the drastic result that the organization was not sufficiently financially supported. To concurring hams this meant that a sound and effective program was temporarily shelved. The Institute is amateur radio's solution to provide a much needed legitimate lobby in Washington, D.C. My personal opinion is that IOAR, properly supported will furnish the healthy competition required to "force" ARRL into providing a true democratic representation for its members and USA amateur radio. Reactivated and strongly assisted, the Institute of Amateur Radio can still provide the necessary liaison and lobby in our Nation's capital, a function vitally needed to improve and correct our present serious deficiencies. The end result will provide Congress and the amateurs with immediate factual and current information relative to Stateside as well as world-wide amateur radio activities.

You may remember other excellent writers during the pre-incentive licensing era: Dorothy Strauber, K2MGE/W4MYE, assisted by her energetic OM Irving, K2HEA, who edited The Sidebanders, published by the Single Sideband Amateur Radio Association. (Dotty also had a column going in CQ Magazine.) That vigorous staff included Ralph Mason, DL4PI; Harriet "Sunny" Woehst, K5BJU, as the YL Editor; Phil Carter, W1CRA; and James L. McCoy, K5GCE, who wrote under the by-line of "The Real McCoy."

From Europe came the extremely provocative articles of the very talented Frank E. Mortensen, W7HNT/WA6YNG, under his by-line "Let's Be Frank" which appeared in the SARA STATIC issues of the Spanish-American Radio Amateurs in Sevilla, Spain, and the QRZ bulletins of the Bitburg, (Germany) Amateur Radio Club. Both of these club periodicals were widely distributed world-wide. Frank's articles were directly responsible for the tremendous world support that resulted in the eventual passage of the reciprocal licensing bill into law.

What has happened to these fine writers? What has discouraged them from submitting timely articles? There are sufficient problems in today's USA amateur radio sphere to warrant and attract the controversial/think writers. Could it be our lack of interest? Least you forget, amateur radio owes a great deal of its development and progress to the polemical and "think" pieces from well-versed and qualified personnel whose written opinions over the years gave each of us the necessary background to weigh, with an open mind, the dialogue needed to reach a valid and realistic decision. Those writers, plus many more unmentioned in these comments, recognized the need during that period to provide hamdom with varied open-minded opinions.

Today, more than ever, amateur radio should find a place for the opinionated thoughts of its writers. Too, there is a place for the reporter-type who can publish in his own town or city newspapers or commercial magazines, the amateur radio events as they happen. But, primarily we need to recall all of those authors who, by writing their own thoughts can make us more knowledgeable and conscious of what is happening to amateur radio in our country. We must be shocked into thinking and acting immediately! This is no time to waste on those writers who are fearful of "rocking the boat."

I hope to see more inputs from David Middelton. Perhaps he can awaken the interest of those dormant authors. There are many of us who want to see their articles in the pages of our favorite magazines and other periodicals. With the continued absence of the journalistic efforts of qualified controversial/"think" writers, the USA radio amateurs cannot expect any improvement in present conditions—in fact, we will continue to live with token "representation" and degradation that is occurring in our ranks. Too, we must be cautious of accepting the opinions of "self-styled" journalists who author the "expert" overseas picture after one short visit to a foreign land. In the eyes of our DX friends, these writers create more serious harm than good. Instead, let us encourage those fine experienced penmen into reactivating their efforts in order that we may regain the courage to correct our own problems. Whether or not we recognize it, amateur ra-

dio in this country today is in greater jeopardy of surviving than ever before!

John F. Barrows, W6ECS
Fairfield, California 94533

I am a great fan of your magazine and wouldn't trade it for anything. But, for a long time I have wondered why you haven't started your own Field Day Contest. I feel this would help a lot of people to like the magazine a bit better. So, keep up the good work and think about this. You have a lot of good articles on contests, but you don't have any contests to use them on that I know of.

David Brittenham, WAØRVK
Monett, Missouri

No, no contests. Somehow we had the feeling that perhaps there already were enough contests. However, if a major radio club would be interested in volunteering to run a new type of field day event, complete with the scoring of the logs, we might just consider it. We had in mind a contest which would be short and unannounced to simulate emergency conditions...ed.

I think your technical articles are great. If possible, more on conversion of commercial FM gear in the VHF range (6M & 2M).

I am an E.T. by profession and rate 73 Magazine as high as any trade or hobby magazine on the market today.

Many thanks to all the fine engineering people who contribute articles in laymen terms.

S. L. Thompson, WA5NXT/Ø

One of the finest articles on antennas ever carried in any magazine was in the April 1966 edition of 73, by Robert Cooper, *Ascendency Curve Yagi*, p. 20. I built a 3EL Yagi for 20M based on his maximum gain curves and it was far superior to commercial beams. How 'bout an article dealing with Maximum Gain for Quads–element spacing lengths, etc. Keep up the good work.

Greg Milnes
Hillsboro, Oregon

I saw it first in your 73 Magazine in November 1966 on page 52. Next it shows up in "ham radio" for April 1969 on page 34, three years later. Can they get a patent on that?

I Am Curious

Dear Curious: Nothing to turn yellow over. W2-WLR does seem to have managed to rediscover a diversity antenna very close to that described by W4TDI in 1966. These have been popular for many years for point-to-point communications where fading is a problem (RTTY, etc.). The low angle radiation is deceptive in high sunspot times when signal reports can be most exciting from areas where the band is just opening. Unfortunately, once the band is open, a very low angle antenna will lose your signal in the qrm. Ask anyone using that most remarkable low angle Twin Three (or ZL-Special) antenna what happens after the band is open or when the sun spots are gone. When "ham radio" announced the W2WLR antenna for their April issue I thought that this was appropos and fought off the strong temptation to discuss it in our April issue.

Here are a couple of photos of my ham TV station which I spent about five years constructing and working out the bugs so now I have a *snow-free* picture up to seventy miles from here. More later, if you are interested. However, I will mention a few stations I work very often and always snow-free in any kind of weather such as K8TME, Damascus, O., WA8DZS, Mount Union, Ohio and also WA8-OKS, same QTH, K8EWX north of Alliance, K8WMA south of Alliance. All of us really appreciate your interest in ham TV but would like to see much more on TV in 73 from other successful TV'ers. Obviously, this is the coming mode in many amateur stations in USA. I think this is the King of all electronic hobbies. Sure is terrifically thrilling. By all means, keep up the good work in your 73 or we ATV'ers might have to throw in the sponge.

Les Miller, W8ACH
Alliance, Ohio

I would like to thank you for a job well done on "Amateur Radio Knows No Borders." It is this type of report that makes me proud to be a member of the amateur fraternity.

J. Stoutenburgh, WNØWDX
Minneapolis, Minnesota

An item of interest for your magazine is the fact that both houses of the Alaska State Legislature have passed by an overwhelming vote House Bill No. 103 which relates to the annual license tax on vehicles containing mobile amateur radio stations. Under the new law, rather than pay $30.00 for a license plate, an amateur holding an FCC license and with mobile capability of 75 meters through 10 meters may obtain his license and his call letter license plates for a total fee of $1.

The idea behind the Bill was to encourage amateur radio operators to equip for emergency use. You will recall that in the case of the Anchorage earthquake in 1964 and the Fairbanks flood in 1967, the power was off and regular communications were completely disrupted for a substantial period of time. In both cases radio amateurs provided an emergency link-up until power and normal communications were restored. In these days of zoning regulations which cramp amateur radio, TVI complaints and million dollar lawsuits, it is heartwarming to see the policy of a sovereign state of the Union recognizing the unique capabilities of the amateur radio fraternity, and I think an appropriate article in your magazine might well be an eye-opener for other parts of the nation. Truly, the entire country should support the principle set forth in Alaska's House Bill No. 103 for no one is completely safe from natural disasters.

Douglas L. Gregg, KL7FPA
Juneau, Alaska

The TIS34 is popular in Amateur construction projects, but is hard to locate "over the counter." It is available from TI Supply Company, 6000 Denton Drive, Dallas, Texas 75235, as a 2N5248/TIS34. The present price for 100 units is $1.10 each.

A Variable Resistance VFO for 6 or 2

Roger H. Taylor, K9ALD
281 William Street
Champaign, Illinois

Another Stable VFO

Voltage tuned variable capacitance diodes have been with us for almost ten years. They have been featured in a few general applications articles, and they are showing up in a few commercial SSB transceivers. However for being such useful little animals, they have seen very little use in ham articles. A considerable effort is made in vfo designs to provide mechanical rigidity in the tunable element, whether coil or capacitor. Yet, here is a completely rigid device which has seen little application. Obviously, what follows is a vfo using the voltage tuned variable capacity diode, and also an encapsulated coil to eliminate mechanical problems.

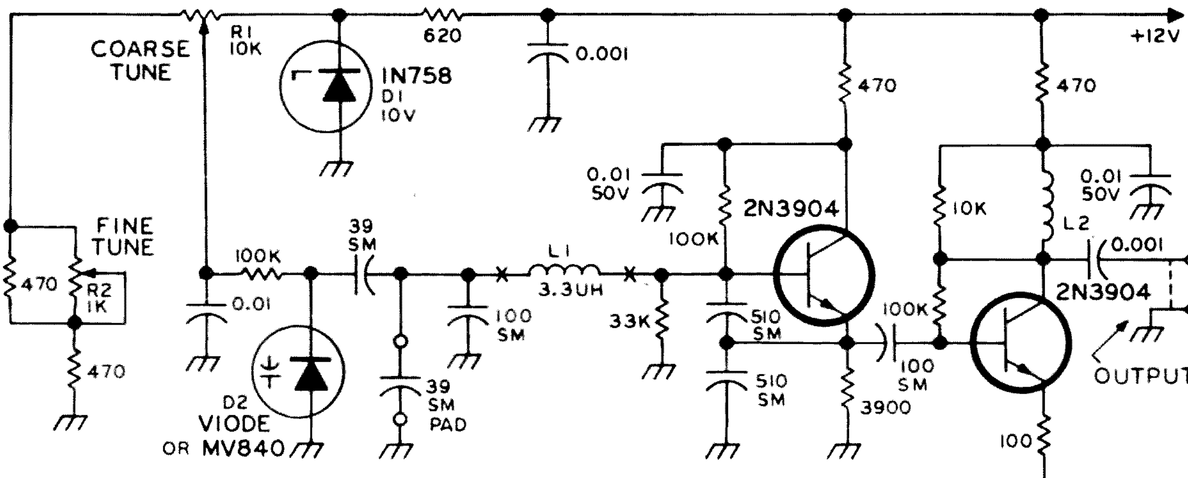

Fig.1. Schematic diagram, Colpitts oscillator.

Two models of the vfo were constructed. One features two miniature potentiometers for coarse and fine tuning. The other has only one standard, a lower cost pot. for the economy minded. The circuits are identical except for the added pot. The schematic shows the standard series tuned colpitts os-

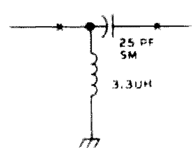

Fig.2. Parallel tuned version.

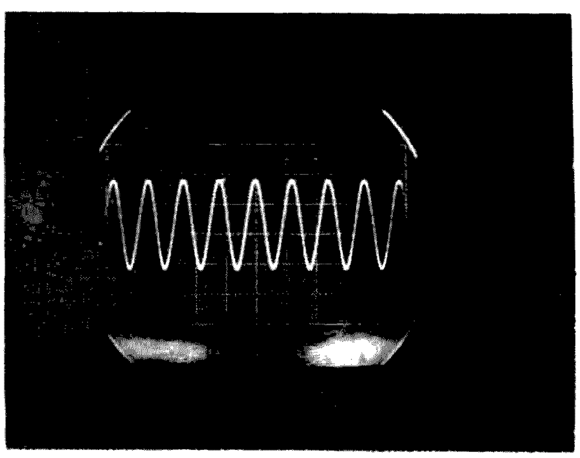
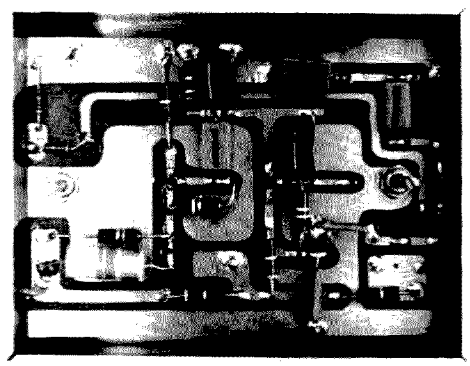


Look at those nice sine waves.



Bottom view.

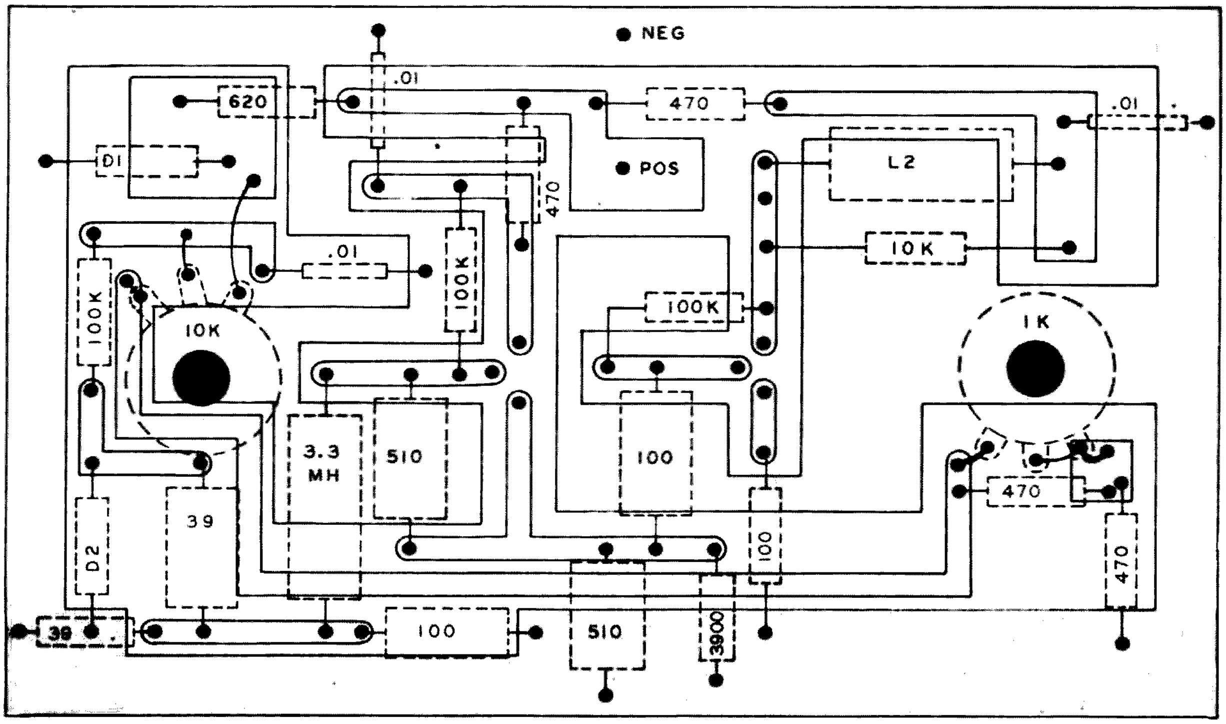


Fig.3. One side of printed circuit board.

cillator in **Fig. 1**. If you prefer the parallel tuned version, simply modify it according to **Fig. 2**. The series tuned version seemed to give slightly better stability with supply voltage variation.

The voltage to the diode is regulated by the zener diode. The .001 capacitor is for filtering any ac or noise. It could be almost any value. The 100K resistor is for isolation of the diode. An rf choke could be used, but would introduce more reactive components into the critical tuned circuit. The output coil, L_2, is chosen to resonate with the length of coax to the next stage. If no coax is used, 15 uH is the correct value. If maximum output is desired, a smaller coil can be used and a trimmer capacitor added to tune the output rather than cut and try on the coax length. The 10K resistor across the output just loads it and broadens the response. The output should be at least 15 volts peak to peak into 10K ohms of good clean sinewave (unlike some other vfo's).

The values given are for a frequency of 8.3 to 8.5 MHz. Changing the padder quickly puts it in the two meter range from 8.0 to 8.2 MHz. The unit is quite stable with voltage variation from 10.4 to 15 volts or more. You can shut the oscillator off in several ways such as: grounding the base, opening the emitter, or simply switching off the supply voltage. Normally the latter is not too satisfactory, but no turn-on drift could be detected. Everything is rigidly mounted to the pc board. The components should be mounted on the back for easier soldering. I mounted most of them on the front to show their placement better.

The two pot. model is recommended for SSB since it is easier to zero beat, or the one

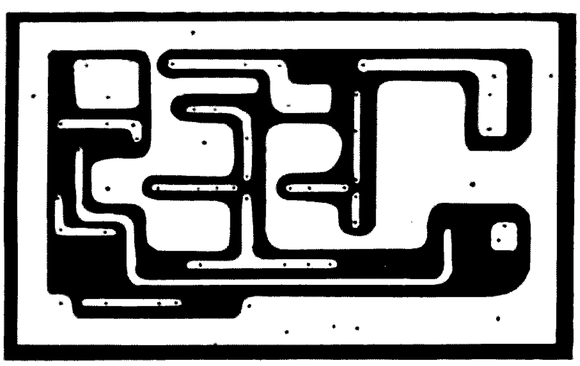

Fig.4. Parts mount on one side of board.

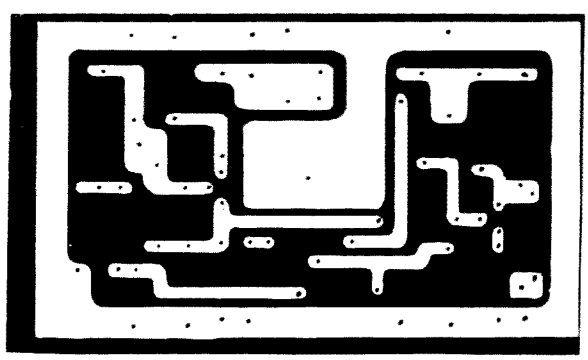

Fig.5. Other side of board.

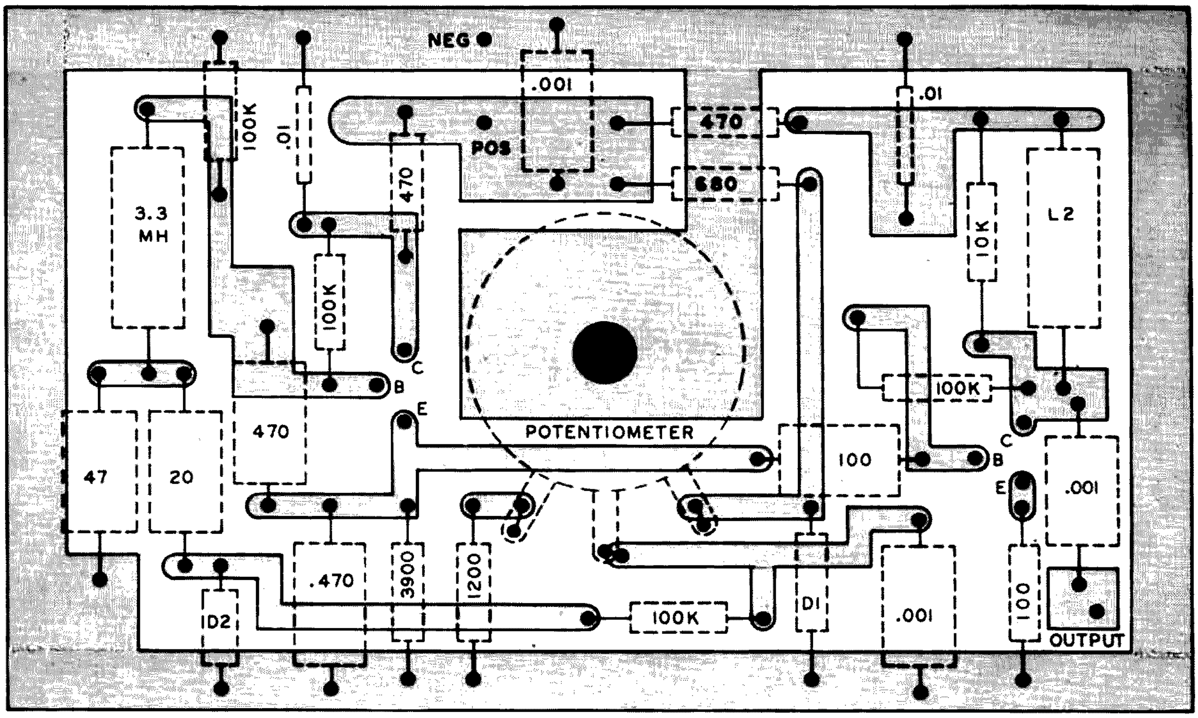

Fig.6. Parts placement on other side.

pot. version can be used with a vernier. You can make a vernier from the tuning capacitor in the "lunch boxes" or Lincoln transceivers. Lafayette also has a vernier (69 cents) on page 291 of their '66 catalog. Using most verniers will restrict you to 180 degrees rotation, while the pot. will provide 270 degrees. The single pot. is quite adequate for AM work without the vernier, and is considerably cheaper. ...K9ALD

Report from the Board of Health

TVI traceable to 6 meters and channel 2 can be difficult and it takes a little time to get rid of it. Sometimes it is incurable. But, TVI caused by 10 meter radiation interfering with channel 2 is hardly ever difficult to control. A trap known as the half-wave filter is illustrated. The components specified allow its use with transmitters up to approximately 500 watts pep output and the capacitors are most susceptible; especially if vswr is above 1.5:1. The formula for calculating safe voltage ratings for the capacitors is: $C = \sqrt{2PxZ_0}$ where 2P is twice power output and Z_0 the transmission line impedance.

There are hams who are off the air because of TVI, and it is not necessary since the filter will provide at least 30 db attenuation for the attenuation for the second harmonic and greater attenuation for the third, etc.

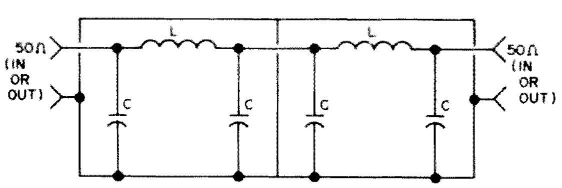

Fig. 1. A half wave filter for TVI.

Parts list:

C: 100 pf mica or ceramic "dogbone," 500 v–(up to 500 watt pep).

L: 5 turns 3/4" diameter self-supporting coil or tailor-made coil stock. Leave a partial turn for knifing to set desired center frequency with GDO; usually 28.6 mhz.

Box: 2¼"x2¼"x5" (more or less) with center partition. Make a small hole in the center partition for coupling the two sections, but don't use a feed-through by-pass.

Ray Stellhorn, WAØNEA

Official ARRL Bulletin 211

With the coming of the travel season amateurs will be taking advantage of reciprocal operating agreements. Amateurs traveling across the Canadian United States border should apply for an operating permit 30 to 40 days in advance. W/K licensees apply to the PO Dept., Century Bldg., Lisgar St., Ottawa, Canada, or its six regional offices. Canadians apply to the FCC, Washington, D.C. 20554. Travelers visiting elsewhere should allow at least two months for processing of requests. Write to ARRL HQ for details on a particular country.

Hancock, MI 49930

A VHF Band Scanner

The pan adapter has received a considerable amount of publicity and does a fine job for the HF (160-10 meters) ham. The pan adapter that covers 250 KHz is usually sufficient. The VHF ham, however, may want to observe 2 MHz or more of the band.

The band scanner to be described will cover the full 4 MHz of the 6 and 2 meter bands, if desired. The band scanner is sometimes referred to as a spectrum analyzer. Either term is ok but I prefer band scanner.

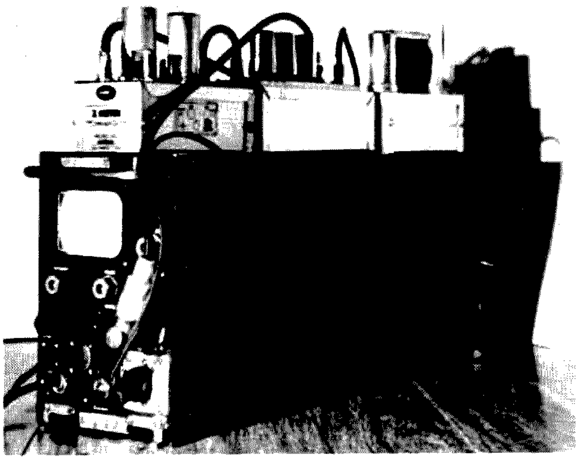
Pan Adapter vs Band Scanner

There is very little difference in the units. The pan adapter has the same input frequency as the *if* of the receiver and is usually connected to the receiver mixer plate. This arrangement keeps the received frequency centered on the shield of the cathode ray tube. The selectivity of the *rf* stages of the receiver reduce the signal strength of the signals either side of the center frequency. The pips, or displays, are progressively smaller as they are farther from the received frequency.

The band scanner uses a typical crystal controlled VHF converter with the same output frequency as the band scanner input. A two or three stage *if* amplifier is usually required between the converter and the band scanner to give a good distinct display of weak signals. An *rf* tap for the receiver can be made at the input or output of the *if* amplifier. The band scanner display is independent of the receiver tuning. If properly adjusted, the scanner will have nearly equal sensitivity over the entire band. The scanner cathode ray tube shield can be calibrated for direct frequency reading.

The Units

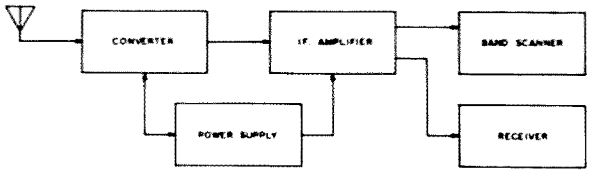
Band scanners are available on the surplus market so cheap that there is no advantage in constructing one. The scanner is easily repackaged to give it a neater and 'civilian' look, if desired. The conversion information



VHF band scanner. On top from front to rear are the converter, *if* amplifier and power supply.

that is sent with the IP 274/ALA10 or IP 69/ALA2 band scanner covers changing the power supply to 60 Hz (the original is 400 Hz) and changing the input to 14 MHz. All my VHF converters have 28-30 MHz output so I did not change the scanner input frequency. The IP 274/ALA10 and IP69/ALA2 scanners have the four standard oscilloscope controls: intensity, focus, horizontal position and vertical position. The scanner controls are; sweep limit, width, center frequency and gain. I removed the front panel power plug and replaced it with a plate and an ac outlet. The outlet is connected through the switch so the converter and *if* amplifier will be turned on and off with the scanner.

If you want to cover only 2 MHz of the band (I scan 144-146 MHz) the center frequency control may not center the scan. I use a converter output of 28-30 MHz so I injected a 29 MHz signal into the scanner input then turned the center frequency control to bring the pip as close to the center of the shield as possible. I backed the control



Block diagram of band scanner and associated equipment.

off about ¼ turn to allow for calibration then adjusted L 104 (scanner sweep frequency coil) to center the 29 MHz signal on the cathode ray tube shield. Touch up the scanner input and *if* coils for equal sensitivity at 28 and 30 MHz.

The converter can be constructed or purchased. Articles are readily available in past issues of *73* or the handbooks for those desiring to construct the converter. A poorly built converter can give false pips as the scanner will show any *rf* signal in the sweep range. The most common sources are self oscillation of a tube or transistor or excessive oscillator injection. Be sure your converter is adjusted for flat response over the sweep range.

I used a surplus 30 MHz *if* amplifier. If you prefer to construct your *if* amplifier *73* has a construction article on an integrated circuit 30 MHz amplifier on page 52 of the July, 1967 issue. Stagger tuning this amplifier should give it sufficient band pass and still have enough gain to operate the scanner. There are transistor and tube 14 and 30 MHz preamplifiers in the handbooks. These preamps will, of course, work as an *if* amplifier. The *if* amplifier requirements will depend, to a considerable extent, on the quality of the converter. The *if* amplifier should be tuned for flat response over the sweep range. Generally, an amplifier with 20-30 db gain is sufficient. The schematics show both capacitive and inductive coupling for the receiver *rf* tap at the *if* amplifier input and output. I use capacitive coupling at the output. If your receiver does not have an *rf* stage the local oscillator may radiate enough signal into the antenna input to give a false pip on the scanner. Connecting the receiver at the *if* amplifier output will minimize this condition. The receiver *rf* tap at the *if* amplifier input would be used by those that have a high quality receiver and the *if* amplifier would not aid the receiver.

Assembly

Due to the variations in the converters and *if* amplifiers that can be used with the scanner, and the simplicity of hookup, step by step instructions would be of little value. The interconnecting *rf* cables should be as short as possible. Use good VHF practice and no difficulty should be encountered.

Power supply requirements will depend on the units used.

Operation

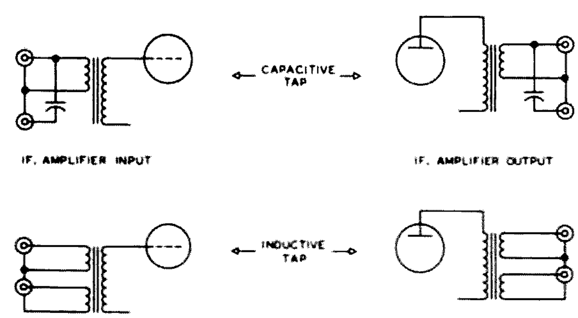
A band scanner will show the band activity, or lack of it, without tuning around and searching. The scanner can be used for analyzing signals as described in the panadapter articles. I find the scanner more convenient than my oscilloscope for aligning converters.

If you have more than one converter and antenna for a VHF band you may want to use separate converters for receiving and scanning. I use this system. The receiver coupled to the scanner lets me check out any other signals that I see without interfering with the QSO in progress. I put a relay in the scanner antenna lead and remove the converter B+ voltage when transmitting. The antennas are quite close together and the transmitter has a maximum output of 200 watts so I wanted to protect the converter from possible damage.

Some transmitters used in our local two meter net are crystal controlled and slightly off frequency so we have to tune for them. The scanner lets me see when they are on without wasting time tuning between transmissions to see if they are on.

Other Uses

For our CB friends who might be interested in a band scanner I would recommend a good *if* amplifier as no converter is needed. If, however, you plan to build a fancy scanner and calibrate the shield to show the



For capacitive tap use the smallest capacitor that will give adequate coupling. Start with about 20 pf and increase or decrease as required. For inductive tap make tap identical to the input or output winding and use minimum coupling. If input or output uses tapped coil use capacitive coupling. Some units may work better if band scanner and receiver tap are reversed.

channels, a converter is required. The converter will give you additional selectivity the same as a dual conversion receiver. Use a converter with a 14 MHz output and a 14 MHz *if* amplifier. There would probably be a small pip at 28 MHz from the converter oscillator. This would be out of the CB band so if you narrow the sweep to cover just the CB channels the pip would not show. Align the converter, *if* amplifier, and scanner for flat response over the sweep range as in the ham version. I would recommend a separate antenna. You might get enough isolation in the antenna relay so you could see your own signal when transmitting. I have not been able to do this with higher power.

Conclusion

Home brew construction of the converter and *if* amplifier is not recommended for the beginner as critical broad band alignment is required for satisfactory results. The band scanner has excellent broadband characteristics (max. 10 MHz) and alignment is not difficult if done carefully.

You will find a band scanner is an economical and fascinating piece of equipment for your VHF shack.

...WA8OIK

A Simple Inexpensive FM to AM Converter for Slow Scan TV and Facsimile

J. R. Popkin-Clurman, W2BK
134 Wheatley Road, Brookville
Glen Head, L.I., New York 11545

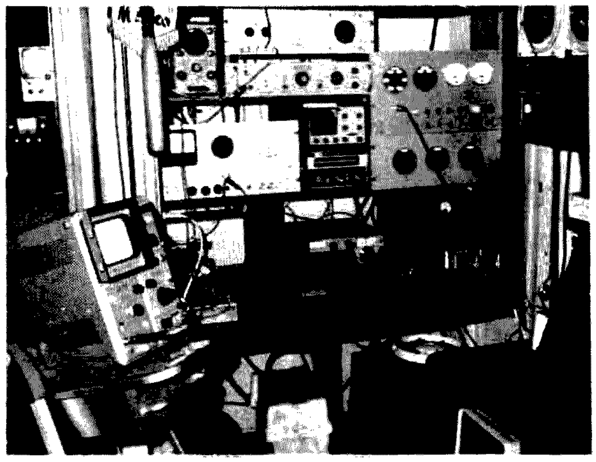
The heightened interest in slow scan TV and facsimile has brought forward a need for a converter to change the frequency shifted (FM) video or facsimile transmitted signal information into amplitude signals for feeding to a tape recorder, a slow scan TV monitor, a cathode ray oscilloscope (z axis modulated) with a photographing camera, or a facsimile machine. So far, the only available piece of gear appearing in surplus suitable for the above mentioned purposes has been the CV 172-172A/U, Frequency Shift Converter.

The CV 172-172A/U consists of the following elements, (Fig. 1):

1. Input
2. A band pass input filter
3. A limiter
4. Driver for the discriminator
5. A discriminator
6. A tuning indicator
7. A sound channel
8. Output

The tuning indicator, a dual "magic eye," defines the limits of the channel used, 800 cycle shift for black and white. The frequency limits in the CV 172 are 2300 (white) to 1500 cycles (black). A built-in monitor speaker is also included with the audio channel.

Analysis of the CV 172 reveals that many



View of satellite APT receiving equipment position: Tape recorder to right; FAX machine to far right; converter on right side of table.

of these elements can be dispensed with, since they are incorporated into a modern high selectivity receiver of the type used for SSB and RTTY. The irreducible minimum, then, consists of the input, limiter, driver, and discriminator (Fig. 2).

This simple converter is built from parts out of the junk box and uses two silicon diodes and one transistor (Fig. 3). In its quiescent state, it draws approximately 100 microamperes from the 9 V dc battery and approximately one milliampere under signal conditions. It would thus seem that the

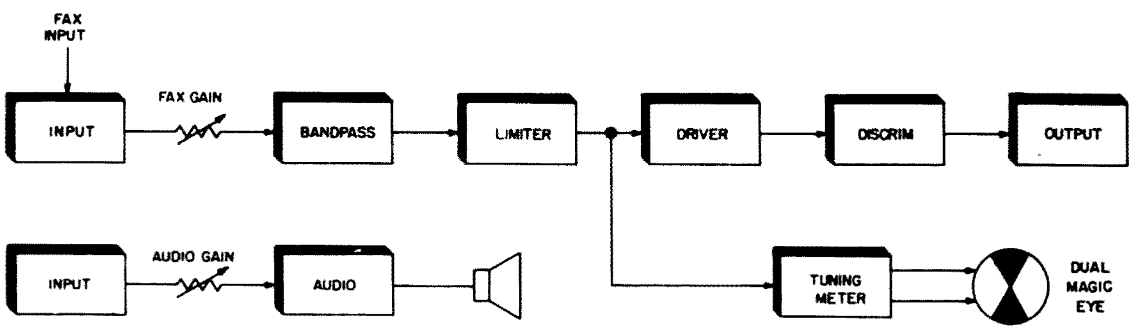


Fig. 1. Block diagram of CV172 showing all major elements.

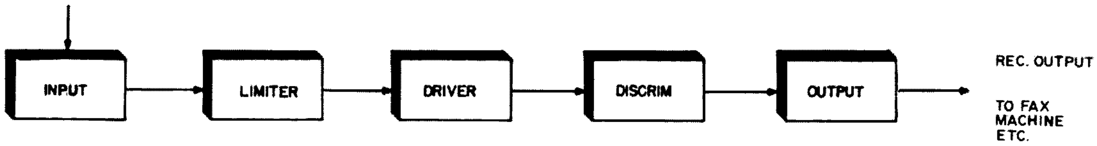

Fig. 2. Block diagram of absolute minimum components.

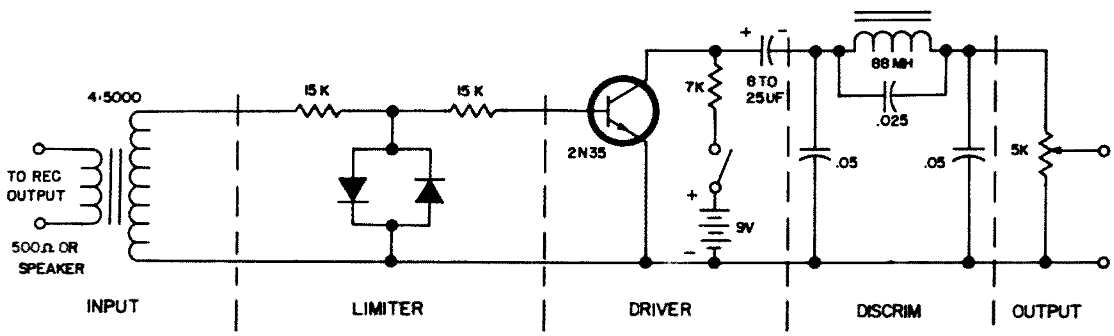

Fig. 3. Junk box converter using two diodes and one transistor.

switch incorporated into the unit might be an unnecessary luxury, since the life of the battery almost corresponds to its shelf life.

Any silicon diodes might be used, preferably those having similar characteristics. *Any* transistor may be used, NPN or PNP, with due care being taken to observe the polarity of the battery and the proper connections of the coupling electrolytic capacitor (**Figs.** 3 and 4). While this unit used one of the commonly available 88 mH surplus toroids, a horizontal width coil of the variable type, 45-215 mH (130 ohms), such as Stancor WC 14 or J. W. Miller type 6330 or 6324, might also be used. (All of the above parts were found in an old TV set, except for the silicon diodes, transistor, and 9 volt battery.)

The base (of 3/64 inch holed perforated metal) used was the cover for the horizontal deflection compartment of the TV set. 6-32 self-tapping screws lock in these holes nicely, (also from the TV set). The transformer used from the TV set was the speaker output wired backward 4 to 5000 ohms (estimated) and could be replaced by any transformer in the junk box having a good step-up ratio; even a 6.3 to 115 V filament transformer will work well.

In the author's particular case, being a RTTY enthusiast, and having full RTTY facilities, including a RTTY tuning indicator, the toroid of 88 mH frequency was tuned to 2975 Hz. When incorporated into the M derived low-pass filter used as a discriminator (**Fig.** 5), its frequency became slightly less than 2900 Hz. (If you wish to duplicate the CV 172, then more capacity is required across the trap inductance to tune to 2300 Hz.)

Connect the converter to the audio output of a receiver. Tune in a commercial RTTY station. As you tune through the RTTY signal (with bfo on), you will reach the point as seen on a scope (placed at the output of the unit), where only the mark or the space is left. The other one of the two signals will be sucked out or greatly attenuated by the tuned circuit trap of the discrim-

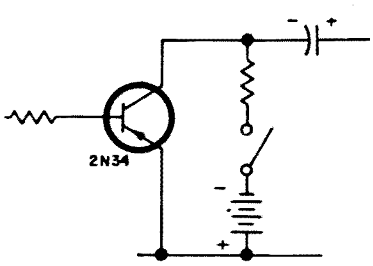

Fig. 4. Care must be used to observe battery polarity.

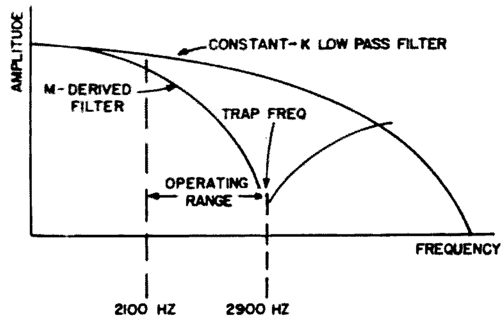

Fig. 5. Operating characteristics of discriminator.

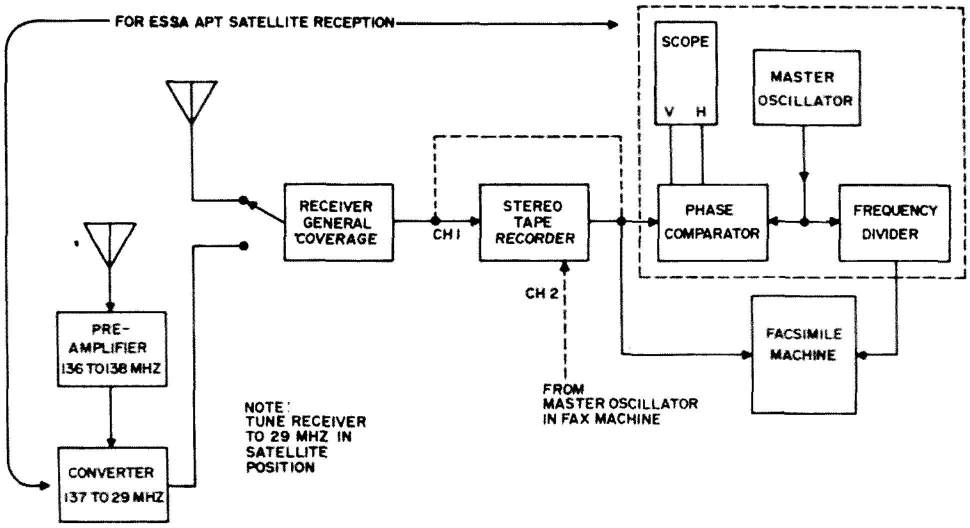

Fig. 5. Block diagram of the entire operating set-up.

inator. (Incidentally, this same converter, when combined with a rectifier and dc amplifier at the output, can be used to run a teletype machine.) The reason for using commercial RTTY signals is that they are far more numerous and easier to recognize, and their pulses are of longer duration than a station sending slow scan TV pictures or a weather map on facsimile.

When you have noted the correct positions of the tuning dial and the BFO for sucking out mark or space of the RTTY signal, you can then look for one of the reliable facsimile stations, such as Navy (NSS) on 3357, 4975, 8080, 10865, 16410, 20015 KCS or Air Force (KWAF) on 4502.5, 10185, 14550, and 19955 KCS (frequencies subject to change). These stations (when sending a picture) can be identified aurally by periodic tick-scratchings they make – like the sound of a phonograph record needle left running and repeating in the end-of-record groove of an *old* 78 RPM record with the volume turned up.

Often, when they are not sending fax pictures, they send "limit signals," one-half time black, one-half time white, at 800 Hz apart. These are ideal for tuning in the station. These limit signals are followed by phasing pulses, "ticks" only. They are then followed by a tone, then the picture. At the conclusion of the picture, another tone is sent.

The picture, as seen on the scope will be a series of pulses of audio at random times. (They will look like noise pulses.) Sweep of the scope should be set as slow as possible. If you are tuned to the wrong sideband of the signal, then you will see a kind of almost continuous signal with many dropouts. (This would give you a negative picture with white lines.) To reverse the situation, go over to the other sideband of the receiver and readjust the BFO. The tuning which gives you the cleanest baseline and maximum pulses is the correct one.

You will find this little converter every bit as satisfactory as the CV 172 and a lot cheaper! More fun too!

...W2BK

Confessions of an Appliance Operator

Or How to Ad Lib in Spite of the State of the Art

Edward R. Brace, W3ETQ
P.O. Box 372
Feasterville, Pa. 19047

Home-brew to me is what the XYL does with grapes. In fact, in my shack about the only home-brew addition is the junior op! This is not to cast doubt on the beauty of construction or testing. Nevertheless, because of the technical qualifications involved in "rolling your own" sophisticated electronic gear, I prefer to leave that excitement to members of the RCA net and those Ancient Modulation holdouts on 75. To me, the "stress interview" on 20 is much more enjoyable. Sadly enough, not enough hams feel comfortable when engaged in discussions other than those pertaining exclusively to their equipment.

I have often felt that such hams should be provided with a gentle guide to help them pump and drive their QSO's along – along lines that draw out the personalities hidden beneath the rubble of cliches and touch-and-go meaningless contacts which litter the ham bands. But this is not easy, for artificial guidelines restrict the natural blooming of the delicate flower or weed behind the mike. Be Maying like flowering is, why not try at least to offer a better and more fresh substitute than the dull weather report exchanges or information on the height of our antennas? This information may be important, but not as the sole nucleus of a QSO.

Each ham has his own specialized delight in amateur radio – curious as the specific choices may seem. Net operation and traffic handling for some, contests and county hunting for others, constructing and testing new antennas and home-brewing for still others. And then there is the hit-and-run DX man. Each interest is important and honorable, but without the personal touch ham radio can become dull and unprofitable as an exciting hobby. Without *personal interaction* and exchanging of cheek-tongued insults and information, viewpoints and prejudices, humor and confidences, sense and nonsense, we are not taking full advantage of the privilege we have open to us as licensed amateur radio operators.

Each amateur band ostensibly has a personality of its own. I, for example, have always considered 75 meters as tight and verbose and almost friendly; 40 meters is more open, but with copious quasiclosed Knights of the Roundtable; 20 meters is more brisk, because band conditions may change at the drop of a comment – thus necessitating economy of transmissions; 15 meters is generally considered a "DX" band, and it seems that more W's and K's call "CQ DX" on this band than all others (and it's amazing how often they succeed); 10 meters is volatile and especially sensitive to sunspots and low-power DX contacts. The remaining bands are not to be trusted. Especially by those of us who do not have the capabilities on 160, 6, and 2 meters. Moon-bouncers are an especially-especially seedy lot, and RTTY men should be placed under special observation. I refuse to mention those hams active in ATV!

But we return again to the old problem. Dull QSO's. Stereotyped. Mimeographed questions and planned answers. Let's rebel! Let's pin our next contact down and develop a line of conversation outside of that which might ordinarily be expected. Let's surprise him by being actually *interested* in where he lives, what he does to support his addiction to ham radio, what his opinion is on collecting dictionaries (only in English, of course!), how he feels about modern jazz in an oversexed society, what he considers the most important contribution the League has made in the last 50 years (QRX!), how he relates to the problem of the *skua* bird eating baby penguins (I learned that one from KC4USN), his etymological comment on why the 807 has been elevated from an electron valve to an edible-drinkable-item, et (basically) cetera. You get the point.

There are a lot a great guys hiding out

there behind mikes – let's try to draw them out. Let's find out what's happening – even on 75 meters! If the band stays open, let's not let them get away until we have had a meaningful exchange. And why not be more concerned about geography? Ham radio is the greatest "textbook" in the world, and most of us have never taken full advantage of it.

Although seemingly a contradiction in terms, reproduced below is a random sample – poorly developed – of the *Extra Top Quality Amateur Ad Lib Cheat Sheet.* The main idea is to be absurd but interesting. To spark something that virtually demands an answer – albeit a laugh or a groan. Like priming a pump, we may eventually put out-of-the-way remarks into the mouths of some of our more conversationally reticent ham buddies. At least we may make them QRT and thus clear the frequency for some hit-and-run DXers. We don't wish to encourage the "planned ad lib" – but let's at least attempt to emulate the open fun of our colleagues on that Grand Old Band – 75 meters. (And that's a lot of GOB, gang!)

1. What are you doing hiding out in a place like______?

2. If this vertical doesn't work out better, I'm going to melt it down and make a birdcage!

3. Your quad sounds fine; and it's great for drying sheets!

4. Your_______beam sounds great – if you don't mind a giant silver bird hovering over the roof!

5. Your audio sounds great – I didn't realize that mikes worked that well under water!

6. Don't worry about not getting out; your signal's probably healthy and clean, hiding out in Argentina.

7. I've always wanted to visit your state, but I could never get a visa (or: could never get clearance from the State Department).

8. Your quad sounds fine; they make great pelican roosts. But watch out for those 200-pound obese pelicans! The Department of the Interior frowns on this method of bird capture.

9. As the lumberjack said, see you a little later down the log.

10. I won't say the XYL here is against ham radio, but she did make me install the rig in a mobile home – forty miles away!

11. I own three SWR bridges – next month I'm buying an antenna to go with them.

12. I'm boning up for phone operation on 75 meters; I'm taking Caustic Remarks 305, followed by How to Squelch Breakers 103.

13. In order to get a QSO on 75, you have to be born there!

14. 75 meters is the St. Petersburg of the ham bands!

15. Did you hear about the robbery at the recent ham meeting in St. Petersburg? Someone stole 300 crutches!

16. Heard on 75: Your signal is weak here, OM. Only S9.

17. The roundtables on 40 meters are so involved and extensive that when one ham checked in, as a bachelor, he got married, his XYL had a son, and the son got his General in time to get into the QSO.

18. The QRM on 40 meters is very generous, politically – you have your choice of the Voice of America or Radio Moscow.

19. The rig here is a Kenmore washer, running about three horsepower into an aluminium clothesline up about five feet.

20. The antenna system here is 5,000 snails in cascade, fed by raw hamburger.

21. I won't say that I'm the epitome of Appliance Operators, but we *do* employ six First Phone men for general maintenance and equipment polishing.

22. I won't say the SWR here is unusually high, but it's true that the microphone radiates more than the antenna.

23. I realize that low angle of radiation can be desirable, but who told you to bury your antenna underground?

24. The antenna here is so high it was arrested by the narcotics squad.

25. I won't say the power here is low, but my nightlight draws more current than the rig.

26. Is it true that you have your DXCC certificate tatooed on your chest?

27. The antenna here is so low that it was knocked down by two angleworms playing leapfrog.

28. What are you doing playing ham, when it's obvious you'd be more qualified playing *bull*?

29. As Guy Lombardo said, see you around the band!

30. You should be pleased – just like the DX man who worked 43 countries in 26 minutes!

31. Yours is not to reason why; yours is just RTTY.

32. (Insert your best ad lib; Xerox; send to friends.)

And so it goes. The friendly fraternity of glib talkers. Truly interested in their fellow ham's scene and problems. Polished and poised, hesitant not to dash off the ultimate ad lib – duly practiced and recorded for tonal quality. Written and edited for punch. Eagerly awaiting the retort that stings, only to compose more clever spontaneous remarks at the next QSO. And, in spite of it all, perhaps something better will issue than the weather report or a detailed description of the antenna system. At least one would hope!

"I gotta keep an eye on him all the time or he's down at the radio shop spending money."

Household Helper In The Hamshack

A cleaning product known to housewifes as Scotch-Brite will find many uses in the hamshack. The exact parentage of this material is unknown to me, but it appears to be a form of plastic wool. It comes in several grades and sizes to fit the use to which it is put.

The homebrewer will find it excellent for cleaning printed circuit boards before soldering, polishing aluminum panels, and cleaning corrosion from antennas, ground rods, and the like.

I find the "ultra fine" grade to be the ideal filter for the blower on my linear. It not only catches the inevitable dust and lint, but also does a good job of silencing the noise of the air rushing into the intake. Try it! William P. Turner, WAØABI

Use of Frequency Charts

The selection of the optimum frequency is calculated from basic data published by ESSA, Boulder Colorado Research Center of the U.S. Government. The time is always in GMT, so 00 GMT is equal to 7 P.M. EST; 6 P.M. CST; and 5 P.M. PST; and so on across the chart. Due to our low power limitations we need to work as close to the maximum usable frequency as possible to reduce noise, so we bias the frequency selection toward the higher frequency bands when possible. During disturbances, try a lower frequency.

J. H. Nelson

What Am I Eating?

"King Sour Non-Butterfat Sour Dressing" made by American Whipped Products Company, Brooklyn. Alias ersatz sour cream. It is pretty good and you can hardly taste the quar gum.

DID YOU RECEIVE your QSL information rubber stamp? Six Lines, 2½ inches wide. Please send $2.00 to get yours. Other Stamps—$1.00 a line. Large Call Letter Stamp, $1.00—John D. Kirke Co. (K8SRA) 17711 Lakewood Heights Blvd., Cleveland, OH 44107. (See Dec. 73 adv., Page 102) All Stamps Postpaid. Guaranteed Value.

SWAN 500C, mint condition with power supply. Going to school. Asking $500. Best offer takes. Contact WA3JLY, John Martin, 804 W. Broad St., Quakertown, Pa. 18951.

THE AUGUSTA (MAINE) Amateur Radio Club will hold their 10th annual Hamfest at the Calumet Club, Route 104, Augusta, On 15 June, preceeded with an open house and get together on Saturday evening the 14th at the same location.

SELL HEATH HR-10B, calibrator, used very little, just factory aligned, overhauled. Asking $85 or cash offer. John Linn, Jr., 24 Stuart Place, Manhasset, N.Y. 11030.

HAMFEST sponsored by Lancaster & Fairfield County ARC at Derby Downs one mile south of Lancaster, Ohio on BIS Road, Route 793, June 8th. Gigantic Swap Shop. $1 registration with prizes every half hour. Main prize drawing. Good food at reasonable prices.

FOR SALE—One K.W. custom built transmitter. Pair 100ths in final, modulated by pair of 805s in class "B." Built in two matching cabinets measuring 40" wide, 68" high and 21" deep. Has 13 meters. Sacrifice $195. Hubert Ingalls, W1NQ, McCrillis Road, Nottingham, N.H. Tel. Epping 679-8862.

2-WAY MOBILE TECHNICIAN by S. Florida 2-way service corporation established 25 years. No beginners pleasel Minimum 5 years experience required on Motorola and GE. Send full resume including salary requirements and snapshot to Spencer Communications, 440 25th St., West Palm Beach, Florida 33407.

NORTH ALABAMA HAMFEST will be held August 17, 1969, in the cafeteria of John C. Calhoun State Technical and Junior College located north of Decatur, Alabama, on U.S. Highway 31.

WANTED ANTIQUE RADIO and wireless equipment. Also radio magazines of teens and twenties. Also buying supply catalogs, Duck, Manhattan, etc. Farrell, 2252 Dixie, Pontiac, Michigan 48055.

FOR SALE back issues—Radio TV/Electronic World magazines: 1953-1968; $1.50 ea. special issues $2. A.C. Gary, 378 W. Palisade Ave., Englewood, N.J. 07631.

B&W 5100s, 51-SB/B SSB generator, together $175. HR-10 excellent, just realigned $50. Want Heath supplies HP-23 or HP-13. Don Falk, Burton Hall; Oberlin, Ohio 44074.

FOR SALE—R392/URR receiver-mobile version of R390/URR-excellent condition with manual and accessories—$400. Brock, 2226 E. 28th St., Brooklyn, N.Y. 11229.

AMATEUR RADIO CERTIFICATE: Display impressive 8½"x11" personally endorsed certificate in your shack. Send $1 to Amateur Radio Certificate, Box 244, Miami (Kendall Br.) Fla. 33156.

SELL: COLLINS 51J-4 in Superior condition with cabinet 6KC and 3KC mechanical filters. $800. Warren Amfahr, WØ WLR/5, 3100 Brookview, Piano, Texas 75074.

REGULATED POWER SUPPLY KITS, .6-4 amp, $2.75 to $8.50. Zeners, thermistors, 25¢. 10A Triac, $1.75. Diodes, 5¢. Nixie, $5. Decimal Counter Kits, $3.50. Catalog. Murphy, 204 Roslyn Ave., Carle Place, N.Y. 11514.

FILTER-CONDENSERS: Aerovox Oil Filled 100 mfd. @ 3000 vdc condensers. $30 each. Basil J. Weaver, 1821-C-Ave M, Lubbock, Texas 79401.

SELL: NEW 4CX1000A with socket. Jennings 10KV 500 pf vacuum variable capacitor; Simpson plate and grid current meters; 5700 VCT plate transformer, 175 pounds. Package price $125 FOB. Pictures available, $1 refunded on purchase. WA6-THG, 6279 Stow Canyon, Goleta, Calif. 93017.

WANTED: Military, commercial surplus Airborne, ground, transmitters, receiver, testsets accessories. Especially Collins. We pay freight and cash. Ritco Electronics, Box 156, Annandale, Va. Phone 703-560-5480 collect.

HIGH VOLTAGE TRANSFORMERS wanted: Range 10,000 to 40,000 volts or higher. State voltage, current capabilities, and price. Bible, 409 Pennsylvania, Oak Ridge, Tennessee 37830.

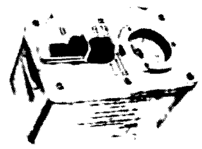
COMPUTOR BOARDS

Here is a fine value for parts and a fine breadboard. Each computor board contains about 50 diodes in addition to transistors, high-quality, low-voltage electrolytic capacitors, trim parts and precision resistors. Components are easily removed and have long leads. Each board is different. The plug-in board makes a fine breadboard or component board. Dimensions: 16"x4"x1". Weight 1 lb.
HCB..$1.25 P.P.

DUAL TRANSISTOR IGNITION SYSTEM

This system was made by Canadian Tire to sell for $35.00. These are Brand New fully wired surplus, not rejects. The extra high voltage coil provides smoother running at high speeds and longer plug life, and the lower current through the points makes for longer point life and faster winter starts. Special connector allows instant changeover to conventional ignition. Fully guaranteed, with instructions ready to install for 6 or 12 volt negative ground car. Closeout Special: DTI.......$10.00 P.P.

GEIGER COUNTER -GOV'T SURPLUS



"CD" Type Radiation Survey Detectors are in like new condition, with instruction manual, and straps. Picture shows typical unit. Bright yellow plastic case, waterproofed. Meter readings may be made from 0.01r/hr. to 50r/hr. Units are clean, and are offered untested, as is at a low price of $10.00 less batteries, battery price about $1.50. With life of 400 hrs. or intermittent operation.
CD MD. No. 710...$10.00 P.P.

BF Enterprises

SPECIAL ITEM SALE

VHF RECVR, Collins or Wilcox, 118-136 mhz, AM, 110 vac, makes first class net or monitor recvr, ex-FAA, was $125..........$60

DIGITAL COUNTER, 4 row, good condition..........$90

FREQ. METER, 100-500 mhz, .001% accuracy, excellent condition, heterodyne operation, 25 tubes plus crystal and original calibration book, 115/230 volts, civilian type LA-6 or military FR-6, was $495..........$350

FREQ. METER, 10-100 mhz, similar to above instrument, rack mount, 115/230 volts with original calibration book and schematic, best quality made, was $495..........$250

PULSE GENERATOR, Measurements Corp type 79A, required for all digital circuit work, 115 vac, was $88.....$49

Send SASE for list.
THE R&C WILSON COMPANY
Box 393, Littleton, Colorado 80120

3000 V @ 3μf brand new GE Pyronal oil capacitors $3 each. Can mail, 3-lbs. each shipping wt., FOB. P. Wandelt, RR#1, Unadilla, New York 13849.

NEED A VARIABLE CAPACITOR for that homebrew project? We may have what you need at more than 50% below regular amateur net. Send for free flyer. A.R.C. Sales, 181 E. Wilson Bridge Rd., Worthington, Ohio 43085.

3 PLASTIC HOLDERS will frame and protect 60 cards, $1—or 10 holders $3. Prepaid & guaranteed. Patent 3309805. Tepabco, Box 198N, Gallatin, Tennessee 37066.

SPECIAL CLOSE-OUT SALE. Rectifiers, Transistors, and many other Electronic Parts. Lowest prices. Send 15¢ for Catalog. Electronic Components Company, P.O.Box 2902 S., Baton Rouge, La.

FOURTH ANNUAL Mini-Hamfest, sponsored by the Rockford Amateur Radio Assn., August 17, 1969, at the Boone County Fairgrounds in Belvidere, Illinois. Lunch and refreshments.

SELL: HW-30, GR-64, Globe Chief 90-A, HG-10B. All good. $30 each. No manuals. You pay postage. WA3HWI, 7940 Gilbert Street, Phila., Pa. 19150.

WRL'S USED GEAR has trial-terms-guarantee! KWM1-$299.95; Swan 240-$179.95; TR3-$399.95; SB34-$319.95; Galaxy V-$229.95; Galaxy V Mk 2-$279.95; HX50-$199.95; Invader 200-$249.95; Galaxy 2000 plus linear-$329.95; Ameco R5—$59.95; HR20-$79.95. Hundreds more. Free "blue-book." WRL, Box 919, Council Bluffs, Iowa 51501.

HT-32A and TURNER MIC, $225, 75A4 #3234, 3 filters, 312A1 station control with Patch, $450, Hq-129X and spkr $90; TS-382 A/U osc. $125; Eico 667 checker, mint. $80; all items exc. cond. Also misc. parts and test eqpt. SSAE for list, W5LA, 1725 Valmont St., New Orleans, La. 70115.

B&W 5100-B Transmitter for sale. Best offer. Excellent condition. Contact Central Amateur Radio Association, 15 Centerville Road, Warwick, Rhode Island 02886.

ATTENTION CANADIAN AND NEW ENGLAND HAMS! The annual convention sponsored by Radio Amateur of Quebec Inc. will be held in Granby, Quebec, on the 27, 28 and 29th of June. Information and advanced registration from VE2BLP, Box 523, Granby, Quebec.

WANTED HRO COILS—all bands—any year for 5-7 or 50. Also want an HRO 5 for spare parts. Name your price. Wells Chapin, W8GI, 2775 Seminole Road, Ann Arbor, Michigan 48104.

FOR SALE: Hallicrafter SR150 ACps $350; Pr 4x150 Linear ps $50; Heath 10-12 Oscilloscope EF2 text and chassis $85; switches meters antennas etc., reasonable offers accepted. Geo. Shoner next to Library, Dugger, Indiana, 5 miles from US 41 on Ind. 54.

SBE 33 CLEAN never used mobile—$160. Walt Williams, 1706 Parkridge Terrace, Arlington, Texas. 817-261-9653.

THE EAST COAST VHF Society will operate station WA2WEB/1 on 432 mhz from Mt. Equinox, Vermont on June 21 and 22, 1969. The express purpose of the expedition is to provide amateurs on the East Coast of the United States with the opportunity of contacting the state of Vermont on 432 mhz.

The station will be on the air for approximately 24 hours for scheduled and non-scheduled contacts. Schedules are requested from interested amateurs. Write: East Coast VHF Society, P.O.Box 1263, Paterson, N.J. 07509. All correspondence and schedules will be confirmed prior to expedition.

RTTY GEAR FOR SALE. List issued monthly, 88 or 44 mhy torroids 5 for $2.50 postpaid. Elliott Buchanan & Associates, Inc., 1067 Mandana Blvd., Oakland, California 94610.

WANTED: SCHEMATICS & instruction manual for Farnsworth model 600A camera & control monitor. Contact G.D.Petrizze, 2135 N. Allen Ave., Althadena, California 91001.

"TOWER HEADQUARTERS!" 11 Brands! Heights aluminum 35% off! Strato Crank-ups-low cost! Rotors, antennas and gear discounts. Phone patch $11.95. Catalog-20¢ postage. Brownville Sales Co. Stanley, Wisconsin 54768.

FOR SALE: HW32A in excellent condition, $89. with rugged homebrew power supply, $99.00. WA1IRU, Art Karis, 14 Caldwell St., Fitchburg, Mass. 01420 (617) 342-3469.

MINIATURE INVERTER Transformers, $5.50; Power your old-fashioned Toob Projects. Convert 6/12 vdc to 100/250 v @ 100 ma, diagram supplied, W6PJN, Box 611, Clovis Calif. 93612.

SALE/TRADE—POWERSTAT, 7.5 amp, 120V; Super Pro Power Supply; 4 mf @ 1500 v oil conds; Ham-Scan HO-13; Heath Scope #10-21; Drake 1A; 51J1; BC342 and P/S; Hugh Burnham, K6VNU, 2866 Magnolia Avenue, Long Beach, Calif. 90806.

FOR SALE: Ht-37 100 watts and HT-41 1000 watts, both $375; Heath SB-300 rcvr, $175. Telephone 516-295-5411.

BACK ISSUES QST, CQ, 73 and Pop Elect., 75¢ ppd. Galaxy 300 xcvr/power supply, $125. A. Assenza, 82 Florence Aven., Arlington, Mass. 02174.

TOROIDS 88 OR 44 MHY unpotted. 5 for $1.50 ppd, continental USA. SASE for list of other bargains. M. Weinschenker, Box 353, Irwin, Pa. 15642

FOR SALE: Heath HW-32, HP-23, SB-600, Cal., cables, manuals, $135. SX-101A, $225. HT-37, $225. Extras. All excellent. WA2VWG, 6029 56th Drive, Maspeth, N.Y. 11378.

SELL: Clegg Venus 6 mtr. transceiver, ac supply, mint condition. Original cartons, $300. WA8ZUA, 7230 Wilmington Pk., Dayton, Ohio 45459.

THE PALMETTO AMATEUR RADIO Club announces its Second Annual Hamfest to be held indoors at the State Fair Grounds, Columbia, South Carolina, on June 1, 1969. A dutch supper is in the planning for the night before. The Hamfest will feature swapping, a transmitter building contest, homebrew contest, antique radio display, FM and MARS Forums, and bingo for the XYLs.

FOR SALE: 75A4, Vernier knob, noise blanker, .8 & 3.1 khz filters, external compression amplifier 200 hz filter. $350. GPR 90 rcvr xtal calibrator, outboard product detector, vernier knobs, Tapetone converter 50-54 mhz. $250. Tristao galv. tower 54', 10-15-20 Hygain beam, rotator, you dismantle. $150. Shipping and packing receivers not included. Carl Thorsell, 1195 E. 77th St., Kansas City, Mo. 64131.

FOR SALE: HRO-7 with xtal calibrator. It made DXCC for me. $50 local only. Virgil Talbott, W6GTE, Monterey Pk, Calif. AN8-8868.

39TH-ARRL WEST GULF Division Convention August 15, 16, & 17, Amarillo, Texas. For an ideal summertime weekend of ideas, fellowship, entertainment, fun (and maybe good luck) you can't miss at $10.50 for registration. W5WX Panhandle Amateur Radio Club, Box 5453, Amarillo, Texas 79107.

TEST EQUIPMENT WANTED: Any equipment made by Hewlett-Packard, Tektronix, General Radio, Stoddart, Measurements, Boonton. Also military types with URM- ( ), USM- ( ), TS- ( ), SG- ( ) and similar nomenclatures. Waveguide and coaxial components also needed. Please send accurate description of what you have to sell and its condition to Tucker Electronics Company, Box 1050, Garland, Texas 75040.

Silent Keys

It seems passing strange to me that I have yet to hear of any sort of ham ghost story. Do hams who pass beyond suddenly give up the passion of a lifetime and find something better to do? It may be that there is something to this tale Dante passed along about hell and perhaps most of the DX'ers are there, hacking away with bent keys and crystals that won't oscillate. Their dial cables probably have a lot of slack too.

In all semi-seriousness, I wonder if any readers have had any hints from the next world about DX conditions there? Any ouija board communications? Automatic writing? Or even via a medium? I gather, after a lot of reading, that communications with the departed is rather well substantiated to all but the most closed of minds. The problem with getting through seems to be one of converting frequencies. . .time and again they try and explain to us that their "vibrations" are on a different wavelength than ours. Since this obviously is not electro-magnetic waves that are involved, we may just have a clue that there are other types of waves than electromagnetic.

Mediums seem to be people that are sensitive to the other frequencies. Converters. They usually are connected in, not without QRM and other noise, to a medium in the next world who acts as a second converter. The result can be a rather good circuit, but is frequently about like trying to work a YK long path on a weekend.

Merely being aware that there is a possibility of a spectrum other than our electromagnetic should be enough to get some experimenters working on the problem. I am not sure what we might do if we found out how to use a new spectrum. I suspect that it would tie in with telepathy, might well be instantaneous (which make wavelength hard to define) and spaceless (which is an obvious function of instantaneous). What do you think? Or would you rather not think about it?

Conversions of Commercial Equipment

In the past I have been somewhat reluctant to devote much space in 73 to detailed conversions of commercial equipments. The concept being that, no matter how fascinating the conversion, it would be of specific value to only a very small percentage of our readers. In cases where a conversion or modification would work with a number of different pieces of equipment we have gone right ahead and published the articles.

While this policy was good for the majority of our readers, it still had the drawback of withholding valuable information from others. Now I have a little scheme that may solve this problem. I propose to publish modification articles separately and make them available to those interested at a nominal price. The author would still be paid the regular price for his article. . .the readers who need information on their particular piece of equipment could get it. . .and we wouldn't have to fill up the pages of 73 with mods on commercial gear owned by 2% of our readers.

So, if you have worked out any interesting improvements on your gear, perhaps this is the time to sit down and write an article on it. Send in the complete schematic diagram with the article. While it is virtually impossible to print these in 73 because they take up too much room, we can easily include them in a modification booklet.

Proofing 73

Now and then an incautious reader has, in the past, offered to help us beat back the growing tide of small errors and typos in 73. Unfortunately we have never been far enough ahead to do anything as simple as that. Now that we are setting our own type right here in our own headquarters there is a glimmer of hope that we may someday have a few articles ready for publication more than one week before the presses start running.

If you would like to have a chance to look at some of our incredibly fabulous articles before publication and promise to read them, watching for obvious typos and unobvious author errors. . .and even downright mistakes. . .and return them at the next high tide, all done with the welfare of amateur radio in your heart (no pay, this means), then keep not your intentions a secret.

Confessions of an Appliance Operator

Thundering across the airways and reverberating from speaker cones throughout the length and breadth of "hamdom" has come, like the piercing wail of a cow with a stepped-on udder, yet another epithet with which to flail and degrade an ethnic group within the amateur radio fraternity, i.e., You! You! You! Unspeakable appliance operator, you!!!

By over-simplification, an appliance operator is one who does not build his own equipment. He allegedly has the intelligence of a mentally retarded and recently pole-axed ox, the energy of a three-toed tree sloth, thinks manual labor is a Spanish War hero, is as socially acceptable as a skunk-farming roto rooter man with an aversion to soap, deodorant and mouth wash (in fact, he supposedly possesses all the mandatory prerequisites for becoming one of Katy Winter's closest friends); and his family tree–always suspect–is believed to be something he's living *in* rather than descended *from!*

At this point, it is necessary to clarify what is and what is not an appliance operator. Those who build at least 60% of their equipment can be classified as "homebrew specialists" or "artisans", those who build 10% or less are "appliance operators." The in-betweeners, for the purpose of this article, don't count.

There is, however, one nebulous Tinker Toy group that assumes the aura of, and is tolerated by, the artisan. They, in turn, look down their noses at the pure appliance operator. These ersatz artisans, called Gahzinters or Gahzonters do, in fact, build their own equipment...Uh Huh! In KIT form! (Hell, I know a 75 year old li'l ole lady with arthritis, palsy, 60/60 vision who didn't know the difference between a soldering iron and the south end of a north-bound mule who assembled a 23" television kit–this hardly qualifies her as this year's nominee for the second lead in David Susskind's off-Broadway production of "Tom Swift and His Electronic Grandmother.")

The Gahzinter is theoretically superior to the appliance operator 'cause he really knows what goes on behind the front panel of his equipment. For instance, T1–the big

black whatsis–gahzonter the chassis, the little glass things gahzinter the little holes, then the chassis gahzinter the cabinet, the cabinet gahzonter the table and the plug gahzinter the wall socket! (Whoopee! electronic "silly putty.")

It must be obvious–even to the Gahzinter–from the title and tenor of this article that I am that most loathesome of all creatures, an appliance operator!

There are many reasons that a person follows the path of the appliance operator–lack of time–lack of interest–inaccessability of parts–ad infinitum–ad nauseum. My reasons are two-fold; I was born under an unlucky sign and am afflicted with the domino syndrome!

Astrologers tell us that there are only 12 signs of the Zodiac–a gross untruth: there is a 13th sign (Heinie, The Municorn). The name Heinie was selected as a tribute to two of the unluckiest Municorns of them all, Buster and Lotta Heinie(named by parents with a perverse sense of humor). Uncoordinated "Three Thumbed" Buster Heinie, so uncoordinated, he couldn't walk and whistle at the same time, and his twin sister, Lotta, a cross-eyed seamstress who couldn't mend straight; both came to untimely ends. Buster traveled to India to take up snake charming and, on his first solo mission, was assigned a "deaf" cobra. Lotta, out of remorse, became a street walker in Venice.

The symbol for the thirteenth sign, The Municorn (a cross between a large mule and a pygmy unicorn) was selected because it epitomizes a continuous exercise in futility.

The male Municorn (the Gaffer) retains its pygmy size and horn, while the female (the Frail) remains large and mule-like.

The Municorn, understandably, proved to be unprolific and soon became extinct. For each time the Gaffer approached the taller Frail, it was necessary to get a running start and launch himself into the air. (Now, the Gaffer, like the Koala bear, feeds exclusively on eucalyptus leaves and is in a constant state of inebriation–accompanied by the blind staggers which tended to limit the height and often times the direction of his hunger). Keeping in mind that the Gaffer retained the one single horn directly in the center of his forehead and his inability to gain the required altitude, it was not an uncommon sight to see a Frail–with a startled, open-mouthed, buldging eyeball pained-look on her face–vaulting high into the air or dangling uncertainly from the uppermost limb of an apple tree.

You can usually recognize a "Municorn" by the soldering iron burns on his fingers, the crazy-quilt outer skin of band-aids, the battery acid holes in his clothes, singed eyebrows from overfilling his Zippo, and the cauliflower ear he got when, trying to put a "gleem" in his xyl's eye (he goosed her while she was brushing her teeth and she damned near decapitated him with the bathroom dixiecup dispenser.

My second drawback, the domino syndrome, is a series of cataclysmic and destructive events set in motion by one single action which blossoms out in mathematical sequence inversely proportional to their desirability.

It can best be explained by an example. Let's say it snows: you haul out your snow blower and attack the mountains of snow, accidentally gulping up the aluminum driveway reflector which feeds through the chute with unbelievable force and, like some vindictive NIKE missile, imbeds itself in your newest $65 snow tire.

The tire, suddenly devoid of air, goes wham! The rear end goes plop! And the shock absorber goes snap! pffsst! clunk! Now, while you're watching these mechanical hi-jinx, you absent mindedly run the snow blower into your son's brand new Flexible Flyer, which he'd brought out just before the snow fell, transforming it immediately into basket weaving material, bend hell out of your impeller blades and send slivers into everything within a radius of 50 feet–including the omni-present goggle-eyed poodle.

Thence, in a fit of pique, you become, for the moment, an olympic hammer thrower and hurl your snow blower high into a fir tree, ripping down your phone lines in the process.

This, essentially, is the domino syndrome.

The hardest part, of course, is trying to explain–coherently–to the phone repairman (who, when coming up the drive has wonderingly observed the harpooned snow tire, the pile of sawdust, the twisted sled runners and your wall-eyed hedgehog-like poodle and is now peering at you with a jaundiced eye,

ready to burst into frenzied flight at your first suspicious move) exactly what snapped your phone line and precisely what your snow blower is doing, roaring away, in a fir tree 30 feet above the ground.

Not long ago, I was involved in a domino repair project that began, as they all do, innocently enough. I had discovered that with two TV's coupled together on the same antenna, the broadcast receivers in the upstairs bedrooms buzzed loudly. Investigation showed that a simple two-set coupler eliminated the problem. I screwed the coupler into a shingle and, as usual, ended up needing about two inches of extra twin line. I gave a slight tug—just enough to not only pull down the twin line, but the antenna and a cleverly secreted hornets nest, complete with its irate inhabitants!

Later, after disengaging myself from the aluminum monstrosity, hiking back from the tar pit where I'd gone to escape the now homeless hornets and applying unguentine to the now-swelling stings, I climbed the roof and successfully re-installed the antenna. Unfortunately, on the way down, I slipped and clutched at the rain gutter for support. One end let go and I swung, pendulum fashion, back and forth past the kitchen window where my xyl was conducting a suburbian covin—a koffee klotch—with a local Gossiporter (Gossip/Reporter). (A Gossiporter—there's one in every neighborhood—is the end product of careful selective breeding during which the brain is completely disconnected from any thought processes and left to control only the dynamics for muscular activity. Since the brain no longer functions, the eyes and ears are left to absorb bits and pieces of information seen through curtained windows, heard over the back fence, or just imagined. These bits and pieces are assembled at a central point which I sincerely suspect is located slightly below the bottom-most verterbrae in that portion of the female Gossiporter's anatomy which looks the most ridiculous in slacks or shorts. There, it is embellished, distorted and transmitted to the tongue—a perpetual motion muscle—which oscillates at a fantastic rate of speed and in a screech that will peel paint, break glass and give every dog in the county an earache!

As I swung back and forth loudly scream-

ing for aid and assistance, I heard the scorched tongue visitor exclaim, "Good Lord! there's a huge bumpy faced 'ape' swinging outside your window!" To this, my xyl replied, "Don't pay any attention. That's my husband, the Dingbat! Yesterday he was playing Lloyd Bridges in the septic tank and today, apparently, he's Tarzan!"

The other end of the rain gutter finally let go and I sailed in a beautiful arc and was unceremoniously deposited into our utility trailer which, predictably, was filled to overflowing with a week's greasy garbage, a number of dust-filled vacuum cleaner bags and several shovelfulls of rabbit droppings from our pet rabbit (my children, little sadists that they are, they take after their mother, call the rabbit droppings, "fat raisins)."

Now, I've heard of being tarred and feathered for some heinous crime, but to be unguentined, garbage-greased, dusted and rabbit raisined should be reserved as a Rettysnitch for failing to prostrate oneself in the direction of Newington, Connecticut, during the 2100 broadcast, omitting a genuflection at the mere mention of the Newington deity—the spark gap—or for using Wouff Hong's name in vain. (Incidently, I understand that the National Simian Society is also located at Newington, Connecticut—there must be some moral significance in that fact somewhere!)

Naturally, I had an audience that burst into immediate and uncontrollable, hysterical laughter, claiming that, as I climbed out of the utility trailer, I looked not unlike a giant animated, slightly fuzzy and extremely malodorous toll house cookie.

To make a long story short, after de-raisining myself, I finally managed to remove the buzz from the broadcast receivers, but not before I'd discovered that the holes I'd drilled in the shingle were letting rainwater into the cellar and managed to drop the largest of the AM receivers on my foot.

Sitting, ankle-deep in rainwater, repairing the AM receiver was the project I was involved in when I first heard the phrase, "appliance operator!"

I'd just finished one of my better solder joints—slightly under an ounce of solder on the terminal board. Hearing the phrase appliance operator caused me to pop a diode and solder both my wedding ring and Timex watch to the B plus.

In an attempt to loosen the ring and watch, I overheated the connection, spoiling my solder joint, and accidentally slid my right thumb down the soldering iron, burning the thumb, my ring finger, left wrist and splattered boiling solder into the most inappropriate spot in my lap - yeah! in fact, it went right through the button holes—talk about lead in your pencil...wheee!!!

I screamed and leaped to my feet—the AM receiver still attached to my left wrist. I was sucking on my burned right thumb, trying to extinguish the fire and shake loose that damned AM chassis when I noticed my father-in-law poke his head into the shack. He looked at me sadly and shook his head and, turning to my xyl, said, "Daughter, please don't look in there—puulleease!!!—the damn fool is hopping around like a 230-pound sea numph, doing what appears to be a semi-lunar fertility rites dance, waving a radio over his head with his left hand and alternately sucking on his right thumb like a middle-aged male counterpart of Lolita and whomping himself on the lower abdomen—or crotch—which, believe it or not, appears to be on fire! If that clot-headed wahoo ever starts fanning with the other hand, he's gonna start riding side-saddle, need a transplant, sound like Wayne Newton and you'll be able to hear the 'top forty records' booming out of his navel. It wouldn't surprise me if the jerk yelled, 'Shazzam!' and leaped out the window!"

All this happened one evening at—for the ham: 2130 local—for the swl: 9:30 p.m. and for any Citizen Bander who may be having this read to him, that's when the little hand is on the 9 and the big hand is on the 6 and it's dark outside.

For what they're worth, these are my reasons for being an appliance operator.

In order to co-exist in the Artisan/Gahzinter world of amateur radio it has become necessary to devise a two-phase system to make it appear that I am a non-appliance operator. I've listed them here in the hope that they may help others in the same predicament.

Phase 1 (Making your shack look non-appliance operator). Assemble the following:

a. 1 ea. ½" wire brush to remove all the factory paint and lettering and give your equipment that "Spirit of St. Louis" look.

b. 1 ea. Dymo labeller to relabel all the lettering you just wire brushed off. (A magic marker is optional for the purist). Be sure to over-label everything—a light switch should read, "Switch," "Lights," "On-Off," "Up and Down."

c. 1 ea. pop rivet gun (remove all factory permanent screws, nuts and bolts and replace with pop rivets).

d. 1 ea. pkg of slightly rusted machine screws for replacing non-permanent fasteners.

e. 1 ea. package of assorted knobs, no two alike in size, shape or color.

f. 1 ea. can of spray crinkle paint complete with "paste on" paint runs.

Points to remember for Phase 1:

a. Always have a chassis or two laid out on the bench with a Sams photo-fax laying beside it.

b. Maintain a number of suspicious looking wires dangling from various and sundry places—give the impression that one false move by the visitor will instantaneously turn him into an unrecognizable cinder or arc weld him to the thunder jug in the corner.

Phase 2 (Second, but by far the most important, in co-existance is sounding like a non-appliance operator.

1. Break in on a net or round table at the most inopportune time to ask how your signal sounds since you substituted 8298A's for 6DQ6's in your final. If someone should fall into the trap and ask what an 8298A is, you can assume a pompous self-righteous air and inform him that to a dummy, that's a 6146B.

2. Be sure to be always looking for some obscure item—perhaps a transformer with one secondary of 5,000 volts, one at 7.3 volts and one at 1.9 volts—all at 2 amps or possibly a .007894 mfd electrolytic rated at 52 kvdc. One disadvantage to this is that you're liable to get some of this junk.

3. Be critical of all other signals. Make it sound as if you were carefully scrutinizing them on a scope (homebrew, of course). He's always drifting, flat-topping or pushing it a little too hard. (I had one fella give me a complete analytical observation of my signal. I later found out he was running mobile at 70 mph—half in the bag—and a hitch-hiker was tuning the rig.

4. During qso's, nets or roundtables, always miss a turn; then boom in explaining that you were just putting the finishing touches on your final stage.

5. If the other station is using a transceiver, keep coming up a little higher in frequency until you've reached the extremity of the band.

6. Become a specialist in some practically unknown subject, like the comparative value of aluminum waveguides as opposed to galvanized waveguides.

7. Become expert on one tube and its exact replacement. Be able to argue the nonexistant merits of each.

8. During qso's, slowly insert carrier into your SSB signal, or slowly reduce your output until someone brings it to your attention. Then correct it.

9. Install a toggle switch in your mike cord. By flicking it a few times during transmissions, you'll give the appearance of "breaking up."

10. When asked about your equipment, tell 'em it's home-made—home modified, altered and destandardized equipment.

11. Assemble a glossary of epithets concerning those "durned appliance operators."

12. So that you won't sound like a young whippersnapper, keep a memorobilia folder containing a list of old time operators, info on old radio shows, a sheet of "I remember when..." items.

Incidently, if you need any good unused ideas, let me know. I'm running a "going out of mind' sale...

Treat your fellow radio amateur as if he were someone special...he is!!

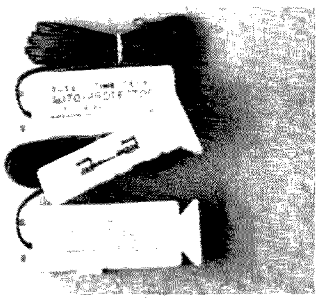
...K1YSD

MOVING?

Every day we get a handful of wrappers back from the post office with either a change of address on them or a note that the subscriber has moved and left no address. The magazines are thrown out and just the wrapper returned. Please don't expect us to send you another copy if you forget to let us know about your new address. And remember that in this day of the extra rapid computer it takes six weeks to make an address change instead of the few days it used to when we worked slowly and by hand.

New Auto Theft Protector

Do you live in an area where car theft is high? Are you afraid of going to a movie, only to come out and find your car and mobile equipment gone? If so, then try installing the Bussman Time-Delay Auto-Protector. (Bussman Mfg. Div., 2536 West University St., St. Louis, Mo. 63107).



The top protector has the activator arm removed to show ease of access in replacing fuses.

The heart of the protector is a time-delay fuse contained in a small hard plastic case. It's easily mounted in the glove compartment completely out of sight. The wiring is not tricky and connections are made between the thin ground wire leading from the distributor and coil (**Fig. 1**).

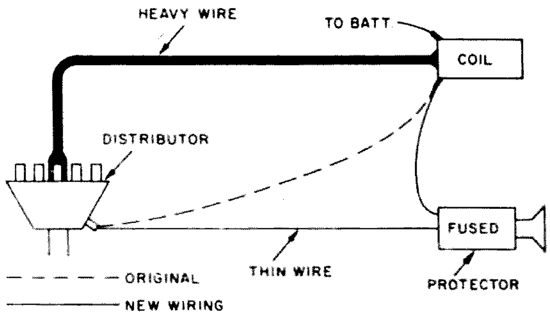


Fig. 1. Hookup of protector is very simple.

Anyone who tries to start the engine with the protector in the on position will find the engine quitting within one minute or less. When this happens, a thief is not going to take the time to look under the hood for problems, he's going to abandon the car. Remember, most thieves would rather drive your car to a safe spot before they strip it or try to take out your radio equipment.

The Auto-Protector sells for a little under $5 and can save you thousands in grief.

The Ancient Modulator

With the opening of new 160 meter frequencies and the tenacity of AM operators on VHF, a low power modulator can be quite handy in the shack of either a beginner or old timer. when a power supply and switching are included, it can provide power and control to any *rf* unit that is plugged into it. Let's take a look at this handy unit, and see how it was built.

Design

The first step toward bringing any project to life is to decide what is desired with respect to performance, and compare this with what is available. However, in this case, the parts in the junk box made the decision. Power transformers that would deliver 400 volts were there, and since 807's and 1625's were present in large numbers, the input of the rf amplifier would be limited to 40 watts, the plate current limitation of the tube at 100 milliamperes. This is still a very reasonable power level for vhf, and with the tubes and transformers operating at so conservative a level, long and dependable service could be expected.

Even with the low power required from the modulator, a pair of 1625's were used in push-pull as shown in **Fig. 1** T2, the modulation transformer, was a junk box item that does not exactly match the requirements. The required impedance is given by

$$Z = E/I = 400 \text{ volts}/0.1 \text{ amp} = 4{,}000 \text{ ohms}$$

So, it would be wise to consider this in the initial design. The unit used, however, had an impedance of 6,000 ohms, but no problems were encountered. The screen voltage was held at 300 volts by two voltage regulator tubes and the bias was provided by three nine volt transistor radio batteries in an attempt to run the modulators in class AB2. Again, these voltages are not exactly correct, but they are easily obtained and seem to work perfectly. A meter to measure the modulator plate current can be included, but it should not be considered as an accurate indication of the percentage of modulation.

The 6J5 was chosen to drive the 1625's because it was in the junk box. T1, the driver transformer, can be almost any single-plate to push-pull grids interstage audio transformer. The exact specifications of the one used are unknown. The one megohm gain control was placed in the grid of this stage as is customary to provide a good signal to noise ratio.

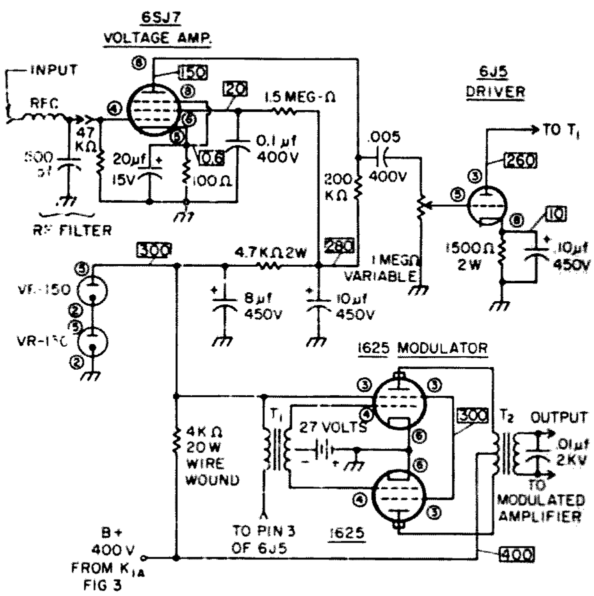

Fig.1. Modulator.

After a great deal of experimentation with twin triodes the 6SJ7 was finally chosen for the voltage amplifier first stage. It provides better than adequate gain from a single stage. The 47 K ohm resistor in the grid return of this stage was used to reduce rf feedback. It also reduces the gain of the stage considerably, but this was not a problem. A better solution would be a small rf choke in series with the grid lead, with a 500 pf capacitor from the grid to ground. RF

feedback may not be a problem on the lower bands, but it is sure to show up on the vhf bands as the howl that is so familiar.

Fig. 2 shows the power supplies, which require very little explanation. Again, components were selected for their reliability and availability. Two separate supplies were used to prevent the current variation of the modulators from causing a simultaneous drop in the voltage on the rf amplifier that would cause downward modulation. Two filament transformers were used to provide the twelve volts required for the 1625's and the six volts for the other tubes.

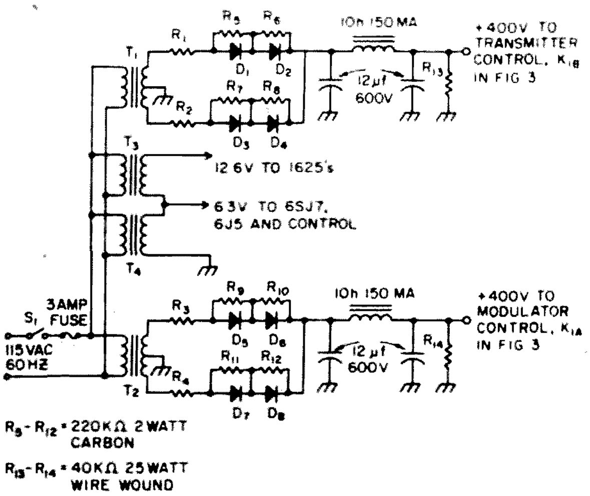

Fig.2. Power Supply.

The control circuit consists mainly of the relay and transformer shown in **Fig. 3** . T5 was used to provide isolation from the 115 vac line, and to provide six volts for indicator lamps. The isolation is necessary if one side of the microphone push-to-talk switch is to be grounded. The relay was used for rf switching as well as power and control switching. At vhf a coaxial switch would probably be desired for this application to provide low loss and shielding against feedback. The method used, however, was considered adequate considering cost and simplicity.

This is how it all started, now let's take a look at how it was built.

Construction

A standard 14 by 17 by 2 inch chassis was chosen along with the 19 by 8-3/4 inch rack panel and the side braces. They are all made by California Chassis. Handles were used on the panel because the unit is quite heavy. The layout and wiring are not critical except for the input audio stage, which should be carefully shielded to prevent hum and feedback.

If the relay is to be used for rf switching, the leads should be coaxial cables. In my case RG-58 was used.

Operation

The assembly can be tested one part at a time, first starting with the power supplies by measuring voltages, and proceeding through the amplifiers checking for output. Some typical voltages are shown in **Fig. 1** . These voltages were measured with a 20,000 ohm per volt vom, with all power applied and no load or audio signal. The final checks can be made with a suitable resistor or an output transformer connected to a speaker used for a load. Under no circumstances should the modulator be operated with no load. Even a small signal at the input can cause high voltages in the modulation transformer that can break down the insulation. Once the unit has been checked and is found to be operating satisfactorily, the output can be connected to the screen and plate of a suitable rf amplifier final stage.

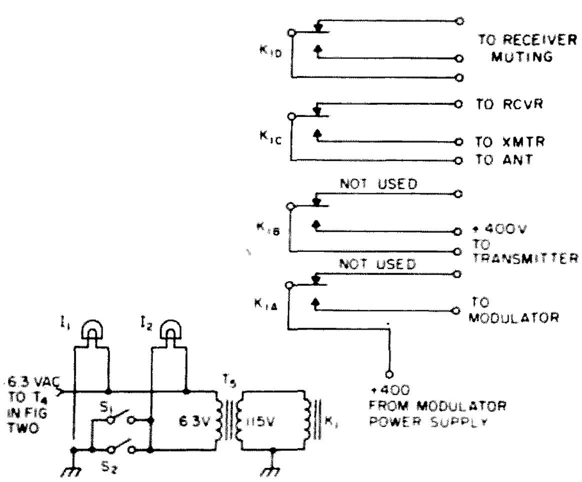

Fig.3. Control.

This unit has given excellent service and has been very dependable over a period of six months since the final version was put into service. The only failure was the result of a cold solder joint that had worked loose.

This modulator and power supply can become the basic starting point for a system made up of any number of low power *rf* units. Switching from one band to another can be accomplished by simply switching the filament power to each transmitter. The modulator could also be used in a more modest installation, as a part of a single transmitter. If this unit is used properly, it will give reliable and high quality performance in any system that its owner desires.

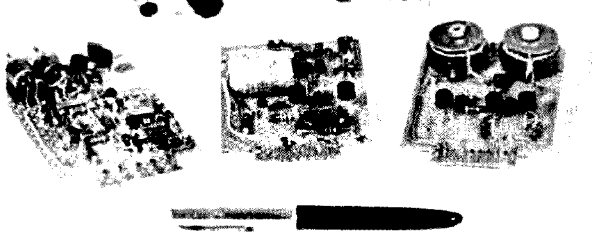
A Slow Scan Television Signal Generator

Louis I Hutton, K7YZZ
12235 SE 62ND St
Bellevue Washington 98004

For a two year period (1967-1968) I was granted permission by the FCC to conduct experimental tests with other amateurs authorized for SSTV transmissions on the HF bands. This is a relatively new mode of communication and has only recently been made available for general amateur use. The interested amateur will soon find that he must construct his own SSTV equipment in order to enjoy this new mode of communication. The first item necessary for SSTV reception is a monitor. Details on the construction of an economical monitor may be found in 73 Magazine for July 1967. Once the budding SSTV enthusiast has completed construction of his monitor, he wonders how can he test it? What is needed is some type of signal generator that would generate the various signals required to check out the monitor. Signals of this type are generated by a SSTV Camera[1], or a SSTV Flying Spot Scanner[2]. In either case a lot of equipment is involved in generating a test signal. The unit described in this article has been developed to provide SSTV test signals.

Generator with Panadaptor



Three circuit boards that comprise the generator

Circuit Description

The SSTV Signal Generator provides selectable test signals of the Sync, Black and White Frequencies, a variable Grey Scale signal, a vertical Bar pattern and a variable Dot-Bar pattern. The sync signals are stabilized by synchronization with the 60 Hz power line frequency.

The transistors Q1 and Q2 are used to shape the 60 Hz power line frequency sine wave into a square wave so that it will stabilize the horizontal frequency miltivibrator (Q3 and Q4) at 15 Hz. The 8 second per cycle vertical oscillator (Q5 and Q6) is frequency stabilized by inter-connecting the horizontal oscillator through the IN-648 diode and the .047 coupling capacitor. Sync pulses are taken from the collectors of Q4 and Q6, combined and fed to the sync amplifier Q10 and modulator Q11. The vertical sync pulse is 30 ms long and the

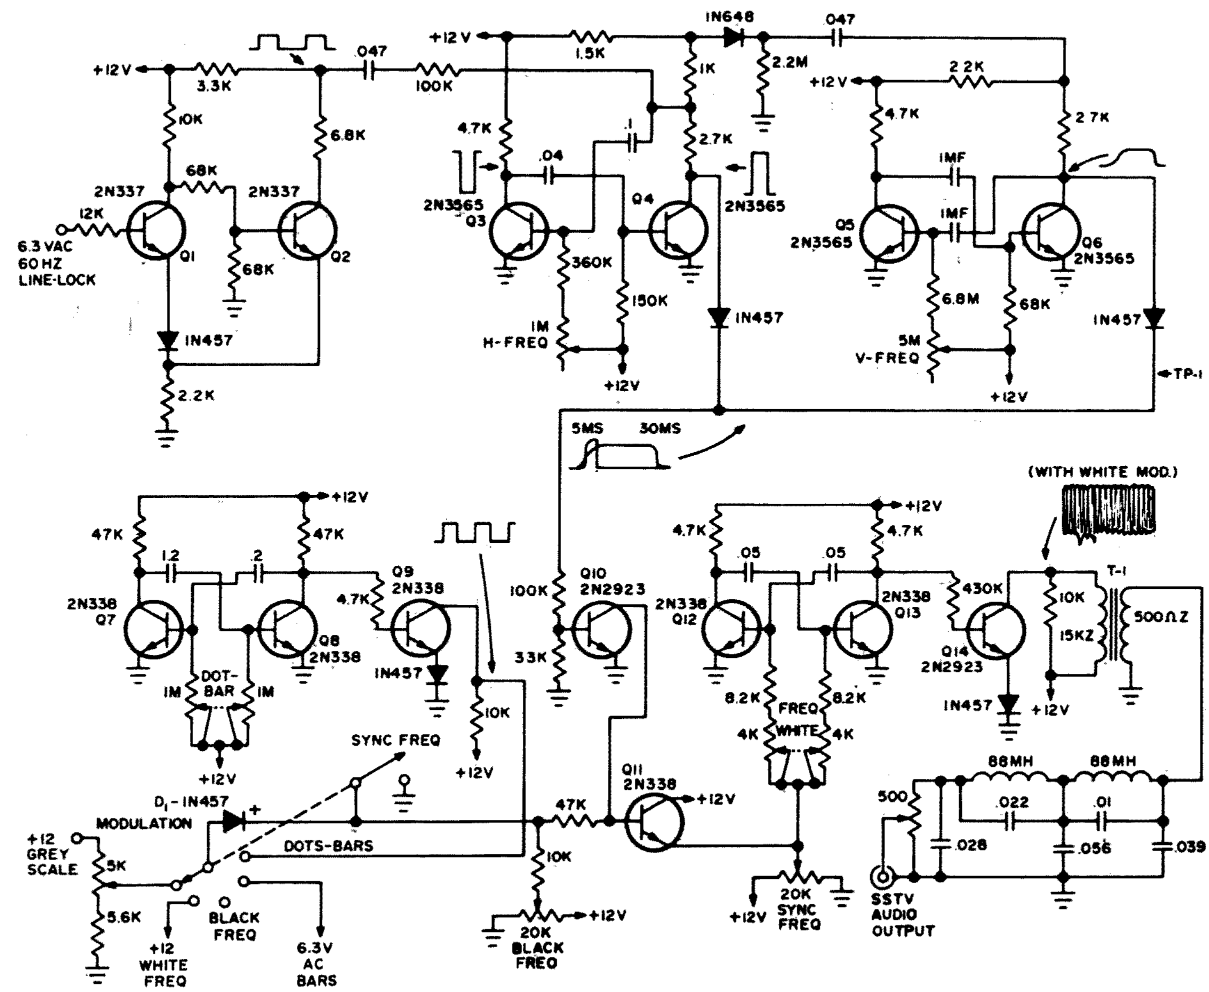

Fig.1. Schematic of SSTV signal generator.

horizontal sync pulse is 5 ms long. The Dot-Bar oscillator (Q7 and Q8) output frequency is manually adjustable from approximately 7 Hz to 80 Hz. This signal is amplified by Q9 and is connected to the Modulation Switch Dot-Bar position.

The 1500 Hz SSTV sub-carrier oscillator (Q12 and Q13) output is amplified by Q14 and is connected to the low pass filter through the step down transformer T1. The low pass filter rounds off the square wave output from the sub-carrier oscillator and attenuates any spurious frequencies generated above 3000 Hz. Positive going voltages appearing at the base of Q11 will shift the sub-carrier oscillator up in frequency and negative going voltages will shift it down in frequency.

The sync pulses from the sync oscillators are of the proper polarity when they appear at the base of Q11 to cause the 1500 Hz sub-carrier oscillator to shift to 1200 Hz for the duration of the sync pulse. The positive

12 volts from the "White" frequency position on the Modulation function control drives the sub-carrier oscillator from 1500 Hz to 2300 Hz. In the "Grey Scale" position, the voltage is manually adjusted from a positive 12 volts to near 0 volts which in turn shifts the sub-carrier oscillator to any frequency between 2300 Hz and 1500 Hz (White to Black).
